. Hunter McGuire of Richmond, Virginia, reports two cases. They were ovaritis; Lister's antiseptic method and laparotomy were used. "In both both ovaries were removed and the pedicles tied with carbolized catgut. result of the operation in one is eminently successful, while in the other there marked and continuous improvement, with a gradual subsidence of all trouble able to ovarian sympathy." Dr. Goodell sends two unpublished cases. operation in each case was begun *per vaginam* but finished by laparotomy. result in the first case was fatal; the indication was "a womb bulbous and ty with multiple fibroids." The second case recovered, the indication being rnicious menstruation and threatened insanity." Dr. Sims has had three s, all quite recent, and all successful. The indication for the operation in case was the occurrence of epileptoid attacks. The mode of operating is mentioned. Dr. Noeggerath has had ten cases, all done by laparotomy. e death occurred from sepsis and one from hemorrhage. Dr. Battey has had ee new cases. Dr. Trenholme writes "that the case in which I removed the e ovary is much improved but not well, and as for the other there is nothing w to report."

The total of cases thus collected is 130; of these 104 recovered and 26 died or a mortality of 20 per cent. The reporter counts Esmarch's case, although was one of hernia, and also all of Müller's, for although in two of them the ope tion was not finished, still the danger to the patient was fully as great.

Of the cases operated on by laparotomy, leaving out Dr. Sims's case as u certain, there was a mortality of 20.7 per cent. The cases by elytrotomy sh a mortality of only 19 per cent. Still this apparent advantage is more th counterbalanced by Dr. Goodell's experience, where in two cases he was una to reach the ovaries after opening the vagina, but had to increase the danger making a second incision

Later reports from Drs. Sims, Goodell, and West, show that all their ca classed above as doubtful, have recovered. This will bring down the death- somewhat.—*London Med. Record*, March 15, 1880.

Medical Jurisprudence and Toxicology.

Recovery from Opium Poisoning.

The recovery of an infant after a large dose of opium is so rare as to de notice. An instance lately brought before the Académie de Médecine is o the most remarkable on record. A teaspoonful of "laudanum de Sydenh was given to a child three weeks old, in mistake for syrup of chicory, which been prescribed for constipation. The mistake was made at 9 A. M., and immediately discovered and an emetic given without effect. M. NICHOLAS, records the case, saw the child soon afterwards, and ordered sixty grammes decoction of galls, and coffee in abundance. The first symptoms presented selves two hours later, and consisted in somnolence and evidence of na accompanied by tonic convulsions, after which the child passed into a stat prostration or rather of complete inertia, which continued during the day. T convulsive attacks were brought on by every attempt to administer a liquid the mouth, and gradually became more frequent and severe. Even the h ceased to beat during the syncopal condition which succeeded the attacks of vulsion. As long as they continued there was neither vomiting nor action of bowels, nor was any urine passed during the first twelve hours. During attacks of syncope, artificial respiration was kept up. Twenty times the c was thus apparently kept from immediate death. At 7 P. M. the somnol appeared to diminish; the child opened its eyes and looked around. The day witnessed a marked reaction; the pulse rose to 180, and in the afternoon little milk, with a few drops of brandy, was swallowed. The following morni the child was sufficiently recovered to take the breast, and on the fourth day well.—*Lancet*, March 13, 1880.

MEDICAL NEWS.

Colour-Blindness and Railroad and Steamboat Employés.—The Connecticut legislature has recently passed an Act authorizing the State Board of Health to prepare rules and regulations for the examination of railroad employés in regard colour-blindness. Every company in the State is obliged to hold such exami- ations on or before the 1st of October.

The U. S. Treasury Department has also recently issued an order requiring lots to be examined for colour-blindness before receiving licenses. These ex- minations are made gratuitously under the direction of the U. S. Marine Hos- ital Service.

A Four Years' Medical Course.—Harvard University announces that here- ter the course of study in the Medical Department recommended by the Faculty vers fours years, but until further notice the degree of Doctor of Medicine will tinue to be given upon the completion of three years of study. All candidates admission who hold no degrees in arts or science must pass a written prelimi- y examination in English, Latin, Physics, and any one of the following sub- s: French, German, Elements of Algebra or Plane Geometry, Botany. The mission examination will be held June 28th at Boston, Chicago, and Cincin- i; on September 27th at Boston only. The collegiate year extends over e months, beginning September 30th.

It is stated that the College of Physicians and Surgeons, New York, intends to tend its next winter course to seven months.

International Medical Congress of 1881.—The preliminary steps are now ing taken to hold an International Medical Congress at London, between the and 15th of October in the year 1881. The committee encharged with king the necessary arrangements consists of delegates from the Universities, lleges, and various Medical corporations of Great Britain.

Meetings of Medical Societies.—The following State Medical Societies will d their annual meetings in June:—

West Virginia Medical Society, at Parkersburg, June 2.
Massachusetts Medical Society, at Boston, June 9.
Minnesota Medical Society, at Albert Lea, June 15.
New Hampshire Medical Society, at Concord, June 15.
Ohio Medical Society, at Cleveland, June 15.

There appears to have been considerable misapprehension as to the day of eeting of the Kentucky State Medical Society. It is now authoritatively stated at the Society will convene at Lexington on the 19th of May, and not on the th, as has been heretofore announced.

The annual meeting of the American Medical Association will be held at New York, June 1st.

The American Neurological Association will meet in the same city on the 15th of June.

The Sixth International Congress of Ophthalmology will meet this year at Milan on the 1st of September, and continue in session four days. The address of the Committee of Organization, of which Prof. Quaglino is president, is Via S. Andrea, 13. Milan.

Dust Workers.—The prevalence of phthisis among artisans who are engaged in dusty occupations is well shown in a series of observations made in the hospitals at Breslau and Würzburg, quoted in the *Times;* the percentage of cases being classified as follows: Of those who work in metallic dust, the percentages were, needle-polishers, 69.6; file-cutters, 62.2; lithographers, 48.5; sieve-makers, 42.1; grinders, 40.4; compositors, 36.9; watchmakers, 36.5; type-founders, 34.9; engravers, 26.3; dyers, 25; varnishers, 25; painters, 24.5; printers, 21.6; beltmakers, 19.7; tinkers, 14.1. Of those who work in mineral dust: flint-workers, 80; grindstone-makers, 40; stonecutters, 36.4; plasterers, 19; porcelain-makers, 16; potters, 14.7; carpenters, 14.4; masons, 12.9; diamond-cutters, 9; cement-makers, 8.10. Of those who work in vegetable dust: cigar-makers, 36.9; weavers, 15; rope-makers, 18.9; millers, 10 9; bakers, 7; chimney-sweepers, 6.5; coal-miners, 0.8. Of those who work in animal dust: brushmakers, 49.1; hairworkers, 32.1; upholsterers, 25.9; fellmongers, 23.2; turners, 16.2; hatters, 15.5; button-makers, 10. Of those who work in mixed dust: glass-cutters, 35; glass-makers, 17.8; labourers, 15.1.—*British Med. Journal*, Jan. 31, 1880.

An Improved Nitrate of Silver Caustic.—Dr. SAWOSTIZKI (*St. Petersb. Med. Woch.*, March 25, 1880) called the attention of the Moscow Surgical Society to an improvement in the preparation of sticks of nitrate of silver. It consists in melting together five parts of nitrate of silver with one part of nitrate of lead, forming an argentum plumbo-nitricum. Sticks formed of this are preferable to those of the ordinary nitrate, as they are not easily broken, and can be pointed just like a lead pencil.—*Med. Times and Gaz.*, April 3, 1880.

Graduates in Medicine in 1880. (*Continued from* p. 252.)

College of Physicians and Surgeons (New York)	117
College of Physicians and Surgeons (Baltimore)	110

Making with the graduates reported last month a total of 1932 in the United States.

McGill University (Montreal)	30
University of Bishop's College	6

Jefferson Medical College, Philadelphia.—At a meeting of the Board of Trustees of this Institution, held on the 12th ult., HENRY C. CHAPMAN, M.D., was unanimously elected Professor of the Institutes of Medicine and Medical Jurisprudence, to succeed the late Dr. J. Aitken Meigs. Dr. Chapman is a grandson of the distinguished Dr. Nathaniel Chapman; he is well known as an ardent student of comparative anatomy, and has been a frequent contributor to the Proceedings of the Academy of Natural Sciences; he is the author of a volume on the "Evolution of Life," which was published in 1873, and elicited very favourable criticism. He now occupies the chair of Physiology in the Pennsylvania Dental College, and during the past winter he completed the late Prof. Meigs's course on Physiology at the Jefferson College to the great satisfaction of the class.

The Board of Trustees have also elected Dr. William Thomson Honorary Professor of Ophthalmology.

The Louisville Medical Schools.—The Louisville Medical Schools have agreed to advance their fees to seventy-five dollars, exclusive of matriculation, demonstrators, and diploma fees. It is reported that important regulations in regard to the time of actual attendance, the date of issuing tickets, etc., have been made.

Southeast Missouri Medical Association and Higher Medical Education.—This society at its last annual meeting adopted, by unanimous vote, the following resolutions:—

Resolved, That the Southeast Missouri Medical Association cordially indorses the action of Harvard Medical College, Bellevue Hospital Medical College, Medical Department of Yale College, Medical Department of University of Pennsylvania, Georgetown Medical College, and the Chicago Medical College, in their endeavors to elevate the standard of medical education by making a preliminary examination and a three-year course the requisite to graduation.

Resolved, That no member of this Association should receive any student unless said student first pledges himself not to enter any medical college in the United States, except those requiring a preliminary examination and a three-year course of graded instruction.—*Med. Record*, Dec. 13, 1879.

Transfer of the Library of the Medico-Legal Society to the New York Academy of Medicine.—The Committee of the Medico-Legal Society appointed to consider the advisability of the transfer of the library presented a favourable report, the consideration of which was postponed until the next meeting. The library is said to be the largest, with two exceptions, of its kind in this country.

Literary Notes.

The New Sydenham Society announces the fifth volume of Hebra on "Diseases of the Skin," and the third part of the Society's "Lexicon of Medicine and the Allied Sciences," as the first works of the series for 1880.

Henry C. Lea's Son & Co. have just issued Foster's "Physiology," edited by Dr. Edward T. Reichert, Demonstrator of Physiology in the University of Pennsylvania, and announce as in preparation a volume on "Electricity in its Application to Practical Medicine," by Dr. Roberts Bartholow, and a treatise on "Preventive Medicine," by Dr. B. W. Richardson, of London.

Mr. Presley Blakiston has just published in his series of Health Primers, "Our Homes," by Dr. Henry Hartshorne; and "Sea Air and Sea Bathing," by Dr. John H. Packard. He has in press Wilson's "Domestic Hygiene," edited by Dr. J. G. Richardson, and announces "A Dictionary of German Medical Terms," by Dr. Fancourt Barnes (to be published in London by H. K. Lewis).

G. P. Putnam's Sons announce "Contributions to Orthopædic Surgery," by Dr. J. C. Hutchison, of Brooklyn; "The Hysterical Element in Orthopædic Surgery," by Dr. Newton M. Shaffer, of New York; and "Ophthalmic and Otic Contributions," by Drs. St. John Roosa and E. T. Ely, of New York.

Mr. F. Leypoldt, of New York, the enterprising publisher of the *Index Medicus*, announces, that, notwithstanding the actual pecuniary loss incurred by the issue of this journal for 1879, he has determined to continue its publication for another year, in the hope that as it becomes better known to the profession it will receive the liberal support which it unquestionably merits.

The *Index Medicus* is issued monthly, and records the titles of all new publications in Medicine, Surgery, and the collateral branches, received during the preceding month. These are classed under subject-headings, and followed by the titles of valuable original articles upon the same subject, found, during the like period, in medical journals and transactions of medical societies. The periodicals thus indexed comprise *all* current medical journals and transactions of value, so far as they can be obtained. The compilation is under the supervision of Dr. John S. Billings, and Dr. Robert Fletcher, of the Library of the Surgeon General's Office, and their names are a guarantee of the ability and thoroughness with which the work is done.

It is superfluous to speak of the value of a monthly classified record of the current medical literature of the world, and its permanent establishment deeply concerns every student, thinker, and writer in the profession.

We trust that Mr. Leypoldt's appeal may meet with a cordial response in an enlarged subscription list, without which the permanence of the Index cannot be hoped for.

Resolutions of Respect to the Memory of the late Dr. Isaac Hays.—At the Tenth Annual Meeting of the Alumni Association of the Medical Department of the University of Pennsylvania, held March 15, 1880, the following resolutions were adopted:—

Resolved, That in the death of Dr. ISAAC HAYS, the late venerable editor of The American Journal of the Medical Sciences, and recently Vice-President of this Society, we mourn the loss of the most distinguished of the then living University Alumni, and one of the most revered and valued members in the world of the profession, whose best interests he so ably and faithfully defended and advanced.

Resolved, That the influence and example of his whole course, for more than half a century, of constant editorial, literary, scientific, and professional activity of the highest character, cannot be estimated in their value not only to the profession and its institutions of this country, but of the whole world.

Resolved, That we cherish his memory in common with that of our late president [Dr. George B. Wood] as one of the ablest, earliest, and most powerful advocates of the elevation of the standard of medical education in America, and we derive much consolation from the fact that they both survived long enough to enjoy some measure of reward in the recent advancement of their Alma Mater, and the certainty of progress which was so near to their hearts.

OBITUARY RECORD.—Died at San Francisco on the 27th of February, aged 74, HUGH HUGHES TOLAND, M.D., Professor of Surgery in the University of California.

Professor Toland was a native of North Carolina, was educated at Transylvania University, and studied in Paris under Roux, Dupuytren, and Lisfranc. He settled in San Francisco in 1853, and soon achieved a large and lucrative practice. In 1864 he founded a medical school, and at his own expense erected the building for the Toland Medical College, which in 1872 he transferred to the University of California, of which the college became the medical department. Dr. Toland was the author of "Lectures on Practical Surgery," published in 1877.

GREENE'S MANUAL OF MEDICAL CHEMISTRY—Just Ready.

ANUAL OF MEDICAL CHEMISTRY. By William H. Greene, M.D., Demonstrator of Chemistry in Med. Dept., Univ. of Penna. For the use of Students. Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages, with illustrations. Cloth, $1 75.

FROM THE AUTHOR'S PREFACE.

At one time, Bowman's little book on Medical Chemistry supplied the practical information ...ired by physicians in the application of chemistry to clinical research; but Bowman's ...ical Chemistry has long been out of print, and newer and better methods have arisen with ...development of chemistry; at the same time, no suitable text-book embracing these meth... ...appeared in English.

...hile, therefore, it has not been deemed advisable to follow the general plan of the former ..., a plan which at the present day is open to many serious objections, this little book is ...ed to fill the place so well filled by the other before its time of usefulness had passed.

...first part of the book is devoted to a brief description of the proximate principles which ...part in normal and pathological vital action, and the properties by which they may be ...ated from their associate compounds, and identified.

...the second part, the composition of the more important liquids and solids of the body, is ...ered, together with the processes by which they may be analyzed, both for the estima... ...f their normal constituents, and for the detection of compounds whose presence must be ...ed as pathological. The methods given in this part have been carefully selected as those ...will yield the most accurate results in hands not specially skilled in chemical manipula-

...third portion of the book treats of the detection of the more ordinary poisons. A tox... ...ical investigation is seldom undertaken by a physician, but cases may sometimes arise ...ich a comparatively easy preliminary examination may indicate either the importance of ...equent analysis by an expert chemist, or that suspicions of poisoning had been ground-... The directions here given will be found sufficient in such cases.

NETTLESHIP ON THE EYE—Just Ready.

STUDENT'S GUIDE TO DISEASES OF THE EYE. By Mr. Nettleship, Ophthal... ...ic Surgeon to St. Thomas's Hospital, London. In one neat royal 12mo. volume of 370 ...ges, with 89 illustrations. Cloth, $2.

...k is written in a careful and logical man-... ...though extremely concise, we have failed ...any evidence of ambiguity. It is rendered ...mpact and homogeneous by frequent refer-... ...by page number, to other portions of the ...repetitions are thus avoided, and we have ...rprised to find how much information our ...has succeeded in conveying in so small a ... A careful study of the book will well repay ...ral practitioner, even though it should serve ...a monitor. It is particularly useful in the ...gard, as the subject of treatment is pre-... ...is a thoroughly conservative manner.—*N. Y. ...ord*, March 6, 1880.

...thor has succeeded in touching upon about ...points, diseases, operations, diseases of the ...elation to general diseases, and has prepared a very acceptable book.—*Cincinnati Lancet and Clinic*, Feb. 7, 1880.

We are sure he has produced a useful volume. Its eighty-nine illustrations add much to its attractiveness. Full directions for examining the eyes are given. The descriptions of various operations and suggestions for local and surgical treatment, and the etiology of eye diseases, are done full justice to.—*Louisville Med. News*, Jan. 1880.

It is *multum in parvo*, containing all the leading points to be remembered in the pathology, description, and treatment of diseases of the eye. It will be found especially valuable in preparing for examinations. Practitioners will find it convenient as a work of reference, when they wish to refresh their memories in respect to the features of some affections.—*Cincinnati Med. News*, Jan. 1880.

MORRIS ON SKIN DISEASES—Just Ready.

DISEASES; INCLUDING THEIR DEFINITION, SYMPTOMS, DIAGNOSIS, PROG-...OSIS, MORBID ANATOMY, AND TREATMENT. A Manual for Students and Practi-...ners. By Malcolm Morris, Joint Lecturer on Dermatology, St. Mary's Hospital ...dical School. In one 12mo. volume of over 300 pages, with illustrations. Cloth, $1 75.

...ook is clearly and concisely written, and the ...is handled in a way calculated to be readily ...ible to students. The type is excellent, the ...eatly got up and of convenient size, and the ...ought to be very useful for the purpose for ...it is intended.—*Lond. Lancet*, Jan. 31, 1880.

...writer has certainly given in a small compass ...amount of well-compiled information, and his ...ook compares favorably with any other which ...anated from England, while in many points he ...ancipated himself from the stubbornly ad-... ...the errors of others of his countrymen. There is ...ly excellent material in the book which will ...pay perusal.—*Boston Med. and Surg. Journ.*, ..., 1880.

...physicians who would like to know something ...skin diseases, so that when a patient presents ...f for relief they can make a correct diagnosis ...scribe a rational treatment, we unhesitatingly ...mend this little book of Dr. Morris. The af-... ...s of the skin are described in a terse, lucid ...er, and their several characteristics so plainly ...that diagnosis will be easy. The treatment given in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that, in the whole range of medical literature of a like scope, there is no book which for clearness of expression and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author has handled his subject in a clear and concise manner, and as a text-book to students his manual will be found useful.—*Medical and Surgical Reporter*, March 27, 1880.

The author's task has been well done and has produced one of the best recent works upon the difficult subject of which it treats; there is no work published which gives a better view of the elementary facts and principles of dermatology.—*New Orleans Med. and Surg. Journal*, April, 1880.

HENRY C. LEA'S SON & CO.—Philadelphia.

NOTICE TO SUBSCRIBERS.

INCREASED INDUCEMENTS FOR 1880.

With a view of increasing the attractions of the "American Journal of the Medi-cal Sciences," and of bringing within the reach of all members of the profession th immense amount of information now presented by it and its accessory periodicals, th "Medical News and Library" and the "Monthly Abstract," the two latter will here-after be merged together, under the name of "The Medical News and Abstract," commencing January 1, 1880. The "News and Abstract" will consist of sixty-fou pages per month, handsomely printed, in a neat cover, and will contain all the materia heretofore presented in both periodicals, with the exception of the sixteen pages of th "Library Department." Its price will be Two Dollars and a Half per annum, inva-riably in advance, at which rate subscribers will receive nearly *eight hundred large octav pages per annum,* free of postage.

Not only will this monthly thus be in itself one of the cheapest periodicals offered t the profession, but it will be furnished in commutation, without charge, to advance-payin subscribers of the "American Journal of the Medical Sciences," the subscription t which will remain, as heretofore, Five Dollars per annum. For this very modera sum, therefore, subscribers will receive two periodicals of the highest class, a Quarter and a Monthly, containing in all nearly two thousand pages per annum, stored with t choicest original and selected matter that can be furnished by the medical literatur both hemispheres.

These terms may be recapitulated as follows:—

TERMS FOR 1880.

The American Journal of the Medical Sciences, published quarterly (1150 pages per annum), and The Medical News and Abstract, published monthly (768 pages per annum),	Five Doll per ann in advan

SEPARATE SUBSCRIPTIONS TO

The American Journal of the Medical Sciences, when not paid for in advance.	Five Dolla

The Medical News and Abstract, invariably in advance, Two Dollars and a Half.

⁂ Advance-paying subscribers can obtain, at the close of the year, cloth covers, gi lettered, for binding the volumes of the Journal (two annually) and the News a Abstract (one annually), free by mail, on remitting ten cents for each cover.

It is evident that only a very considerable increase to the existing subscription li will justify the unexampled terms thus offered, by which the equivalent of three or fo large octavo volumes is furnished, handsomely printed in a form for preservation, for th trifling sum of Five Dollars. Gentlemen, therefore, are respectfully requested to lo no time in remitting their subscriptions, to avoid the risk of disappointment from th exhaustion of the edition printed; and it is suggested that they may aid in renderin the enterprise permanent by kindly communicating to their friends the very great induce-ments thus offered.

The safest mode of remittance is by bank check or draft, or postal money order draw to the order of the undersigned. Where these are not accessible, remittances for th "Journal" and "News and Abstract" may be made at the risk of the publishers by forwarding in registered letters. Address

FOSTER'S PHYSIOLOGY—Revised Edition—Just Ready.

A TEXT-BOOK OF PHYSIOLOGY. By MICHAEL FOSTER, M.D., F.R.S., Prof. of Phy in Cambridge Univ., England. A new American, from the third English edition. Edi with extensive notes and additions, by EDWARD T. REICHERT, M.D., Demonstrator of perimental Therapeutics in Univ. of Penna. In one handsome royal 12mo. volum 1030 pages, with 259 illustrations. Cloth, $1 50; leather, $2 00.

AMERICAN EDITOR'S PREFACE.

The high reputation acquired, on both sides of the Atlantic, by Dr. Foster's "Text-Bo Physiology," as a lucid exposition of functional physiology, in its most modern aspect, has to call for an edition more thoroughly adapted to the wants of the American student. The of the author has presupposed an acquaintance with the details of physiological anatomy the student is accustomed to look for in his treatises on physiology. The absence of t details has rendered many parts of the work vague, if not altogether incomprehensible, an therefore proved a serious drawback to the usefulness of the book as an accompaniment t tures on physiology, as it is usually taught in our schools, and this deficiency the edit endeavored to supply, by brief notes and the introduction of a large number of illustratio

The almost limitless amount of material accumulated by modern research has rendered cult the task of selection and comparison, without exceeding the reasonable limits of a c nient text book. In his selection the editor has been guided by his experience in the wa students, and has endeavored merely to present, in the most concise form, such facts as would to be indispensable to a correct appreciation of the structure and function of the impo organs. In accomplishing this, his additions have considerably exceeded his expecta amounting to about 140 pages, including the illustrations which have been increased in nu from 72 to 259. If he shall thus have succeeded in rendering this admirable work better for the wants of the American student, he will feel abundantly rewarded.

Nothing has been omitted from the English edition, and all additions have been guished by insertion in brackets [—].

On the whole, the book can be called the standard work in the English language, while it has none superior in any other tongue. It is, perhaps, the only work in our language which represents physiology fully as an experimental science. Its completeness is admirable. The anxious student can find not only the actual facts of the science, but also the mode in which they were obtained. The author proves to the student not only a compiler, but a judicious critic.—*Journ. of Nervous and Mental Diseases*, Jan. 1880.

The work, since its first appearance, has continued to be one of the most satisfactory text-books on the subject that we have met with, and is in many respects peculiarly adapted to the use of practitioners. Those whose knowledge of the functions of organs was chiefly acquired a decade ago, and who have not since been diligent students of the subject, can little appreciate what advances have been ma can do nothing better than to give Dr. Foster's some careful reading.—*New Remedies*, Jan.

The author of this book is too well known siologists to require an introduction. His butions to this branch of science have him lasting fame. As an advanced thi writer his views and teaching are regard highest authority, and may be accepted as outcome of physiological research and st *Med. Journ.*, Feb. 1880.

An elaborate review at present is not requ only necessary to say that it is the best b immediate scope in any of the three lan far, at least, as our knowledge goes —*P Times*, Jan. 3, 1880.

THE SAME. Student's English edition, without notes or additions. In one smal volume of 804 pages, with 71 illustrations. Cloth, 75 cents.

EMMET'S GYNÆCOLOGY—New Edition—Just Ready.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Stude Practitioners of Medicine. By THOMAS ADDIS EMMET, M.D., Surgeon to the Hospital of the State of New York, etc. Second edition, thoroughly revised. very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; lea

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to th as an evidence that his labors have proved acceptable, has in a great measure height sense of responsibility. He has therefore endeavored to take full advantage of the opp afforded to him for its revision. Every page has received his earnest scrutiny, the c of his reviewers have been carefully weighed; and while no marked increase has been the size of the volume, several portions have been rewritten, and much new matter h added. In this minute and thorough revision, the labor involved has been much gre is perhaps apparent in the results, but it has been cheerfully expended, in the hope of r the work more worthy of the favor which has been accorded to it by the profession.

In no country in the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticize with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.*, Feb. 21, 1880.

The wide reputation of the author mak lication an event in the gynæcological wo glance through its pages shows that it is be studied with care. . . . It must al work to be carefully studied and freq sulted by those who practise this bra profession.—*Lond. Med. Times and Gaz.* 1880.

Emmet's work, taken as a whole, is so r tents, and so excellent in performance, professional man can profit himself by it, secured for itself an enduring place in logical literature.—*Prager Medicinische schrift*.

HENRY C. LEA'S SON & CO.—Philadelphia.

BUMSTEAD ON VENEREAL DISEASES—Fourth Edition—Now Ready.

ATHOLOGY AND TREATMENT OF VENEREAL DISEASES: Including the results ecent investigations upon the subject. By **Freeman J. Bumstead**, M.D., LL.D., late essor of Venereal Diseases in the Coll. of Phys. and Surg., New York, etc. Fourth edi-n, revised and largely rewritten with the co-operation of **R. W. Taylor**, M.D., of New rk. Prof. of Dermatology in the Univ. of Vermont. In one large and handsome 8vo. lume of 835 pages, with 138 illustrations; cloth, $4 75; leather, $5 75; half Russia, 25.

ble as were the previous editions, the have nevertheless labored so earnestly in ation of this one, that, as Dr. Bumstead s, the book is rather a new one than an old ed, it being fuller than the last by 131 ch chapter having been thoroughly worked brought up to the advanced standard of t day. The work is in every respect an ope, and worthy to be ranked with the matic treatises which this country has which would be ornaments to the medical of any nation.—*Archives of Dermatology*, 0.

editions of this always clear, comprehen-practical work have been received as *the* in this country, and the present volume tionably the foremost authority on the subjects treated to be found in any language. It will be many a day before a book more worthy of the American medical profession will overshadow this. —*Quarterly Epitome*, March, 1880.

We find that we have here practically a new book, —that the statement of the title-page, as to the fact that it has been largely rewritten, is a sufficiently modest announcement for the important changes in the text. After a thorough examination of the present edition, we can assert confidently that the enormous labor we have described has been here most faithfully and conscientiously performed. We take pleasure in repeating, that we believe this to be the best treatise on venereal diseases in the English language, and we congratulate the authors upon their brilliant additions to American medical literature.—*Amer. Journ. Med. Sci.*, January, 1880.

SMITH ON CHILDREN—New Edition—Just Ready.

LETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. By J. s **Smith**, M.D., Clinical Professor of Diseases of Children in the Bellevue Hospital al College, New York. Fourth edition, revised and enlarged. In one handsome volume of over 750 pages, with illustrations. Cloth, $4 50; leather, $5 50; half , $6.

riod which has elapsed since the third e work, so extensive have been the ad- whole chapters required to be rewritten, page could pass without some material addition. This labor has occupied the y, and he has performed it conscien- t the book may be considered a faithful f an exceptionally wide clinical expe- ntile diseases, corrected by a careful recent literature of the subject.—*Med. Reporter*, April 5, 1879.

The author has evidently determined that it shall not lose ground in the esteem of the profession for want of the latest knowledge on that important department of medicine. He has accordingly incorporated in the present edition the useful and practical results of the latest study and experience, both American and foreign, especially those bearing on therapeutics. Altogether the book has been greatly improved, while it has not been greatly increased in size.—*N. Y. Med. Journ.*, June, 1879.

FLINT'S CLINICAL MEDICINE—Just Ready.

L MEDICINE; A Systematic Treatise on the Diagnosis and Treatment of Diseases. ed for Students and Practitioners of Medicine. By **Austin Flint**, M.D., Professor Principles and Practice of Medicine and of Clinical Medicine in Bellevue Medical e, N. Y. In one large and handsome octavo volume of 795 pages; cloth, $4 50; ssia, $5.

sed to say that the author has accom- creditable manner the difficult task of t only a complete but a useful text- ern science. Its merits are many and lts, for a work of such range and di- w, and, with the exception of two or of questionable practice, criticized in and the present notice, comparatively e heartily congratulate the veteran completion of his undertaking, and strongly recommend his text-book as not only the most recent but the most complete hitherto published on clinical medicine.—*Dublin Journ. of Med. Science*, Jan. 1880.

Nothing but the most unbounded praise is equal to the merits of the book. At once in the introductory chapter we recognize the master's hand. It is most admirably written.—*Phila. Med. Times*, Feb. 28, 1880.

FLINT ON PERCUSSION—New Edition—Just Ready.

AL OF PERCUSSION AND AUSCULTATION; embracing the Physical Diagnosis ases of the Lungs and Heart, and of Thoracic Aneurism. By **Austin Flint**, M.D., sor of the Principles and Practice of Medicine in the Bellevue Hospital Medical e, New York. Second edition, thoroughly revised. In one handsome 12mo. volume pages. Cloth, $1 63.

THOMAS ON WOMEN—Lately Issued.

ICAL TREATISE ON THE DISEASES OF WOMEN. By **T. Gaillard Thomas**, Professor of Obstetrics in the College of Physicians and Surgeons, New York, etc. edition, enlarged and thoroughly revised. In one large and handsome 8vo. volume er 800 pages, with 191 illustrations. Cloth, $5; leather, $6.

DALTON'S PHYSIOLOGY—Lately Issued.

ISE ON HUMAN PHYSIOLOGY. Designed for the use of students and practi- s of medicine. By **J. C. Dalton**, M.D., Professor of Physiology in the College of icians and Surgeons, New York. Sixth edition, thoroughly enlarged and revised, 316 illustrations. In one very handsome 8vo. volume. Cloth, $5 50; leather, $6 50.

HENRY C. LEA'S SON & CO.—Philadelphia.

CORNIL & RANVIER'S PATHOLOGICAL HISTOLOGY—Just Ready.

MANUAL OF PATHOLOGICAL HISTOLOGY. By V. Cornil, Prof. in the Faculty
icine of Paris, and L. Ranvier, Prof. in the College of France. Translated, with
and Additions, by E. O. Shakespeare, M.D., Pathologist and Ophthalmic Surg
Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in U
Pa., and by Henry C. Simes, M.D., Demonstrator of Pathological Histology in the
of Pa. In one very handsome octavo volume of over 700 pages, with over 350 ill
tions. Cloth, $5 50; leather, $6 50; half Russia, $7.

The translators have done their work very well indeed, rendering it into smooth and excellent English, and in their selection of new material they have in the main used good discrimination. We heartily commend the book as one of the best works on the subject.—*Boston Med. and Surg. Journal,* March 11, 1880.

Their book is not a collection of the work of others, but has been written in the laboratory beside the microscope. It bears the marks of personal knowledge and investigation upon every page, controlled by and controlling the work of others . . . In short, its translation has made it the best work in pathology attainable in our language, one that every student, certainly, ought to have.—*Archives of Medicine,* April, 1880.

The high reputation justly accorded to the labors of Profs. Cornil and Ranvier throughout Europe is an ample justification of the translation offered to American readers by Drs Shakespeare and
This self-imposed duty has been carefully a
oughly executed, and well deserves that rec
which we sincerely hope will be granted.—
Practitioner, April, 1880.

This work, in the original, has for years
pied a prominent place in the library of
pathologists, as we should naturally be
lieve from the reputation of the distingui
thors. Now that it has been presented to
lish student for the first time, it will be pers
unusual interest. The illustrations are
means the least valuable part of the work.
pensable as they are to any work of this n
the work before us the artist has succeeded
ducing cuts which will prove unusually
to the reader. The translation is well d
gives evidence throughout the volume that
made by a person thoroughly conversant
subject.—*N. Y. Med. Gazette,* Feb. 28, 1880.

NETTLESHIP ON OPHTHALMIC MEDICINE—Just Ready.

A MANUAL OF OPHTHALMIC MEDICINE. By Edward Nettleship, F.R C.S., O
mic Surgeon and Lecturer on Ophthalmic Surgery at St. Thomas's Hospital, Lond
one royal 12mo. volume of over 350 pages, with 89 illustrations. Cloth, $2.

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr. Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences,* April, 1880.

A careful examination has convinced us
the best work of its class that has come to

memories by its careful study.—*Detro*
April, 1880.

MORRIS ON SKIN DISEASES—Just Ready.

SKIN DISEASES; INCLUDING THEIR DEFINITION, SYMPTOMS, DIAGNOSIS,
NOSIS, MORBID ANATOMY, AND TREATMENT. A Manual for Students an
tioners. By Malcolm Morris, M.D., Joint Lecturer on Dermatology at St.
Hospital Medical School. In one 12mo. volume of over 300 pages, with illus
Cloth, $1 75.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that, in the whole range of medical literature of a like scope, there is no book which for clearness of expression and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine,* April, 1880.

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct
and prescribe a rational treatment, we unh
recommend this little book of Dr Morris
fections of the skin are described in a t
manner, and their several characteristics
set forth that diagnosis will be easy. The
in each case is such as the experience o
eminent dermatologists advise.—*Cincin*
cal News, April, 1880.

GREENE'S MEDICAL CHEMISTRY—Just Ready.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students. Based upon B
Medical Chemistry. By William H. Greene, M.D., Demonstrator of Chemistry
ical Department University of Pennsylvania. In one royal 12mo. volume of 3
with illustrations. Cloth, $1 75.

It is well written, and gives the latest views on vital chemistry, a subject with which most physicians are not sufficiently familiar. To those who may wish to improve their knowledge in that direction, we can heartily recommend this work as being worthy of a careful perusal.—*Phila. Med. and Surg. Reporter,* April 24, 1880.

The little work before us is one which
will be studied with pleasure and profit
scriptions, though brief, are clear, and in
sufficient for the purpose. This book will,
all cases, meet general approval.—*Am.*
Pharmacy, April, 1880.

HENRY C. LEA'S SON & CO.—Philadelphia.

LEISHMAN'S MIDWIFERY—New Edition—Just Ready.

STEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE. By William Leishman, M.D., Regius Professor of Midwifery in the University of Glasgow, etc. Third American edition, revised by the author, with additions by John S. Parry, M.D., Obstetrician to the Philadelphia Hospital. In one large and very handsome 8vo. volume of 733 pages, with over 200 illustrations; cloth, $4 50; leather, $5 50; half Russia, $6.

works on this subject have met with as great and as this one appears to have To judge frequency with which its author's views are , and its statements referred to in obstetrical are, one would judge that there are few phy- devoting much attention to obstetrics who bout it. The author is evidently a man of perience and conservative views, and in no of medicine are these more valuable than in *New Remedies*, Jan. 1880.

ladly welcome the new edition of this excel- xt-book of midwifery. The former editions een most favorably received by the profes- both sides of the Atlantic. In the prepara- the present edition the author has made such one as the progress of obstetrical science to require, and we cannot but admire the with which the task has been performed. sider it an admirable text-book for students their attendance upon lectures, and have pleasure in recommending it. As an exponent midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

The book is greatly improved, and as such will be welcomed by those who are trying to keep posted in the rapid advances which are being made in the study of obstetrics.—*Boston Med. and Surg. Journ.*, Nov. 27, 1879.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings, and with demonstrations noted for clearness and precision, it will gain in favor, and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise. To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

PLAYFAIR'S MIDWIFERY—New Edition—Just Ready.

ATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY. By W. S. Play- , M D, F.R.C.P., Professor of Obstetric Medicine in King's College, etc. etc. Third erican edition, revised by the author. Edited, with additions, by Robert P. Harris, D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. h, $4; leather, $5; half Russia, $5 50.

Extract from the Author's Preface.

cond American edition of my work on Midwifery being exhausted before the corre- English edition, I cannot better show my appreciation of the kind reception my book ved in the United States than by acceding to the publisher's request that I should ndertake the issue of a third edition. As little more than a year has elapsed since d edition was issued, there are naturally not many changes to make, but I have, less, subjected the entire work to careful revision, and introduced into it a notice of the more important recent additions to obstetric science. To the operation of gastro- my—formerly described along with the Cæsarean section—I have now devoted a sepa- apter. The editor of the second American edition, Dr. Harris, enriched it with many notes, of which, it will be observed, I have freely availed myself.

dical profession has now the opportunity to their stock of standard medical works best volumes on midwifery ever published. ct is taken up with a master hand. The ted to labor in all its various presentations, gement and results, is admirably arranged, views entertained will be found essentially and the opinions expressed trustworthy. abounds with plates, illustrating various positions; they are admirably wrought, great assistance to the student.—*N. O. Surg. Journ.*, March, 1880.

ed of by a medical student what work on we should recommend for him, as *par* , we would undoubtedly advise him to layfair's. It is of convenient size, but what f importance, its treatment of the various is concise and plain. While the discussions riptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880.

It certainly is an admirable exposition of the Science and Pathology of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880.

DUNCAN'S CLINICAL LECTURES ON DISEASES OF WOMEN—Just Ready.

CAL LECTURES ON THE DISEASES OF WOMEN. Delivered in St. Bartholo- w's Hospital. By J. Matthews Duncan, M.D., LL.D., F.R.S.E., etc. In one very neat avo volume of 175 pages; cloth, $1 50.

are in every way worthy of their author; we look upon them as among the most valu- ble contributions. They are all upon mat- great interest to the general practitioner. them deal with subjects that are not, as a quately handled in the text-books; others , while bearing upon topics that are usually of at length in such works, yet bear such a f individuality that, if widely read, as they ly deserve to be, they cannot fail to exert a ome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journal*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

HENRY C. LEA'S SON & CO.—Philadelphia.

THE NATIONAL DISPENSATORY—Second Edition—Just Ready.

THE NATIONAL DISPENSATORY; CONTAINING THE NATURAL HISTORY, CHEMISTRY, PHARMACY, ACTIONS AND USES OF MEDICINES, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. By ALFRED STILLÉ, M.D., LL.D., Prof. of Theory and Practice of Medicine and of Clinical Med. in the Univ. of Pennsylvania, and JOHN M. MAISCH, Ph.D., Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of sixteen hundred and ninety-two pages, with two hundred and thirty-nine illustrations; extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Journ. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a second edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Med. Journ.*, Nov. 1879.

A new edition of this great work, only a few months after the first, takes us by surprise. It indicates the high appreciation of its value on the part of physicians and pharmacists, by which a large edition has been so soon exhausted. The present is not merely a reprint but a revision, with important additions and modifications, requiring 100 pages of new matter, and an index increased by 2250 references. The doses are stated in both the ordinary and metric terms. All the more important material of the German and French Pharmacopœias is embodied. It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Jour.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory. —*Canada Med. and Surg. Journ.*, Feb. 1880.

BRISTOWE'S PRACTICE—New Edition—Just Ready.

A TREATISE ON THE PRACTICE OF MEDICINE. By JOHN SYER BRISTOWE, M.D., F.R.C.P., Physician and Joint Lecturer on Medicine, St. Thomas's Hospital. Second American edition, revised by the Author. Edited, with additions, by JAMES H. HUTCHINSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half Russia, $6 50.

In reprinting this work from the recent thoroughly revised second English edition, the author has made such corrections as seemed advisable, and has added a chapter on Insanity. The Editor has likewise revised his additions in the light of the latest experience, and the work is presented as reflecting in every way the most modern aspect of medical science, and as fully entitled to maintain the distinguished position accorded to it on both sides of the Atlantic as an authoritative guide for the student, and a complete though concise book of reference for the practitioner. Notwithstanding the author's earnest effort at compression, the additions have amounted to about one-tenth of the previous edition; but by the use of an enlarged page these have been accommodated without increasing the size of the volume, while a reduction in the price renders it one of the cheapest works accessible to the profession.

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science. The chapter on diseases of the skin and of the nervous system, with a new one on insanity compiled from the best sources outside of the author's own long experience, and the valuable portion relating to general pathology, aid greatly in completing an exceptionally good book for purposes of reference and instruction.—*British Medical and Surgical Journal*, February, 1880.

The popularity of the work depends, no doubt, upon the clear and incisive way in which it is written, and the attention to details likely to occur in practice, rather than the discussion of questions of theory.—*New Remedies*, Jan. 1880.

What we said of the first edition, we can, with increased emphasis, repeat concerning this: "Every page is characterized by the utterances of a thoughtful man. What has been said, has been well said, and the book is a fair reflex of all that is *certainly known* on the subjects considered.—*Ohio Med. Recorder*, Jan. 7, 1880.

This is not only one of the latest and most comprehensive works out on the general subject of Theory and Practice of Medicine, but it is unquestionably one of the best.—*So. Med. Practitioner*. Jan. 1880.

CLINICS.

Clinical Lectures.

SOME DISORDERS DEPENDENT UPON GENITAL IRRITATION; PROPER TREATMENT OF TALIPES, ETC.

AN ABSTRACT OF A CLINICAL LECTURE DELIVERED AT BELLEVUE HOSPITAL.

By LEWIS A. SAYRE, M.D.,
SOR OF ORTHOPÆDIC SURGERY IN BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK, ETC.

[Reported by F. Gundrum, M.D., and revised by the Author.]

ASE I.—The first case I have to show you to-day is one of loss of co-ation and spastic contraction of the lower extremities, with strongly ed talipes equino-varus in both feet.

e mother gives the following history : The patient's name is Anna, she is ten years of age. She seemed to be normally developed at , though the mother thinks the lower extremities were not propor-tely well developed with the trunk. Three months after birth an ab-s began to develop in the neck. It was finally opened and emptied of ontents. It continued to discharge pus for a long time. She also had difficulty of vision, but the cause is not very clear. Her health me very delicate and remained so for several years. When she was t thirteen months of age she made some efforts at creeping, and at and a half years she began to walk some, which was, however, very rfectly and awkwardly done. As she continued to make efforts at king, her knees began to give way and she became quite "knock-ed." She also no longer put the whole plantar surfaces on the floor, gradually began to walk "on her toes." In this awkward condition continued to get around in the room by the aid of assistants, chairs, beds, until five years of age, when she met with a serious accident. fell a distance of thirty feet, through a skylight. Although no ap-ent serious damage had been sustained, the child made no more efforts locomotion for nearly two years. Many efforts have been made by geons and at some of the orthopædic institutions of this city to correct deformities, but with no success worth speaking about.

She is able, by the aid of assistants, to move small distances, or sta up while holding to a chair, and when she does so she stands on "ti toe," and her knees are tightly pressed together. The mother sta that she has been annoyed, constantly, from her birth to the present ti by thread worms (oxyuris vermicularis), making her existence alm unbearable. They accumulate in the rectum in great numbers. Th torture her so that the mother has to use enemas, or extract them wi her finger. They not only produce great irritation in the rectum, b voluntarily leave that abode and get on the verge of the anus and into t genital tract. The little girl has always suffered from genital irritati She desires to urinate often, and suffers considerable pain during the a She puts her hands to her genitals frequently, but the mother is positi that it is for no vicious purpose.

About three years ago her general health began to improve, and h continued to do so until now, when we find her a well-nourished girl average size. About four weeks ago a leucorrhœal discharge was notic which continued to increase for three weeks, at which time blood w mixed with it. Both discharges, however, have ceased. The mot thinks the child is somewhat backward intellectually. As you now serve she is unable to stand alone. When we ask her to move the lo extremities she makes many efforts before she succeeds, and then o slightly raises the thigh. When she endeavours to walk the limbs moved altogether at the hip, while the thighs are strongly adducted, as she brings one limb in front of the other, it crosses in front of its fel When the other is brought forward, it strikes the opposite limb beh The upper extremities also lack in the co-ordinating power, as you the movements of her arms are slow, halting, and uncertain. She h peculiar unintelligent, silly look. We are unable to fix her attentio anything long at a time. She soon gets out of patience, cries, the next moment bursts out into a laugh—laughs while the tears trickle down her cheeks—showing in a very marked degree what is kn as hysteria. Having bared her lower extremities, you will observe her limbs are of good size, the thighs slightly flexed, and strongly ducted, and the legs are flexed on the thighs. The feet are in extr extension, forming talipes equinus. Anterior to the mediotarsal jo the feet are turned inwards, forming the deformity to which we apply name of varus.

When I come to examine the plantar surfaces I find the arch deep and shortened, and the fascia very tense. So here there is a double formity, an equinus and varus. When two deviations occur in the fo the same time, the names are associated, prefixing that one which re sents the greater deformity; so in this case, the equinus being the gre the deformity is called talipes equino-varus.

The deformity is much more marked in the right foot, and you notice this hard projection in front of the tibia, which is the scaphoid luxated. If I ask the child to separate her thighs, she makes some e but fails to get control of her muscles. By taking hold of the knees making an effort to separate them for her, I find it takes considerable fo gradually applied, to make abduction to any extent, the muscles be rigid and unyielding. I find the muscles of both lower extremities in same condition. Having flexed the leg upon the thigh at an angl about 45°, so as to relax the extensors of the foot, I will see how near foot can be restored into its normal position. As you see, by great f adually applied, I am enabled to bring the foot at right angles with the g, or nearly so. By increasing the flexion of the leg, so as to relax the strocnemius and soleus as much as possible, I can carry the extension the foot still a little farther. I have continued this now as far as pos- le. You will now ask the question, and justly so, if the extensors can stretched thus far, why not farther—gradually, until they allow the t to assume its shape, and the deformity is cured.

This question is easily decided by the following test. Having carried ension as far as possible, I have put the tendo-Achillis tightly upon the tch. While holding it in that position, I take my thumb and make itional pressure on it, and, if under this additional tension there is no ex spasm, you can stretch it still further, and a cure may and can be cted without tenotomy; but, if, on the contrary, that additional press- produces reflex spasm at the time, tenotomy must be performed, as can never cure your case without it. You see the additional tension uces immediately a reflex spasm, and therefore we shall perform tomy. In bringing both tendo-Achilles under this test, also the tar fasciæ, we find that they give the reflex spasms, and must be di- d. When you obtain this test, you may know structural change has place, and no amount of tension, however applied, will ever restore arts into their normal position.

e assistant will now proceed to give the child chloroform, but before so I will see that her clothing is not constricting her neck, chest, or . This is a very important point to look after before the adminis- n of an anæsthetic, and I advise you to never neglect it when you e to practise your profession.

ow show you the instrument I shall use to divide these tendons and e—my tenotome. The instruments you will find for sale in most of stablishments are a sharp-pointed straight knife. Never use one of under any consideration. They are dangerous.

e next objection is that they have a straight cutting edge. This ment you see has a convex cutting edge and a concave strong . It is very narrow, not exceeding a line, and has a broad convex . Here is an instrument that claims to be an exact counterpart of , but you see the blade is twice as wide. I have never met with an ent in dividing the muscles, tendons, and fasciæ, and I attribute no to the instrument I use. If you use a sharp-pointed tenotome, if a l or nerve comes before it, you are certain to puncture it, but with rounded point, which is not very sharp, such tissues will slip away e it.

e patient having become completely narcotized, I shall proceed with operation.

urning the patient over on her side, so as to turn the plantar surface ards, I have the fascia put tightly on the stretch by an assistant grasping front part of the foot, and, making strong extension, I search for the r border of the plantar fascia, and, having found it, I introduce the teno- e flatwise through the skin, and now I am able to feel the inner border e fascia with the point of my knife. I gradually sink my instrument l I feel I am under the fascia. Then I pass the knife horizontally r it until I have reached the other side. I now turn the cutting edge e instrument upward against the fascia, and my thumb is placed over I press the fascia on the knife, at the same time giving the latter a tle to-and-fro motion until all the contractured tissues are divided. I turn the knife on the flat again and withdraw it, and as I do so I follow with my thumb and squeeze out what blood there may be in the wound a guard against the ingress of air. On removing my thumb I apply a pi of adhesive plaster quickly, so as to hermetically seal the wound, over th I place some cotton wool, and secure both with a roller. The assist now renders the tendo-Achillis tense by forcibly extending the foot, wh I divide the latter just as I did the plantar fascia. After having divid hermetically sealed, and applied the cotton and roller, as above describ the whole foot, excepting toes, is enveloped in cotton wool, to guard agai injurious compression, and a roller is applied over the foot and ankle about five or six inches above the latter. An extra thickness of cot should be applied to the sole of the foot.

I now bring the foot straight on into its normal position, which you s the foot being at right angles with the leg, and as I cannot sit here a hold it until the result of the operation shall be repaired, I shall endeav to accomplish the same end by the following dressing: Take a thin boa such as a shingle or the lid of a cigar box, and cut it so that it shall about a quarter of an inch wider, and about three inches longer than foot, modelling it after the shape of the latter. Then take a strip of hesive plaster about two and a half inches wide, and of sufficient lengt surround the foot board, and reach above the knee. Now take the b into your hand, the heel towards you, and wind the adhesive plaster aro it lengthwise, commencing within an inch or two of the front of the b on the under surface (the adhesive side being next to the board). B it forward over toe end, back over the heel end, and then forward on under side to the front, catching the end where you started. After ha wrapped the board in this manner, your adhesive plaster should sti sufficiently long to reach half way up the thigh.

Take another strip of adhesive plaster from one to two feet long, o to the size of the foot, and an inch or two wide, and fasten it about middle to the heel of the board, in such a manner, that about half width of the plaster will catch the under surface of the heel of the bo I do this in order to get a good hold so that it cannot slip off. Now a a thick layer of cotton on the board that is to go next to the foot and a a roller pretty firmly, so as to prevent the cotton from slipping. always should be done, so as to thoroughly protect the bottom of the from pressure. In many of these cases the tissues about the feet are tremely insensible to irritants, and having a low vitality extensive slo ing might be the result from applying the board if not well cushioned.

Now apply the cushioned surface of the board to the sole of the allowing the heel of the board to project an inch beyond that of the While holding the foot at right angles with the leg, and the board fi against the bottom of the foot, take one end of the plaster fastened to heel of the board, bring it forward across the dorsum of foot to the opp side of the foot from where you started, and pass it over the edge of the b to the under surface, where you fasten it. Then take the other end of same plaster and follow the same movements, except that you carry the opposite side. After having completed this sandal-like fastening take a roller and firmly secure the "foot-piece" to the foot. Should foot have a tendency to turn in or out, an extra strip of adhesive pl becomes necessary.

In this child, you see, the foot is inclined to turn inwards, and, there I shall take this strip of plaster, which is about one and a half inch nd a foot and a half long, start with one end on the outer side and front rt of the foot, pass it across the dorsum toward the inner border under e foot and bring it to the outer edge and secure it with a few turns of a ller. The wide strip of adhesive plaster at the front of the board is now rried up the leg to the knee, or, where a good hold can be obtained, as in ry little children, half way up the thigh. The guy is now carried up on e outer or inner side of the leg, as the case may be, and tension applied til the lateral deviation is corrected. The strip carried up the front is plied to the leg, while the foot is at right angles—both are secured to leg by a roller. The extra lengths of the plasters are reversed, which ses the dressing to remain in place longer. One caution is necessary applying this dressing, viz., *that you leave the toes exposed so you can ays keep watch of the circulation.*

Having completed the dressing of this, the right foot, I shall proceed to left one, where I shall divide the same tissues and apply a similar sing.

ou see both feet dressed, and perfectly straight. Were I now to put child in the erect posture she could stand squarely on the soles of her . This is a simple, inexpensive dressing, obtainable anywhere, and effectiveness is superior to any or all the dressings I know anything t.

rmerly surgeons did not treat their cases as we have this one to-day. r to the correction of the deformity *immediately* after the sections. s the practice, and I am exceedingly sorry to say is to a great extent to allow the foot to remain in its deformed position for a number of , until the external wound has cicatrized, and the division of the ten- repaired to a slight degree. As soon as the surgeon thought that nous material had been thrown out between the ends of the tendons began to organize, he then, and not until then, could commence to ct the deformity. He commenced to apply traction, in order to ch this new material that nature was throwing out between the ends e tendon. This he was to continue until he had cured the deformity. ve followed this plan myself years ago, but it was tedious, caused the nt untold misery, and seldom succeeded. In the few cases where it cceed in correcting a deformity, the stretched tendon was too feeble ve proper support.

eeting with so much difficulty with this method of treatment, and the nent good accomplished being so seldom satisfactory, I finally con- d to abandon it. I determined to restore the parts immediately after rming tenotomy, being certain the result could not be much worse if ivided ends never united than where the union was so feeble. But y great surprise and satisfaction I discovered that, after ten to twelve , the patient could move his foot by bringing into action the muscle hich tendon had been severed—clearly showing that union was possible e the divided ends were separated. Since then I have abandoned the or the new method, and after many years of a large field of experience, onounce the latter method as the proper one.

his is to me an extremely interesting case. I have shown you several during the last winter in my clinic, very similar to this, in male dren due to congenital phimosis. In them, as in this little girl, there loss of co-ordination, and paresis and rigidity of the muscular tissue he lower extremities, the nervous system exhausted, and the mind ch impaired, amounting in one case to an idiotic condition. In none

of our cases, however, have we noticed the hysterical condition that
see in this little girl. What is the condition of this little girl due to?
believe it to be due to genital irritation, and I also believe that the so
of irritation has been the presence of the oxyuris in the genital tract.

The future treatment of this patient will be to remove the sour
irritation of the genital organs by destroying, if possible, the par
which produces it, and to restore muscular power.

I shall leave on this dressing for eight or ten days, and then remov
when I shall expect to see all the incisions firmly united. The feet
then be redressed for a week or two longer, until the tendons and fa
have firmly united. I shall then maintain the feet in proper positio
the aid of properly fitting shoes, and elastic force if necessary, while I
store the muscles to a healthy condition by the use of massage, pro
directed gymnastic exercise, electricity, etc. etc.

Cases II. and III.—I have next to show you a pair of male tw
The mother brought them to my office some two weeks ago to consul
in regard to a hernia, which had been developed in each since their b
I found an inguinal hernia in each on the same side. While exami
the hernia of the first child I discovered that the penis was unu
large, and in a state of semi-erection. On questioning the mothe
stated that the penis was in erection a great deal of the time; th
children cried a great deal; that when they urinated they straine
hard, and screamed as though they were suffering extremely. Both
in the same condition. On closer examination the opening in the pr
was found extremely small, and it was with great difficulty that the
of the urethra could be seen. The latter was very red and angry
ing, and on being touched a spasm of the lower extremities fol
Behind the corona glandis there was noticed a large, hard swelling.

There is not the least doubt in my mind, gentlemen, but that th
nia is a result of the phimosis. The very small opening in the pr
which prevented a free discharge of urine, and the extremely ir
condition of the mouth of the urethra, causing excruciating suffering
time urine passed over it, were the cause of the crying and stra
which brought on the hernia.

I consider it for these children extremely fortunate that this g
irritation has been discovered so early—before it has had time to ser
enervate the nervous system with all its evil consequences. In or
prevent any further ill effects on the system, it will be necessary t
the glans penis in each one by an operation.

I will now perform the operation of circumcision. I catch hold o
end of the prepuce with my fingers and draw it forward. I now pl
pair of Henry's forceps in front of the glans, grasping the pre
When I have drawn through the amount of prepuce I wish to exc
firmly close the blades of the forceps, and lock them. Having don
I take a sharp bistoury and cut off the prepuce in front of the blades o
forceps. I now unlock the forceps, and free the prepuce. As you ca
see, I have cut off the outside skin only, the mucous membrane re
ing. I have not enlarged the opening in the prepuce in the least, and
glans is as much imprisoned as before.

I have seen several cases where the surgeon, when he had gone
far, thought he had completed the operation. Only a few days ago a
eight years old, was brought to me from Florida where this was the
After many months cicatrization took place, and left the child worse

e was before. The cicatricial tissue had contracted, and was hard and nyielding. To avoid any such bad consequences you now see me pass is small grooved director into the preputial opening in front up to e glans. You see I do this with considerable difficulty, owing to the glutination of the prepuce and glans. I am unable to carry the direc- r entirely up to the corona, consequently I shall divide the mucous embrane as far as the director has been passed. Having done this I w separate the mucous membrane from the glans, by tearing it loose, ith my thumb and fingers.

Having entirely separated the glans and prepuce, you see, the corona is ry red, and behind it I find hardened, gritty smegma. Having com- eted the operation thus far, I want next to call your attention to an tremely important part of this procedure, viz., the frænum. This you ll usually find very short, with pockets on either side.

Never consider your operation completed until you have broken down s shortened band of mucous membrane. Should you neglect it your ration will, in all probability, remain without any benefit to the patient. ving broken down the band of mucous membrane, the frænum, see t neither it nor the outside skin in any way constricts the penis—*if re are any constricting bands they must be divided.* The operation g completed I shall dress it as follows: In very small children I sel- use sutures, but bring the cut edges of the skin and mucous mem- e accurately together, behind the glans, and then take a soft piece of linen cloth, or lint, and wrap around the penis over the coaptated cut es. I allow the meshes of the cloth to become saturated with blood, if hemorrhage does not cease I apply over this some styptic cotton. n I form a circular pad, with a hole through the centre, into which penis is placed and allowed to remain, excepting when the dressings renewed, until cicatrization is complete. A pledget of lint dipped into er is placed over the glans, and the whole retained in place by a er. This dressing will remain on for five or six days, when I shall ect union to have taken place.

There is one thing I want to caution you against, and that is, if cicatri- ion should be delayed, to guard against subsequent adhesion of the pre- e to the glans, or the formation of cicatricial bands. Many a surgeon met with failures by not observing this precaution.

Note. May 1, 1880.—The first case, that of the little girl, has improved ond all expectation. The dressings of both feet were removed on the th day, and very fortunate it was. Although the feet were protected n pressure by thick layers of cotton-wool, if the dressing had been wed to remain on a few days longer extensive sloughing on the instep ld have been certain. As it was, only superficial destruction of the n over a small area took place. The same dressing was reapplied, and nged once in two or three days for three weeks. Properly-fitting es were then applied (ordinary shoes made to fit the child), which re- ned the feet in proper position without any elastic force. Since then e has had electricity applied every other day, and the muscles of the ghs and legs have been manipulated daily, the peronei receiving especial tention. The general health has been improved by proper dieting and nty of outdoor exercise. The patient has received daily training in e use of her muscles, and especial effort has been exerted to "hitch her ain to her muscles"—to improve her will-power, and inspire confidence n her own capabilities.

She is now able to abduct her thighs to their fullest capacity—
limbs are perfectly straight. They have increased in size and streng
She is now able to walk alone across the room. When the feet are bar
they can be held perfectly straight; she can extend and flex them v
nearly perfectly. When they are carried to extreme extension, the f
turn slightly inwards, showing a deficiency of power in the pero
muscles. F. G

ON THE "SUMMER COMPLAINT" OF INFANTS.

A CLINICAL LECTURE.

By J. LEWIS SMITH, M.D.,
CLINICAL PROFESSOR OF DISEASES OF CHILDREN IN THE BELLEVUE HOSPITAL MEDICAL
COLLEGE, NEW YORK.

GENTLEMEN: The hot weather is now approaching, during which
most prevalent and fatal disease of the cities is the so-called "summer c
plaint" of infants. It is especially fatal in the large cities of the Atl
coast. It is an intestinal catarrh, which begins to appear in the mi
and latter part of May, and becomes more and more frequent, reachin
maximum prevalence and severity in mid-summer, after which new c
are less and less frequent till the last of October, when the epide
gradually disappears, and no cases remain except such as have ling
from the hot months.

The "summer complaint" is, anatomically, a catarrh of the lower
of the small intestine, and of the entire large intestine: the inflam
tory lesions being, in fatal cases, most marked in the descending por
of the colon, and especially in the sigmoid flexure, where the excre
titious matter is most apt to be delayed and to accumulate. The gre
thickening and redness of the mucous membrane in this locality, whi
have often observed at autopsies, has seemed to me chiefly due to
irritating nature of the fecal matter, just as the erythematous redne
the skin around the anus present in certain cases, arises from this ca
The ulcerations which are apt to occur in grave protracted cases,
which are circular and seem to correspond in site with the soli
glands, are also most numerous in the descending colon, and particul
in the sigmoid flexure. Most cases of this disease occur prior to the
of two and a half years; so that the "summer complaint" is al
peculiar to infancy. But the first years of childhood are not enti
exempt.

There are two important factors in the causation of the "summer c
plaint:" 1st. The atmospheric heat, which acts as a causative agent, no
much by its direct effect on the system—though its direct enervating
fluence may act to a certain extent, as a cause, by impairing the gen
tone of the system, and the digestive function in particular—as by p
ducing foul gaseous exhalations from the decaying organic matter, wh
always exists in considerable quantity in and around the crowded domic
of the poor in our cities. Abundant observations show that the "sum
complaint" is most frequent and fatal in those localities, where the stre
court-yards, and apartments are most filthy. In these places the f
odours are often very perceptible to the visitor. The operation of t

cause seems to me to be similar to the foul air of the dissecting-room, in former times, when the medical student remaining long at dissection was apt to be incommoded by attacks of diarrhœa.

2d. The other cause is not less important, and in a large proportion of ses its action is apparent. It is the use of unsuitable food. For food which the feeble digestion of the infant cannot assimilate, soon begins to ndergo fermentative changes, and acts as an irritant and purgative. It s the common opinion among families that the "summer complaint" is ost frequent and dangerous in the second summer, but many observa-ons establish the fact, that the first summer possesses no immunity, but n the other hand, the younger the infant, the greater the liability to be ttacked if the diet is improper, and the reason why so many infants re-ain well in the first summer is that they are nourished at the breast, d this second factor or cause is not operative in them.

It is not my intention at this time to speak at length of measures de-gned to prevent the "summer complaint," or of the hygienic measures quired in its treatment, except to state certain facts, which are very im-rtant, and the knowledge of which will materially assist the physician o has had little experience with the disease. First, every infant under age of twelve months in the city should, if possible, have the breast k during the hot season. If the mother be not competent to furnish it, et-nurse should be employed. If it cannot have the breast milk, the ily should be urged to go to the country, especially during July and gust. Never consent to the weaning of an infant in or just before the weather. Statistics which I have preserved, bearing on this point, w a most disastrous consequence. The new diet will not agree, and if ning be necessary, insist on removal to the country.

But there is a large number of infants in the families of the city poor that weaned at this improper time, no physician having been consulted, and rge number also who are wet-nursed, but the breast milk is insuffi-t, and it is necessary to employ more or less artificial food. Now it ery important to decide what kind of food should be given. The shops tain several so-called "substitutes" for breast milk, but the milk of the or goat more closely resembles human milk, than do any of these bstitutes," and when sufficiently fresh, and of good quality, it is to be ferred, I think, for most infants. For an infant under the age of two nths it should be diluted with one-third its quantity of water; for e between the ages of two and five months, one-fourth or one-fifth its ntity of water should be added; while for those over the age of five nths, no dilution is ordinarily required. The infant after the age of month should not take the breast more frequently than every second r, and for artificial feeding it is well to have a little longer interval.

The caseum of cow's or goat's milk is apt to coagulate in the stomach the young infant in large masses, which are with difficulty digested. aid, in a measure, in preventing this a thin farinaceous food, as barley-ter, or rice-water well boiled, may be mixed with the milk. The fari-ceous particles intimately mixed with the caseum tend mechanically prevent the coagulation in large masses. In an infant now under ob-vation in the New York Infant Asylum, cow's milk given in the dinary way caused vomiting, but, by preparing from it a wine whey, th a small proportion of sherry wine by which a considerable part of the eum is removed, it is no longer troubled with indigestion and is doing ell. The employment of fresh wine whey, thus prepared, will often be found useful, at least as a temporary expedient, when the infant vo milk prepared in the ordinary manner, and containing the full amount casein. It has been proposed by Drs. Rudisch and Jacobi of this city coagulate the casein, or at least a part of it, by hydrochloric acid be the milk is used. A half teaspoonful of the dilute officinal acid is added one pint of cold water, and this is thoroughly mixed with two pints of c milk, and the mixture is then boiled ten or fifteen minutes. This has b employed for only one infant under my observation, in one of the insti tions. It had vomited the cow's milk previously given, and it vomi this as well. I design, however, to give the acidulated milk a more tended trial in the approaching hot season.

Another way of getting rid of a considerable part of the casein, wh I have for many years employed, is to allow the milk, as soon as recei to stand for two or three hours, when the casein, from its greater spec gravity, has a tendency to fall, and the cream to rise. The upper port can then be removed for use. If, as I think is ordinarily the case, gives too much butter, the superficial layer of cream can be separated rejected.

Still, there are many infants during the summer months, with wh cow's milk prepared in the usual way does not agree, and will not be li to agree, however prepared, and condensed milk is found to do no be For such, a thin gruel made from barley, rice, or wheat flour (the having by preference been boiled in a dry state, several hours in a and then grated) should be mixed with the milk in equal quantity, or gruel may be in excess. By such aids we do the best we can to assist feeble digestive function of the infant, but nothing which we can pr will take the place of human milk for those under the age of twelve mo Of the various kinds of infants' food found in the shops, Ridge's food, pared with milk, and Nestle's lacteous farina, prepared with water, been favourably received, and many infants do well upon them excep the hottest weather. The medical profession will always regard kindly feelings, the earnest endeavour of the renowned chemist, B Liebig, in the last years of his life to prepare a substitute for human m so important did he consider the subject of infant diet. Physiolog that time taught that young infants could digest only a very small qua of starch, since in the first months of life the amount of salivary secr by which starch is converted into glucose, a necessary change in digest is inconsiderable. But now it is ascertained that there is an epith ferment, which effects this change as well as the saliva. As Prof. F Jr., says " . . . the intestinal juice of itself is capable of effecting transformation of starch into sugar to a considerable extent," and epithelial ferment in the buccal cavity appears to act in the same (Richet). Therefore it seems that the youngest infant can digest a m rate amount of starch, though farinaceous substances are not to be pended on as a chief article of diet for any infant under the age of fou five months.

But the theory that starchy food could not be digested, or is diges slowly and insufficiently by such infants led Liebig to the preparatio his food in which starch is converted into glucose by the action of m Now I have used quite extensively the three preparations of Liebig's f contained in the shops, namely Hawley's, Horlich's and Mellin's, although they do well, answering the purpose for which they were desig in the spring, autumnal, and winter months, I have discarded their us the summer season. If employed, except in small quantity, they certainly produce a laxative effect, from the large quantity of grape sugar which they contain, during those months when there is special liability to diarrhœal attacks. With these preliminary remarks, I wish to speak more particularly of the medicinal treatment of the summer complaint.

While it is very important that this disease should receive early treatment, unfortunately many cases are allowed to run on for days or even weeks before the physician is called. This neglect I find to be due in many instances to the belief common in the community, that a relaxed state of the bowels renders dentition less dangerous and is a relief to it, so that the infant may have half a dozen alvine discharges each day, and the parents believe that they are salutary, till finally they are alarmed by the evident loss of flesh and strength.

As in many other maladies, the medicinal treatment has materially hanged within the last few years. Calomel, formerly administered in mall doses in the belief that the function of the liver needed rectifying,—his belief arising from the fact that the stools are green in many cases—as been discarded. The green colour is now known to be produced in e intestines at a considerable distance below the point where the bile ters it, and to be the result apparently of the admixture of the intesti-l secretions with the fecal matter, just as the stools sometimes have the rmal colour when evacuated and become green from the action of the ine. The old dread of administering opiates to infants, promoted in is country by the perusal of Beck's "Infant Therapeutics," has ceased, consequence of accumulated observations, showing their good effects, d the little risk which attends their judicious employment. The vege-ble astringents, such as kino, catechu, and tannin, are now little used; other agent which is more readily administered, less likely to cause usea and is more effectual, taking their place.

Occasionally it is proper to commence treatment by the administration a gentle purgative, as a single dose of castor oil, or a mixture of syrup rhubarb and castor oil, when there is reason to think that the diarrhœa s been excited or aggravated by some irritating substance which the fant has swallowed, and which should be expelled before measures to strain the stools are employed; but ordinarily no such preliminary treat-ent is required, as the diarrhœa has continued so long when the physi-n is called that any fruits or other substances injudiciously given must ready have been expelled, or the history of the case shows that no such bstance has been taken.

Our main reliance must be on opium and bismuth subnitrate, for the rpose of checking the stools, and arresting the catarrh, and, as fermenta-ive changes in the milk usually cause an excess of acids in the intestines, n some alkali, as the preparations of chalk. Opium is as useful in check-g the intestinal catarrh of infants as it is in that of adults, but I seldom give it or other medicine in the form of powder, experience having taught me that powders are apt to be partly wasted.

For infants under the age of five months opium may be safely and conveniently administered in paregoric, in doses of three drops to an infant of one month, five drops to one of three months, and eight drops to one of five months. For an infant of six months the deodorized tincture of opium should be given in half-drop doses, and for one of twelve months in drop doses. The interval between doses should be about three hours. Opium should never be prescribed in those advanced or grave cases in which there is marked drowsiness, or rolling of the head due to incipient spurious hydrocephalus. Refraining from its use for such patients, an giving it in the doses and with the interval stated above, I have alm never had occasion to regret its employment, though prescribing it sever times each day during the hot weather, in private and asylum practic Drops are of very variable size when falling from the mouth of a bot and the dropper should always be employed, so that the drop may be nearly as possible half a minim. The metric system insures more exac ness, but we are not yet ready for it in this country. In certain seve cases the opiate may be given for a time every two hours.

The bismuth subnitrate is applicable to all cases, possessing no disa vantages, and producing no ill effects to limit its use. It may be giv safely and with advantage in all stages of the malady as long as there vomiting or diarrhœa. It is an efficient anti-emetic and antiseptic. seems to act mainly locally, restraining the stools, increasing their consi ence, and producing a soothing and curative effect upon the inflamed su face. It probably retards fermentative changes. It becomes a bismu sulphide as dark as charcoal in the stomach, as I have observed autopsies, and if taken in large doses, as it should be, it renders the sto dark. It sometimes taints the breath like that from onions or garlic, bu am informed that this is probably due to some impurity. It has long be in use in practice, but in insufficient and inadequate doses, for infants, u within recent years. An infant of one year should take it in doses of or twelve grains, and one of six months in six or eight grains.

Although we do not wish to produce alkalinity within the stomach, as pepsin in its normal state is acid, and necessarily so for healthy digesti yet in the "summer complaint" there is an undue development of aci probably mainly the lactic. Therefore alkalies, as lime-water and the parations of chalk, have been long used in this disease, and with appar benefit, especially in the more acute cases. Alcohol, in moderate quanti aids digestion, and is a heart stimulant. It is quickly eliminated fr the system of the infant, and should be given at intervals of one to t hours to those who require it. It is given best in the form of Bourb whiskey, brandy, or sherry, port, or Madeira wine. It is urgently manded when, from failing heart action, hypostatic congestion of the lu or brain is occurring or impending. In spurious hydrocephalus, whi complicates many severe and protracted cases, its timely use aids mater ally in averting the danger. Many years ago Dr. Gooch, of London, w in the habit of employing in such cases of failing heart action the aromat spirits of ammonia, and in five-drop doses sufficiently diluted in water is a good stimulant and antacid.

Mild cases do not require special treatment designed to reduce tempera ture, as it is but moderately elevated. If the heat of head be moderate increased, a cloth wrung out of cold water should be constantly applied t it, and especially should the nurse be forbidden to cover the head excep in the lightest and coolest manner, either in the house or out-door. I those severe cases known as choleriform diarrhœa, or cholera infantum more energetic anti-pyretic local treatment is required. This form of intestinal catarrh, which usually occurs quite abruptly, having been preceded either by a state of health, or a mild diarrhœa, and is characterized by frequent watery stools and rapid loss of flesh and strength, is attended by a temperature unusually high, namely from 104° to 106°, o even higher. Such great elevation of temperature involves danger, and the prompt use of measures designed to reduce it constitutes an importan part of the treatment. A bladder containing ice may be applied to the calp, separated from it by one or two thicknesses of muslin, and the ex- essive heat of the hands and arms may be reduced by frequent sponging ith cool water, and clysters of iced starch-water or mucilage are proper.

To these general observations in reference to the selection and use of erapeutic agents, it may be useful to the young practitioner to add cer- in formulæ, which, or the equivalents of which, experience has shown to useful. To control the diarrhœa the following should be prescribed an infant of one year: ℞. Tinct. opii deodorat. gtt. xvj; Bismuth. bnitrat. ʒij; Syr. simplic. ℥ss; Mistur. cretæ, ℥iss. Misce. Shake bot- and give one teaspoonful every 3 hours. An infant of six months can e half the dose. A powder of bismuth, with the compound powder of lk and opium, or with Dover's powder, has a similar effect.

Vomiting is often a very troublesome symptom, but the bismuth in the ove prescription not unfrequently checks it. Its cause is probably not ays the same. It is sometimes relieved by lime-water and brandy in k when due to an excess of acid in the stomach, but the following pre- iption has given me more satisfaction than any other: ℞. Vini ipecac- hæ, gtt. ij; Bismuth. subnitrat. ʒij; Syr. zingiberis, Aq. menth. pep- æ, āā ℥j. Misce. Shake bottle and give one teaspoonful whenever e is nausea.

Whenever there are tenesmus or streaks of blood in the stools, and in cases which are exceptionally obstinate, the following will be found ul as a clyster: ℞. Argent. nitratis, gr. j; Bismuth. subnitratis, ℥ss; il. acaciæ, Aquæ, āā ℥ij. Misce. The whole of it or a part may be n through a glass or gutta-percha syringe, and retained for half an or one hour by a compress. Towards the close of the hot weather in the fall months, we are often asked to examine and treat protracted s, that have been gradually losing flesh and strength since the diar- a began several weeks previously. The febrile movement is usually erate, the appetite poor, the stools are not healthy looking, and prob- y less frequent than at first, though still too frequent. For such cases following should be prescribed, which is both tonic and astringent: ferri nitratis, gtt. xxvij; Tinc. colombæ, ʒiij; Syr. simplic. ℥iij. e. Give a teaspoonful every two or three hours to an infant of one . The beef wine and iron of the shops, of late extensively employed New York as a general tonic, also has a good effect, for the iron which ntains is mildly constipating. The dose of it is also one teaspoonful an infant of one year.

Quinia has not seemed to me to act well in diarrhœal affections of in- y, apparently increasing the number of stools. It should never be d in acute cases. If ever admissible, it is in the chronic and wasted s as a tonic, and not for its anti-pyretic effect.

The tincture of digitalis as a heart tonic, in cases of impending or es- lished spurious hydrocephalus or hypostatic pneumonia, is a good ad- ant. It should be given in one-drop doses every third hour, while e active stimulation by the carbonate or aromatic spirits of ammonia employed. Digitalis will also probably be found useful in any case at- ded by weak and rapid pulse, even when there are no symptoms of the plications alluded to.

I have said nothing in reference to the use of pepsin and lactopeptine, I have never been able to satisfy myself to what extent, or whether y materially assisted the digestive function in this disease. Experi- ents show that the quantity of food which either one in ordinary me- icinal quantity digests is very small.

Hospital Notes.

Ascites Successfully Treated by Tapping with Southey's Fine Trocar.

Henry S——, aged about thirty years, was admitted into the West London Hos pital, under the care of Dr. THOROWGOOD, on November 17, 1879. The patie had been in the army, and while in the West Indies was laid up with an attac of "break-bone fever." He stated that he had never drunk much, his usu beverage in the West Indies being rum, and this on returning to England h exchanged for gin. He got on pretty well till 1876, when he was invalided fro the army at Aldershot on account of bronchitis and heart disease. Gradually h noticed some swelling of his right foot, and then he found his abdomen larg than usual. During September, 1879, he was under the care of Dr. Fish as o patient at the West London Hospital with well-marked ascites, and on the 17 of November he was sent into the hospital.

On admission his abdomen was distended and very tender, the circumferent measurement at umbilicus was thirty-seven inches, a few enlarged veins were s on the surface, and the left lobe of the liver was tender and swollen. He ha mitral regurgitant murmur, and subcrepitant râles were audible at the lung bas He had never vomited blood, or passed any by the bowels; had complained cough, burning acid risings, and a good deal of soreness and pain at the epig trium.

On Nov. 21, pulse 84, urine four pints, clear, free from albumen. Ord five grains of compound ipecacuanha powder and three grains of mercury- chalk powder every night.

The remedies not making any reduction in his ascites, on Dec. 2, Mr. Bla placed him on his right side and introduced one of Dr. Southey's fine trocar the mesial line, two inches below the umbilicus. The instrument was reta for five hours, during which time eight quarts of clear, greenish-looking f drained away. In the evening the temperature was 100°, and the man co plained of much pain over the abdomen. Pulse rapid and irregular. To c tinue the powders as before.

The patient gradually improved, and on Jan. 8, 1880, was allowed to le the hospital, feeling himself quite well. The abdominal tenderness had subside the belly was flat and resonant at the lowest part of each flank, and now measu 29.5 inches at umbilicus. The tongue was clean; appetite good, and liver duln normal. For a week he had taken nitro-hydrochloric acid, with taraxacum infusion of gentian.

The point of interest in this case seemed to be the value of gradual evacuati of the ascitic fluid. The marked abdominal tenderness rendered it advisable give small doses of Dover's powder before the operation to keep the intestin quiet. The valvular disease of the heart was another reason for taking away t fluid very slowly.

The increased temperature after the operation, the pain and tenderness co plained of by the patient for several days, and the quick and irregular pulse, showed that the precautions were not likely to have been taken needlessly. Th fine trocar and tube had previously proved beneficial in the case of a man in t hospital with enormously swelled legs, on whom Mr. Blamey operated, and t case of ascites seemed quite a fitting one to treat on the same principle. D Southey had very kindly explained every detail in the management of the troc and tube, and the result was as satisfactory as could be desired.—*Lancet*, Mar 6, 1880.

MONTHLY ABSTRACT.

Anatomy and Physiology.

omalies of the Twelfth Rib, and their Bearing on Nephrotomy.

Holl reports in Langenbeck's *Archiv für Chirurgie*, Band xxv., Heft esting case in which nephrotomy was attended with disastrous results, uence of an abnormal condition of the twelfth rib, which had been l in the early stage of the operation. The patient, who was under the ofessor von Dumreicher, was a man, aged 33, who had suffered for s from calculous disease of the left kidney, resulting in pyonephrosis, tic suppuration, and, finally, cystic disorganization of the organ. In ce of the severity of the symptoms at the ultimate stage of the disease, right kidney was believed to be healthy, it was decided to have re- ephrotomy. The operation was undertaken on August 6, 1877, and ertical incision made in the left lumbar region, commencing about two ow what was supposed to be the twelfth rib. The diseased kidney to be inclosed in a thick covering of rough cicatricial tissue, and almost of the organ had been converted into a thick-walled sac containing a luid. In consequence of some difficulty in enucleating the superior the kidney, the incision was extended upwards. Whilst the dense tissue was being divided near the lower margin of the rib, a whizzing heard, and the patient immediately became cyanosed. It was evident ft pleural cavity had been opened, and that pneumothorax had resulted. ation of the deep portions of the lumbar incision, it was found that felt before the commencement of the operation, and used as a guide, eventh and not the twelfth, which could now be felt very small and in tary state. A further attempt was made to remove the kidney, but, ence of collapse of the patient through dyspnœa and much hemorrhage, ion was not completed. The patient died on the following day. At sy, an opening through which the little finger could be passed was he lower part of the pleural cavity. The left lung was collapsed, and d by a considerable quantity of sero-purulent exudation. The twelfth nall and short (3½ centimetres in length), and its outer extremity did l to the inner margin of the lumbar incision. The upper end of this ad exposed the lower margin of the eleventh rib. Professor Simon, odern surgeons to advocate and to perform nephrotomy, pointed out welfth rib was one of the most important guides in this operation, but ention the fact that this bone not unfrequently exists in a rudimentary or is altogether absent. As the twelfth rib is intimately connected with a, and is the only safeguard against injury to this membrane in the course ration, it is evident that an abnormal condition of this bone may seriously nephrotomy, and not only render the operation very difficult, but also death of the patient. Dr. Holl, struck with the importance of the ed by the twelfth rib in the operation of removing the kidney, has eries of investigations on sixty human skeletons, with the object of de- g the frequency and variety of abnormalities of this bone, and also the of the diaphragm and pleura in cases where abnormality of the rib exists. The twelfth rib he found almost always shorter than the eleventh, th average lengths being three inches and a quarter and four inches and a thir In forty-four instances, the twelfth had not more than half the length of th eleventh rib. In twenty bodies out of thirty-six the twelfth rib could not be f on superficial examination and before dissection, the eleventh rib being apparen the last. In the total number of sixty skeletons, the twelfth rib was altogeth absent six times. In abnormal conditions of the twelfth rib, the eleventh r usually remains normal, save that its free extremity is somewhat depressed, that the space between the tenth and eleventh ribs is widened. Shortening the twelfth rib may occur on both sides or on one side only: when unilateral, occurs more frequently on the right side; it occurs more frequently in males th in females. No constant coexistence was found of any abnormality of the ve bræ, as to arrangement or number, with absence or abnormal size of the twel rib. If this rib be wanting, the corresponding vertebra has no costal articu facet, and presents a connecting link between the dorsal and lumbar verteb In cases of abnormality of the last rib, the posterior attachments of the diaphra usually occupy their normal position. The pleura, therefore, being no lo protected by the twelfth rib, and passing down below the eleventh rib, is v liable to be wounded during nephrotomy, unless the abnormal condition h been previously recognized and care taken to avoid such an accident. T surgeon, before commencing the operation, should count the ribs, and, if he the twelfth very short or absent, ought not to carry his knife over a line dr horizontally outwards from the lower margin of the spinous process of the tw dorsal vertebra. The twelfth rib, Dr. Holl states, when short, has no valu a guide in nephrotomy, and ought not to be regarded as such, save when its extremity extends for some distance beyond the outer margin of the sacro-lum muscle. Dr. Holl agrees in the opinion that was held by Professor Simon the danger of excising the twelfth rib in nephrotomy, and disapproves of proceeding on account of the great risk involved of opening the pleural ca —*London Med. Record*, April 15, 1880.

Materia Medica and Therapeutics.

On Antiseptic Dressings.

The following extract, from Professor **Bardeleben's** *Text-Book of Surg* is published in the February number of the *Medicinisch-Chirurgische Ru chau*. The most convenient and efficacious of antiseptic dressings are those c taining carbolic acid. Thymol is a less convenient agent, merely on account the difficulty in obtaining a sufficiently strong solution. Both agents are v volatile. Dressings, therefore, in which either is mixed with lard or resin, so become useless. Such dressings should either be used when quite fresh, or closely packed in some air-tight receptacle. Moist dressings of thymol and ca bolic acid have the advantage that they may be readily provided and witho technical assistance, but they must be renewed from time to time. If jute used at the same time, the moistening of the dressings with carbolic acid thymol need not be repeated more frequently than once in twelve hours. Sa cylic acid is less soluble and also less potent as an antiseptic than the abov mentioned agents; but, on the other hand, it is not at all volatile, and dressin impregnated with it preserve their efficacy for a long time. The small crystal

ay be readily detached from dry dressings, and thus the antiseptic
the application is impaired and a dust diffused around the patient,
ry irritating to the mucous membrane of the air-passages and provo-
oughing and sneezing. This acid has this important advantage over
d and thymol, that it is much less irritating in its action on the skin
n surfaces. Not the hand of the surgeon only, but also the skin of
must suffer from the local action of carbolic acid. The most irritat-
sings is Lister's gauze, on account not merely of its carbolic acid, but
paraffin that it contains in large amount. Not only pain and redness
pustular eruption and superficial gangrene of the skin, may occur
use of Lister's dressings, especially if the bandaging be too firmly
arbolic acid, as C. Hueter remarks, acts not only as an irritating but
ralyzing agent, particularly on the small vessels. Hence the active
m all fresh wounds to which a solution of carbolic acid is applied in
spray. In solutions of more than three per cent., carbolic acid acts
Whether the burning pains caused by the prolonged application
of carbolic acid, even in weak solutions, be due to the direct action
on the nerves or to dilatation of the small vessels and consequent stasis
nnot be made out. Thymol has no advantage over carbolic acid in
for, even in solutions of one per thousand, it excites severe burning
applied to the skin. It does not, however, cause any paralysis of
ssels. With the use of carbolic acid, the burning pains give way to
with the use of thymol, this change does not occur. Boracic acid
hich may be used whenever carbolic acid or thymol cannot be con-
safely applied, have this advantage, that they may be kept for a
thout being deprived of their efficacy, boracic acid being non-volatile.
zinc dressings should not be applied directly to a wounded surface,
cts as a caustic. For the same reason, any wound-secretion absorbed
of zinc dressing should not be allowed to come into contact again
face of the wound, or to accumulate in its vicinity. If these precau-
en, chloride of zinc will be found, in combination with jute, a very
ptic dressing. Of much greater importance than the local irritation
e produced through the application of antiseptic dressings, is the
the danger that may arise through the absorption of any of such
e only agent that need be considered in this respect is carbolic acid, for
the above-mentioned antiseptics can be absorbed by the organism from
s in such quantities as to excite serious disturbances. Carbolic acid is
poison. That it is very frequently absorbed both from moist and
essings, may be proved by the frequent occurrence of a characteristic
ecognized change in the urine. The colour of this exuded fluid is at
een, subsequently, after some exposure to the air, dark brown, and
; the sulphates disappear and are converted into sulpho-carbolates.
nstanding this alarming symptom, the general health of the patient,
rwise affected, usually remains good. In some instances, however,
fails, the patient feels dull and is apathetic, and there is nausea and
vomiting. The intensity of these disturbances stands in no close
the intensity of the urinary staining; with the urine very dark in
patient may still feel quite well. It is not imperatively necessary to
the use of carbolic acid dressings when the urine becomes stained;
as the above-mentioned general symptoms are manifested, some other
ressing should be substituted.—*London Med. Record*, April 15, 1880

spurious hydrocephalus. Refraining from its use for such patients, and giving it in the doses and with the interval stated above, I have almost never had occasion to regret its employment, though prescribing it several times each day during the hot weather, in private and asylum practice. Drops are of very variable size when falling from the mouth of a bottle, and the dropper should always be employed, so that the drop may be as nearly as possible half a minim. The metric system insures more exactness, but we are not yet ready for it in this country. In certain severe cases the opiate may be given for a time every two hours.

The bismuth subnitrate is applicable to all cases, possessing no disadvantages, and producing no ill effects to limit its use. It may be given safely and with advantage in all stages of the malady as long as there is vomiting or diarrhœa. It is an efficient anti-emetic and antiseptic. It seems to act mainly locally, restraining the stools, increasing their consistence, and producing a soothing and curative effect upon the inflamed surface. It probably retards fermentative changes. It becomes a bismuth sulphide as dark as charcoal in the stomach, as I have observed at autopsies, and if taken in large doses, as it should be, it renders the stools dark. It sometimes taints the breath like that from onions or garlic, but I am informed that this is probably due to some impurity. It has long been in use in practice, but in insufficient and inadequate doses, for infants, until within recent years. An infant of one year should take it in doses of ten or twelve grains, and one of six months in six or eight grains.

Although we do not wish to produce alkalinity within the stomach, as the pepsin in its normal state is acid, and necessarily so for healthy digestion, yet in the "summer complaint" there is an undue development of acids, probably mainly the lactic. Therefore alkalies, as lime-water and the preparations of chalk, have been long used in this disease, and with apparent benefit, especially in the more acute cases. Alcohol, in moderate quantity, aids digestion, and is a heart stimulant. It is quickly eliminated from the system of the infant, and should be given at intervals of one to two hours to those who require it. It is given best in the form of Bourbon whiskey, brandy, or sherry, port, or Madeira wine. It is urgently demanded when, from failing heart action, hypostatic congestion of the lungs or brain is occurring or impending. In spurious hydrocephalus, which complicates many severe and protracted cases, its timely use aids materially in averting the danger. Many years ago Dr. Gooch, of London, was in the habit of employing in such cases of failing heart action the aromatic spirits of ammonia, and in five-drop doses sufficiently diluted in water it is a good stimulant and antacid.

Mild cases do not require special treatment designed to reduce temperature, as it is but moderately elevated. If the heat of head be moderately increased, a cloth wrung out of cold water should be constantly applied to it, and especially should the nurse be forbidden to cover the head except in the lightest and coolest manner, either in the house or out-door. In those severe cases known as choleriform diarrhœa, or cholera infantum, more energetic anti-pyretic local treatment is required. This form of intestinal catarrh, which usually occurs quite abruptly, having been preceded either by a state of health, or a mild diarrhœa, and is characterized by frequent watery stools and rapid loss of flesh and strength, is attended by a temperature unusually high, namely from 104° to 106°, or even higher. Such great elevation of temperature involves danger, and the prompt use of measures designed to reduce it constitutes an important part of the treatment. A bladder containing ice may be applied to the ion. (2) The erythema appears on the face, neck, abdomen, over , upon the extreme surfaces, and upon the back of the hands and It occurs after eating, and after drinking alcoholic beverages. There y no fever, and the duration of the eruption is very short. (3) The often accompanied by dyspnœa and intense palpitation. (4) The are only observed in persons who are predisposed to it. (5) It be due to a paralysis of the vaso-motor centres in the same way as in anying dyspnœa and palpitations. Eruptions due to chloral have ved by Schüle in Germany, and by Creighton Brown and Winter is country. French writers scarcely allude to them, with the excepyor, who has brought forward an interesting communication upon the n nearly all the cases published by M. Mayor and M. Martinet it was he eruption reappeared on renewing the dose of chloral. The amount equired to produce the eruption does not appear to be of any great from the point of view here adopted. The explanation of its causes M. Martinet, although probable, yet remains to be proved.—*Prac-* rch, 1880.

Medicine.

The Neurotic Theory of Gout.

mber of *Brain* for April, 1880, Dr. DYCE DUCKWORTH, Assistant St. Bartholomew's Hospital, enters a plea for the neurotic theory of is based upon the following points :—

end that the diseased conditions which are recognized as of unequi- nature, are primarily dependent upon a functional disorder of a defi- the nervous system, and that, thus, gout is a primary neurosis.

here is much in the nature of the malady itself, and much evidence by way of analogy, to warrant the conjecture that the portion of the em specially involved is situate in the part of the medulla oblongata, bly, may be placed a trophic centre for the joints.

he gouty neurosis may, like others, be acquired, intensified, and trans- that it may be modified variously, and commingled with other neu- it may suffer metamorphic transformations, or be altogether re-

his diathetic neurosis imposes its type upon the affected individual in ritional modes, affecting the assimilating and excreting powers, ex- rked peculiarities in nervous impressibility, and determining, in more ee, a physiognomy of the gouty.

a large part of the phenomena known as gouty, are due to perverted uric acid and sodium salts in the economy, resulting from the morbid mentioned under the last head. Thus, there is excess of urate of blood before, and during, gouty explosive manifestation, and there is on (by nervous influence, in all probability) either of this salt to the t (Garrod),[1] or there is a too free formation of it at these inflamma- , whence it is deposited locally, and also set free into the circulation

l excretory power for uric acid appears to be temporarily inhibited as

---

Lecture on Pathology and Therapeutics." (London, 1867: p. 137.) H. s, M.D., F.R.S.

part of the process of gouty paroxysm. This measure of renal inadequacy wo appear to prevail in varying degree as a part of the specific neurosal disorder. chronic gout, when structural disease has occurred, either tubal, with depositi of urate of soda, or interstitial, with shrinking of the organs, the renal in quacy may admit of more mechanical explanation.

6. That in primary, or inherited, gout, the toxæmia is dependent on gouty neurosis; is the outcome, in whatever degree, of it, and is therefor secondary manifestation.

7. That, in what I term Secondary, or acquired, gout, the toxæmia is dire induced by such habits as overload the digestive and excretory organs, and c stantly prevent complete secondary disposal of nutritional elements of food; if, together with such toxæmia, distinctly depressing and exhausting agen affecting the nervous system, come into operation, the special neurotic manife tions of the gouty diathesis will occur, and be impressed more or less deeply u the individual and his offspring.

8. That this theory of gout, better than any other, correlates all the kn factors concerned in the production of the varied symptoms of the malady; while it displaces its humoral pathology from the pre-eminence it has so occupied, it takes full cognizance of it, and seeks to place it in a clearer rela to the phenomona of the disease.

9. That if it be desirable to refer various maladies to their distinct plac pathology, without reference merely to their chemistry, histology, or neuro the affection known as gout may perhaps most correctly be relegated, along some others, to a class of diseases which may be termed neuro-humoral.

10. An argument is adduced from the *juvantia* afforded by colchicu favour of the theory which has been set forth.

Persistent Priapism, not connected with Lesion of the Central Nervous S

Dr. George L. Peabody, Medical Registrar and Pathologist to the York Hospital, reports (*New York Med. Journal*, May, 1880) an inter case of long-continued priapism not dependent upon injury to the spinal and reviews the other cases of similar character which have been from tim time recorded in medical literature. He finds the following to be the mos portant facts with regard to this form of priapism:—

1. It is to be regarded as an occasional symptom of leucocythæmia.

2. It may come on without any assignable cause in a patient apparent perfect health, though it usually attacks anæmic persons. It sometimes fo sexual intercourse, though this is to be regarded as exceptional.

3. It may last from a few days to two months, and has lasted a longer though rarely.

4. It is extremely painful, causing insomnia, nervous exhaustion, and ge physical prostration.

5. It has occasionally yielded to profuse blood-letting. This procedure to be recommended, except in robust subjects. Free incisions into the co cavernosa have occasionally caused its subsidence, but they are to be regard unsafe on account of the prolonged suppuration which has followed them. ical treatment has proved entirely useless as far as the cure of the conditi concerned. Local applications containing camphor and other soothing ingredi have diminished the pain.

6. The prognosis is not good, both on account of the cachexia with which commonly accompanied, and on account of the fact that it is frequently follo by impotence.

7. The corpus spongiosum is usually not affected.

A valuable bibliography is appended.

Diabetes and Sepsis.

paper (*Deutsche Medicin. Wochenschrift*, Jan. 3 and 10, 1880), **Roser**
al attention to the occurrence of gangrenous or ulcerative processes in
uffering from diabetes. As a rule, in cases of gangrene occurring with-
efinite cause, the tendency is to attribute it to some septic agency.
wever, points out that, in these cases, diabetes is often present, and,
is the case, he states that a cure may be obtained by attention to diet,
out any special antiseptic measures. In support of this view, he cites
n his own practice of progressive gangrenous inflammation of the foot
antidiabetic diet; other cases occurring in his own practice, in that of
rchal, and others. Reference is also made to cases of sudden death,
en occur in diabetic cases, and which may happen after even slight
. He confirms Marchal's statement that, "in cases of obstinate
eruption of carbuncle, diffuse phlegmonous inflammation, gangrene,
rine should always be examined for sugar."—*London Med. Record*,
1880.

—

An Undescribed Eye-Symptom in Glycosuria.

calls attention (*El Siglo Medico*, Jan. 1880, No. 1361) to a case of
which he observed a symptom hitherto undescribed, namely, a dimi-
the refractive power of the eye. The patient was a woman, aged 61,
antecedents, in whom symptoms of glycosuria became developed after
Simultaneously, sight became impaired, and glasses that had hitherto
reading were now found to be too weak. There was a manifest hy-
ia of 1.25 D, and vision was reduced to one-half. At this period, the
sugar passed daily amounted to 229.04 grammes. At successive visits
t of sugar was found to be steadily decreasing, and, *pari passu*, the hy-
ia also. Finally, five months after the first examination, it was found
eyes were once more emmetropic, while every particle of sugar had
d from the urine. The author explains the symptoms by an alteration
ex of refraction of the vitreous humour, due to a change in its chemical
n. The vitreous body offers a concave surface to incident rays, and,
tly, its refraction is the exact reverse of that of the cornea and crystal-
efore, any increase in its refractive power will result in a diminution
ractive force of the eye as a whole.—*London Med. Record*, April 15,

—

e Appearances, probably of Parasites, in the Voluntary Muscles of Enteric Fever.

e meeting of the Pathological Society of London (*British Med. Journal*,
1880), Dr. Buchanan read, on behalf of Mr. W. H. **Power**, a paper
bject. Mr. Power's attention was first called to it by the discovery of
worms closely resembling trichinæ in the body of a boy who had died
the training-ship *Cornwall*, of a disease supposed to be typhoid fever,
affected many of the boys in the ship. Investigation rendered it nearly
at in all the cases the disease had been parasitic in its nature, rather
eric. The parasites resembled trichinæ in size, but they were not
and they were more transparent than trichinæ generally were. This
due to the rapid course of the disease in this case, and to the fact that
ination was not made until two months after death. In order to follow
atter, Mr. Power made examinations of the voluntary muscles in two
undoubted typhoid fever. The first case was a young man, a patient in

St. Thomas's Hospital under the care of Dr. Cory, admitted for typhoid fev who had died of perforation on the twenty-third day of the disease, the bo being found *post mortem* to present well-marked typhoid ulceration. In pectoral muscle were bodies resembling parasitic worms. They were v numerous, and when first seen were apparently living. In length and in brea they were about one-fourth the size of the trichina spiralis, and there was interior canal which appeared to be covered at one part by some internal ti or organ. Similar bodies were found in the muscles of a boy who died in Gre wich Hospital from peritonitis, at an early stage of unquestionable typhoid fe In neither case were all the muscles affected, the diaphragm being in both from the worm-like bodies. Further examination led to the discovery of sma bodies, possibly having some relation to the larger bodies, but much numerous than the latter. They were, however, not easily seen, a very sli interference with the slide being sufficient to remove them from view. larger parasite-like bodies were more numerous in portions of the muscle wh had undergone decomposition; but this was not true of the smaller bodies. was doubtful whether the increase in the number of the larger bodies was ap rent only, or whether it depended upon actual growth or multiplication. author of the papers did not profess to do more than record the observed fa with a view to encouraging investigations on the part of other pathologists.

Syphilis as a Cause of Tabes Dorsalis.

Erb has previously drawn attention to the frequency with which a histor syphilis may be obtained in cases of tabes (*Deutsches Archiv für Klin.* Band xxiv). He now reports (*Irrenfreund*, Jan. 1880), from a series of observations, that out of 33 typical cases, he only found 4 without pre syphilitic infection. Of the other 29, 24 had had secondary symptoms, an remaining 5 a primary sore only. In order to show that this history is speci tabes, the author carefully examined 85 male patients over 25 years of age, fering from various other nervous disorders, for previous syphilis or chancre. these, 71 had never had the disorder, leaving only 14 who had. The propor are these: of the 33 cases of tabes, 88 per cent., and, of the 85 cases of nervous diseases, 14 per cent. only had had syphilis. The time at which tabes supervened is thus given: within 4 years of infection, 5 cases; from 10 years, 18; from 11 to 12 years, 3; many years later, 3. In most of cases it was observed that the syphilitic symptoms had not been of a se nature. The author states that symptoms of syphilitic disease of the should be carefully sought for in all cases of tabes. He regards the que whether syphilis is merely a predisposing, or a direct cause, as still open, inclines to the latter view, and considers that two classes of cases should be re nized, the specific and the non-specific. In a number of the syphilitic ca active antisyphilitic treatment had been followed by improvement or arre the disease; prognosis must, however, be most guarded, for syphilitic scler are always highly intractable, and there is probably an actual lesion of ne tissue which is known to have little or no power of repair. In a discussion wh followed the reading of the author's paper, Dr. Mayer stated that, among cases of tabes, he had only found three without any history of syphilis.—*Lon Med. Record*, April 15, 1880.

Epilepsy in Syphilitic Patients.

Dr. C. **Pellizzari** describes three cases in *Lo Sperimentale* for 1879 (abst in *Wiener Med. Wochenschrift*, No. 13, 1880). In the first case, the subj

n aged 38, who sixteen years previously had had cutaneous syphilis, of
scars were still present. The left half of the face and the left upper
been the seat of convulsive movements for about a year, and defecation
rition occurred involuntarily. Soon after his admission, the left leg
bserved to be affected, and later the whole body. Death was preceded
derable rise of temperature. At the necropsy, the cerebral lobes and
nater were found to be adherent, and there was a considerable devel-
connective tissue in the cortical substance of the brain. In the second
patient was eight years old, the child of a syphilitic mother. It was
ve suffered only a short time from unilateral convulsions. No direct
d be discovered beyond thickening of the pia mater of the right para-
be. The third patient, a man aged 36, had been syphilitic sixteen
epileptic two years. At first he had only headache, afterwards stut-
convulsions, and then aphasia. At the same time with the headache,
eared on the lower lip. This healed under mercury; the treatment,
had no effect on the convulsions, which affected the right side; and his
ecame impaired while he was taking mercury. Consciousness was still
d a short time before death, even when the convulsions affected both
eath was preceded by a rise of temperature. There was softening of
be of the brain as far as the corpus striatum; the meninges in this part
thickened and adherent.—*British Med. Journal*, April 24, 1880.

The Treatment of Epilepsy.

R. Gowers concluded his recent course of Gulstonian Lectures before
College of Physicians with the following interesting remarks on the
of epilepsy.

tment of epilepsy is a subject on which numerical analysis gives little
large number of cases are under observation too short a time to enable
of remedies to be fairly estimated; and of the cases in which benefit is
e have no means of ascertaining how many relapse when treatment is
ed. My notes of the result of treatment in this series of cases extend
s only. In the remainder, either the period of observation was too
ust conclusions to be drawn, or, in the press of out-patient work, the
of remedies was not noted with sufficient precision. The effect of treat-
ore likely to be recorded when it is distinct and considerable than when
. Hence the following figures have no relative value. Of the 562
attacks ceased while the treatment was maintained in 241; doubtless
hese relapsed when treatment was discontinued, but in a few I have
to ascertain that the patients remained free from fits even for years
ceased to take medicine. In 266 cases improvement short of arrest
ed; the fits being reduced in many to $\frac{1}{20}$, $\frac{1}{30}$, $\frac{1}{50}$, and even $\frac{1}{200}$ of their
quency. In 55 cases little improvement was obtained by any method
ent.

orbids me to enter at any length on the details of treatment, and I can
nore than mention the remedies which in this series of cases were of
inct service. The subject of possible modes of action it is better to
ost untouched. It may be doubted whether a rational therapeutics of
s yet possible. At any rate, up to the present time remedies used
ly have been of most service.

gh the results show that we must not only rely exclusively upon bro-
our treatment of epilepsy, they show also, as might be expected, that
our chief trust must still be placed. Of the arrests of fits, 66 per cent.,

and of the improvements short of arrest, 62 per cent., were due to bromid given alone. Of the three alkaline salts of bromine, that of potassium deserv I think, as it has popularly received, the first place. I have made a careful com parison between the salt of sodium and potassium in a series of about fifty cas substituting the one for the other. In a few cases the sodic salt appeared to better; in the great majority it was distinctly less useful. Bromide of amm nium possesses slightly more power than bromide of potassium, but this is n greater than the larger quantity of bromine which it contains will account for.

The period after its administration at which the maximum effect of a dose of br mide is obtained varies, I believe, with the dose. The larger the dose the long is the maximum effect deferred; the smaller the dose the sooner does it occur, a the sooner is its action over. When small doses are employed in cases in wh attacks occur at regular times, they should not therefore be given more than t or three hours before the attack is expected. This is contrary to some opini which have been expressed, but I have several times known attacks arrested wh a dose was given some two or three hours before the fit was expected, which we not arrested when the same dose was given twelve hours earlier.

The effect of bromide upon fits appears to be for a time cumulative, just as indeed, its action in causing bromism. Attacks may continue under its admi tration for a time, and yet ultimately cease without any increase in the dose. the other hand, still later, tolerance, or rather indifference, may be establish and attacks which have been for a time arrested may ultimately recur.

Drugs which increase reflex action, such as strychnia, are now believed to so by lessening the resistance in the nerve-centres involved. Bromide di ishes reflex action, antagonizes strychnia, and it is probable that it does so increasing the resistance in the centres. If the view above expressed be corr that the morbid state in epilepsy is essentially an instability of the resistanc the cells, it is also probable that bromide acts by increasing the stability of resistance.

Bromide is commonly administered in a continuous course, in such mode doses as will just suffice to keep the fits in check. Given thus it needs to be gi frequently. I have more than once observed that a daily quantity which gi in two doses did not quite arrest the fits, arrested them completely when giv in three doses. If, therefore, the greater convenience of infrequent doses, or two daily, is preferred, a somewhat larger quantity needs to be given.

When bromide is thus given continuously, it has not seemed to me desirabl increase the daily dose beyond a drachm or a drachm and a half. If this d not arrest the fits, I have very rarely found that larger doses succeed so well the combination of bromide with other drugs. But it is, I think, open to qu tion whether this method of administration, using doses only just sufficient arrest the fits, is the wisest in all cases. If bromide cures epilepsy, as with doubt it does sometimes, it must be by effecting a nutritive change in the nerv cells corresponding to its action, whereby they are rendered permanently mo stable. That it, or any other drug, does good in epilepsy by influencing the va cular state of the brain, appears to me without even probable proof. Even such were its action, we are only driven back to a similar influence in increasi the stability of the cells of the vaso-motor centre. There are, I think, man grounds for the belief that the change in the nutrition of the cells may be pr duced more effectually by subjecting the patient *for a time* to the full influen of bromide, giving doses much larger than are needed to arrest the fits, in t hope of producing more readily a permanent nutritive change. In giving br mide thus I have preferred large doses at intervals of two or three days, grad ally increasing the dose until it is as large as can be well borne, and then dimi

The largest single doses which I have given in this way have been ne ounce. This in some patients produces slight stupor, sometimes s maximum on the second day after the dose. In other cases it pro- little disturbance beyond headache. From the marked differences ients present in their tolerance, it is not well to begin this method of with a larger dose than four drachms.

ie of the various combinations of bromide with other drugs was tested, ossible, on a uniform plan. First, bromide was given alone for several d then an additional drug was added to the same dose of bromide, and ratched for several months longer. Of the various combinations which mon use, those with digitalis and belladonna unquestionably deserve, ve commonly received, the first place. Digitalis is one of the oldest or epilepsy. It was recommended by Parkinson two hundred years as been perhaps for a still longer time a popular remedy for this dis- tain rural districts in the west of England. I have met with no case given alone, digitalis arrested the fits for more than a few months, but cases it effected very distinct improvement. The combination of digi- omide, however, was distinctly more useful than bromide only, in no xty-three cases. In more than half of these, thirty-seven cases, the sed under its use, although they had continued under bromide alone. es in which cardiac disturbance was associated, the combination was ys superior to bromide alone; but its use is not confined to these cases. of nocturnal and other forms of epilepsy yielded to the combination, ie attacks had continued under bromide, and this when there was no cardiac disease. I know of one patient with nocturnal epilepsy who, rs, under this combination, has not had a single fit, although the at- red every few weeks on bromide only.

cases belladonna alone will arrest attacks. I have met with only one ch attacks, which continued on bromide, ceased entirely when bella- substituted, and this was a case with hystero-epileptic symptoms. nation of bromide and belladonna, however, was distinctly better than one in 35 cases, and in 15 of these arrest of the fits was thus obtained.

emp was first employed in epilepsy by Dr. Reynolds, and is sometimes lue. In one case the attacks were invariably arrested for many months recurring only when the patient ceased attendance, but twice on his ttendance the drug instantly arrested the attacks. When bromide was for the Indian hemp, the attacks at once recurred. Combined with is also sometimes useful, and seems to exercise most influence over cases in which there is persistent headache. The same fact has seemed combination with gelseminum, which is occasionally of marked ser-

of opium in epilepsy has long been advocated by Dr. Radcliffe, and ses it is certainly effective. The combination of bromide and morphia ely found to present special advantages. In the status epilepticus in cks occur with great frequency and severity, and where bromide, even ses, was useless, I have found small hypodermic injections of morphia rvice.

nbination of bromide with aconite and hydrocyanic acid I have also found in some cases slightly better than bromide only. The addition o bromide has been lately said to increase its effect. Occasionally this d in four cases of the series the combination was distinctly better than nly, but in many other cases it was ineffective. Even in the cases ts of inherited syphilis it has not appeared of special value.

Zinc unquestionably deserves some of the repute it has enjoyed for more th a hundred years as an anti-epileptic. Of the cases of this series in which it w employed it was distinctly useful in ten, but in only three did the attacks cea In three other cases attacks which continued under bromide ceased under bromi and zinc, and in a fourth they ceased under zinc, digitalis, and bromide. T oxide of zinc was the form commonly employed. Its nauseating influence co stitutes a serious drawback to its use, as toleration is difficult to establish, and have rarely succeeded in giving more than twenty grains a day. Bromide of zi has seemed of small value, and is borne badly. The addition of arsenic to b mide in no case produced any marked effect on the attacks. It was used in large number of cases on account of the readiness with which, it was found, t bromide rash could be prevented by its use.

Bromide of camphor, highly praised by Bourneville, was tried in a conside ble number of cases, but without any good results. Turpentine has been rec mended by Dr. Radcliffe, and I have seen it produce very striking benefit, only in cases of hystero-epilepsy.

The use of iron in epilepsy has been discountenanced by high authorities, grounds which are not altogether beyond question. In rare cases it incre the frequency of attacks; in the majority of cases in which it was used it borne without any ill result; in many the addition of iron to bromide was tended with a marked and permanent improvement, and in some cases iron al arrested the fits. The series includes 4 cases which ceased under iron only. 8 others in which iron alone was distinctly better than bromide, and 19 case which the addition of iron to bromide exercised a marked influence. In no than 11 cases attacks which persisted on bromide, ceased on the addition of i and remained absent as long as the treatment was continued.

In several inveterate cases of epilepsy in which bromide had no effect, I tried borax. In some cases it did no good, but in 12 its value was most disti I may mention one or two. In one, fits which had continued on bromide an zinc ceased entirely on borax for three months, and then only recurred when medicine was discontinued. In another case the fits continued, about one wee during three months' treatment on bromide and on belladonna. Borax was t substituted, the fits at once ceased, and for five months the patient had no single fit; then he had one in each of the two following months; the dose borax was increased, and up to the present time, eight months later, no ot attack has occurred. In a third case, one or two attacks occurred once a f night on bromide. Borax was substituted, and for five months the patient not a single fit. The doses given have been ten or fifteen grains twice or th times a day. It produces in some patients gastro-intestinal disturbance, rarely, a form of dysenteric diarrhœa. By others it is well borne, and one of patients has taken forty-five grains a day for twelve months without the sligh inconvenience, and says that no medicine has ever done him so much good. cases in which bromide fails, borax certainly deserves a trial.

The use of cocculus indicus in epilepsy, recommended by Dujardin-Beaume has lately attracted attention in consequence of the recommendation of Pla I have tried the alkaloid picrotoxine in a few instances, but in only one case it appeared to do good. My own experience of its use has, however, been sma and I am very much indebted to my colleague, Dr. Ramskill, for permitting to mention some interesting results which he has obtained by the hypoderm injection of picrotoxine. His experience of its effect on the fits when giv through the skin is nearly the same as my own of its employment by the mout In seven cases in which it was injected, in daily doses of from one to four mill grammes, no beneficial result was obtained; in most cases, indeed, the attack er more frequent and severe. Of course, we are not justified in assumhe effects of picrotoxine and of the cocculus indicus itself are identical. teresting fact has, however, been ascertained by Dr. Ramskill—viz., toxine in larger doses of from fifteen to eighteen milligrammes will ariably produce a fit in twenty or thirty minutes. In one patient, for according to the notes of Mr. Broster, who carried out the experiments), as daily increased, and when more than five milligrammes were insensation of giddiness followed, similar to that with which the attacks d. The same effect followed larger injections, and when the dose ighteen milligrammes a severe attack occurred thirty minutes later, ack always followed the injection of this dose. In another patient a gressive increase of the dose was followed by giddiness and headache, t milligrammes were injected. When the dose of fifteen milligrammes ed, a severe epileptic fit followed. Next day a second dose of fifteen nes did not cause a fit, but eighteen milligrammes, two days later, it in half an hour. After a week's intermission, twenty-four milliere injected, and a severe fit occurred in twenty-five minutes. In a nt a fit occurred after one injection of eight milligrammes, but ten milnext day caused no fit. Fifteen milligrammes, however, were followed thirty minutes, and a second injection of the same dose the following a fit in fifteen minutes. Seventeen milligrammes next day caused a minutes. In a fourth patient a single dose of eighteen milligrammes ten minutes, giddiness and slight dazzling before the eyes, and in tes there occurred the usual aura of an attack—a sensation of someing up the right arm to the top of the head, and numbness and twitchright thigh, but no fit followed, although the patient was stupid and ime just as after a fit.

other drugs which I have tried and found useless I may mention benla and nitro-glycerine.

ro-epilepsy bromides, sometimes useful, fail entirely much more fren in simple epilepsy, and the combinations with digitalis and bellaalso less frequently useful. Iron, especially guarded by aloes, is often hest value, quite apart from the existence of anæmia, and next to it of zinc, morphia, and turpentine.

horities have urged on different grounds that the diet of epileptics ain little or no animal food. In a few observations which I have made a patient under unaltered medicinal treatment for alternate periods on and without animal food, I could observe no difference in the attacks, t in one patient they were slightly more frequent in the periods when l was excluded, and in one patient hystero-epileptic attacks on ordibecame, when meat was excluded, severe epileptic fits, and again stero-epileptic when animal food was restored.

epilepsy the only treatment needed during the attacks is such care as the patient, as far as possible, from injury. It is very different with of hystero-epilepsy, which, from their character, severity, and long ften furnish the attendants with a task of no small difficulty, and which t always, be cut short by appropriate treatment. The patients often elves during the attacks, and some control is absolutely necessary. eady stated, restraint tends to increase the violence and makes the last longer. Hence considerable judgment is often required, so to rol as to be efficient and not too much. I have seen these patients put ded partitions and left alone, but I have never myself found this neces-

The slighter attacks can be arrested by closing the mouth and nose with a towel for some thirty seconds, after Dr. Hare's method. The profound effect on the respiratory centre, and the related higher centres, caused by the anoxæmia, seems to arrest the convulsive action. Cold water over the head is often successful if applied freely; in severe attacks a moderate quantity only excites redoubled violence, while a second gallon is often more effectual than the first. This has the disadvantage of drenching the patient's head, and often giving cold. When the mouth is open during the attacks a small quantity of water poured into it is often effectual. A much more convenient and more effectual remedy than water, however, is strong faradisation to the skin; applied almost anywhere it will commonly quickly stop the attack. It is rare that ovarian pressure will arrest an attack. In some cases all these means fail, even when thoroughly used, and I have known such attacks go on, in spite of skilled treatment, for several hours. Chloroform is of little use; its administration is a matter of extreme difficulty, often impossibility, and the attack is commonly renewed, when the influence of the anæsthetic passes off. The remarkable effect of nausea in relaxing spasm, led me some years ago to try the effect of injections of apomorphia, and I have found in it an unfailing means of arresting the attacks. After the injection of a twelfth of a grain in four minutes with certainty all spasm ceases, and normal consciousness is restored; in six minutes the patient will get up and go to the sink; in eight minutes will vomit, and afterwards, except for slight nausea, is well. A twentieth of a grain has the same action, but is rather longer in its operation. Moreover, I have found that the treatment is, so far as the hysteroid symptoms are concerned, curative as well as palliative, for the attacks in many cases ceased after a few paroxysms had been thus cut short.—*Lancet*, April 10, 1880.

False Diphtheritic Membranes.

Dr. Gaucher relates the following case (*Le Progrès Médical*, No. 34, 1879). The patient, a child, aged four years, was apparently moribund. The trachea was opened and a canula introduced, but the child did not breathe. The canula was withdrawn, a tracheal dilator used, and artificial respiration for some time performed, also without success. Dr. Gaucher then introduced the forceps, and drew out a false membrane, forming a complete cast of the trachea and bronchi. The patient immediately began to breathe and ultimately recovered.—*London Med. Record*, April 15, 1880.

A Case of Extreme Pharyngeal Stenosis the result of Syphilis; with Remarks.

Dr. T. Gilbart Smith and Mr. W. J. Walsham report (*Lancet*, April 17, 1880) the case of a woman, forty-seven years old, who was admitted on October 29, 1878, into the Royal Hospital for Diseases of the Chest, under the care of Dr. Gilbart Smith, suffering from prostration and dysphagia, accompanied by severe and recurrent attacks of dyspnœa. She gave a clear history of syphilis, which she had evidently contracted soon after her marriage twenty-six years before. She suffered for the first time ten years ago, from ulceration of the throat. This was relieved by treatment, but recurred at intervals up to the time of her admission. Eight months ago her voice became affected, and the movements of the tongue impeded. For six months she had been unable to swallow food, and for two months had suffered from severe and alarming attacks of dyspnœa. The tongue could not be protruded beyond the teeth; the right posterior pillar of the fauces was drawn backwards, and was adherent to the posterior wall of the pharynx. The uvula and a considerable portion of the soft palate had disappeared, leaving a clean semicircular border to the portion that

On laryngoscopic examination the epiglottis and vocal cords could

being placed in the aperture, the other in the ulcerated depression,
s made little by little from above downwards so that a full view was
f the cut surface of the tissues, and any vessel, if divided, could be
ecured. Care was taken to enlarge the aperture as much as possible
lirection as would allow the food in passing downwards to avoid the
nto the larynx. The parts were then forcibly dilated by the finger and
bougie. On Dec. 12th another incision was made at a different spot,
iglottis, vocal cords, and arytenoid cartilages came into view. When
left the hospital, Dec. 18th, the aperture measured three-quarters of
diameter, and admitted a full-sized œsophagus bougie.

t. 23, 1879, she was again seen by Dr. Gilbart Smith. The aperture
ntracted in the least. Stenosis of the pharynx appears to be very
e authors describe three distinct forms. The first, the most common,
between the naso- and mid-pharynx, and is caused by ulceration and
n of the posterior pillars of the fauces, and the drawing backwards and
adhesion of the soft palate to the pharyngeal wall.

this kind are reported by Messrs. Bradley, Cheevers, Reid, Coulson,
h. The second form is more rare; it occurs between the mouth and
nx, and is produced by the ulceration and contraction of the anterior
the drawing downwards and subsequent adhesion of the soft palate to
n of the tongue. A case is reported by Mr. West. The third variety
he lower part of the pharynx, as in the case now before the Society;
is being produced by bands of adhesions or soft or tough membranes,
tch across the pharynx, and glue the parts together. Other similar
reported by Schech, Gerhardt, Trendelenburg, Schroetter, West, and

hors draw the following conclusions: 1. That tracheotomy is called
s a temporary expedient to obviate sudden death from asphyxia, and
ntial factor for safe and satisfactory treatment. 2. That division, with
knife, presents advantages over other methods of treatment. 3. That
nall notches are preferable to a deep incision, and that, when possible,
should be divided from above downwards, so as to allow a full view of
e of the tissues divided. 4. That the aperture should be enlarged in a
so as to permit the passage of liquid food clear of the entrance to the

case the iodide of potassium was administered freely during the whole
the case. There was active ulceration going on by the side of the
l tissue; and there could be no doubt that the new tissue and thickening
to previous ulceration. The relief afforded to the dysphagia by the

operation obviated recourse to nutrient enemata, although perhaps they might have been resorted to with advantage. The effect of tracheotomy in arresting spasm of the glottis was an important fact. Allied to it was the occurrence in some cases of paralysis of the laryngeal muscles from the use of tracheotomy tubes; which has led to the suggestion that the tube should have an aperture made in it to allow of passage of air into the larynx from below, whilst the tube is worn.

Defect of the Pericardium.

Dr. **Hans Chiari** describes, in the *Wiener Medizinische Wochenschrift* for April 3d, a case of almost complete deficiency of the parietal pericardium. The subject was a man aged 46, who had died of cirrhosis of the liver and tubercular peritonitis, with old tuberculosis of the apices of the lungs. No special physical signs had been noticed during life on the part of the heart, except accentuation of the second sound in the pulmonary artery, which was attributed to the state of the lung. On removing the sternum, the heart was found lying quite free in the left pleural cavity, in immediate contact with the median surface of the left lung. Both lungs were adherent at the apices, and were here the seat of old indurations inclosing cheesy and calcareous masses; elsewhere they were œdematous. The apex of the right lung formed a separate lobe about the size of a hen's egg; and the upper lobe of the left lung was divided into two by a nearly horizontal fissure. The heart, which appeared normal in structure, lay in its normal situation with regard to the thoracic walls. The mediastinal layer of the left parietal pleura was found to the right of the heart, and extended into the right half of the thorax. From its left surface, along with the visceral pleura for the left lung, the visceral pericardium was developed, proceeding forwards from the hilus of the left lung. The transition from pleura to pericardium was for the most part direct, without folds. Only at the part where the pleura passed over the vena cava inferior there was a duplicature about three *centimetres* in depth, which, gradually becoming a crescentic fold, could be followed for seven *centimetres* along the posterior circumference of the auricle, as far as the hilus of the left lung. This duplicature contained some adipose tissue. The mediastinal layer of the right parietal pleura was in its usual situation. The mediastinum was only three *centimetres* wide; it contained a little fat, and the usual structures (aorta, œsophagus, etc.) in their normal position. The left phrenic nerve alone was abnormal in position: it lay on the outer surface of the pleura, where the mediastinal passed into the parietal portion, crossing the heart obliquely to the diaphragm, into which it passed at an almost right angle. The diaphragm itself appeared quite normal, except that the middle division of the central tendon was somewhat smaller than usual.—*British Med. Journal*, April 24, 1880.

The Diagnosis of Pericardial Adhesion.

After an analysis of the symptoms which have been given in earlier and in more recent times as diagnostic of pericardial adhesion, Dr. **Riegel**, in Volkmann's *Sammlung Klinischer Vorträge*, arrives at the conclusions (agreeing therein with the opinion expressed by N. Weiss in his work on the subject) that as yet we are far from possessing a constantly sure indication of the condition under consideration, and that it is only in rare cases that the diagnosis of pericardial adhesion can be readily made. This is especially the case when a high degree of systolic retraction of the apex of the heart, or even of a large portion of the neighbouring thoracic wall, is present. The presence of a systolic retraction points to little more than an impediment to the normal systolic movement of

; and other rare causes, which may lead to retraction, have to be ex-
If there be at the same time a diastolic collapse of the veins, or if the

terations in the Alimentary Tract in Pulmonary Consumption.

ri (*Bullettino delle Scienze Mediche*, January, 1880) states that, in
psies performed on patients who had died of pulmonary consumption,
lesions of the alimentary tract in 38; in the remaining 12, no such
re present. In 37 of the cases so affected the lesions consisted of
ted either on the tongue, pharynx, stomach, or large or small intestine,
the œsophagus, or rectum. In all cases, with one exception, the
re multiple, ulceration of the tongue, pharynx, or stomach existing
usly with ulceration of the intestines. In 12 cases the lesions were
o the small intestine; in 5 to the large, while in 20 they affected both
The author observes that, in cases where ulceration has been confined to
intestine, the large has frequently contained solid fecal matter, thereby
ting a fact already remarked on by Niemeyer, that ulceration of the
stines may exist without giving rise to diarrhœa. As a rule, the num-
xtent of the intestinal ulcerations bore a constant relation to the pul-
sions. In the small intestine, the ulcers were generally seated in the
tion of the ileum, although in some cases they were confined to the
valve, while in others they extended as high as the jejunum, and even
. These ulcers in the earliest stage appeared as small white spherical
the size of a pin's head springing from the mucous membrane. At a
e they became larger, and the mucous membrane had shrunk away
summits, thus leaving punctiform ulcers. In some cases, the ulcers
ted on Peyer's patches, and were multiple. In the large intestine, the
ere as a rule confined to the ascending colon, though, when numerous,
also found in the cæcum and around the vermiform appendix. The
marks on the extreme rarity of tubercular granulations in the large
as compared with the small. The article extends to a considerable
n analysis of each case being given, and ample references made to the
of the subject.—*London Med. Record*, April 15, 1880.

Eczema from Use of Atropia Collyria.

The remarkable susceptibility of certain individuals to particular drugs, evidenced by a constant relation between their use and the appearance of er tions of various kinds on the skin, has of late received much attention, especi in Germany, by Köbner and Behrend. Dr. JULIUS DONATH, of Baja (H gary), records (*Wiener Med. Wochenscrift*, No. 12, 1880) a case where introduction of a few drops of a 1 per cent. solution of sulphate of atropia i the eye was invariably followed by severe eczema and pseudo-erysipelat swelling and redness of the face and neck. The patient was a woman of fo five, of good constitution, with chronic disease of the left eye giving rise corneal opacity and synechiæ.—*Med. Times and Gazette*, April 17, 1880.

Treatment of the Itch at the St. Louis.

In a clinical lecture (*Gaz. des Hôp.*, Feb. 10) Prof. HARDY states that he since 1852 employed in the treatment of the itch the ointment composed of part of lard, a sixth part of flowers of sulphur, and a twelfth part of subcarbo of soda. So efficacious have proved thorough and almost violent frictions this, continued for twenty or thirty minutes, especially at the natural bends folds of the skin, that the cure is absolutely certain. Among from 4000 to adults so treated at the St. Louis, in only one instance was a repetition of frictions needed. The ointment, after the rubbing, should be left on for sev hours, or all night, without washing. Next day an emollient bath may be ta which may be repeated every twenty-four or forty-eight hours for a week.— *Times and Gazette*, April 10, 1880.

New Staining Fluid for Amyloid Organs.

Dr. CURSCHMANN, of Hamburg, has discovered that a substance called *me green*, which has been lately introduced into practical histology as a stai medium, has a peculiar affinity for amyloid substance, and colours it an int violet (*Virchow's Archiv*, vol. lxxix., part 3, page 556). The surrounding sues, that have not undergone degeneration, are stained green or bluish-gr and the contrast is therefore very striking, whilst the smallest spot of am disease can be readily discovered. Hardly less important than this discove the observation that methyl-green colours so-called hyaline-casts (*in situ*) u marine blue, so that these also can be readily distinguished in sections of the ney from the green-coloured tissues around, as well as from the violet am spots in which they may lie. Methyl-green, which can be purchased of chemist, is used for staining in the form of a 1 per cent. aqueous solution. few minutes' immersion of a microscopical section in this solution is suffici but sharper and more uniform coloration is produced by using a more d medium for a longer time. Preparations so made may be mounted in di glycerine, but not in Canada balsam, inasmuch as alcohol, turpentine, and o cloves quickly discharge the colour.—*Med. Times and Gazette*, April 17, 18

Surgery.

Accidental Inoculation of Syphilis by Tattooing.

M. ROBERT, a French army surgeon, gives (*Recueil de Méd., etc., Mi taires*, Nov., Dec. 1879) an account of eight soldiers who were tatooed by a m t the time from syphilis, and who had mucous patches about the mouth. tor used his saliva to dilute the ink employed, and also moistened the his mouth. Three of the eight soldiers developed syphilis, while five hough only one of them had previously suffered from that disease. he men, however, washed their wounds directly after the operation, ether with the fact that the tatooer did not use his saliva so freely in as in others, accounts, in M. Roberts opinion, for the escape of some . In the three instances where syphilis followed, the initial lesions n due course at the site of inoculation, which was in each case the rm, and were followed by enlarged glands and general syphilitic erup- d. *Med. Record*, April 15, 1880.

der is referred to an extremely interesting case of a similar character Drs. Maury and Dulles, in the number of the *American Journal of l Sciences* for January, 1878, p. 44.]

A New Treatment of Gonorrhœal Ophthalmia.

ADER, Ophthalmic Surgeon to Guy's Hospital, suggests (*Lancet*, 0) a new mode of treatment of gonorrhœal ophthalmia based upon t mercury, if thoroughly applied locally, has a destructive effect upon In vaseline, in itself of antiseptic origin, we have an invaluable means and keeping mercury in contact with mucous membranes, such as con- ethra, etc.; daturin or atropin are added to counteract disturbances ng the ophthalmia, may proceed from the iris and deeper parts of the Bader uses an ointment, consisting of nitric oxide of mercury one in one-fifth of a grain, vaseline one ounce.

s are reported in which the disease was of a severe type, and in which nt was used with most gratifying success. The ointment is applied camel's-hair brush beneath the upper eyelid, and the eye then bound smeared over with the ointment.

Corneal Maculæ.

Z OCANA, in a paper published in *El Genio Medico-Quirurgico*, No. des all consideration of corneal albugo or leucoma, which he considers ndelible. A macula, however, which consists in a number of corneal ich the normal course of development has been interfered with, is successful treatment. In cases where, together with maculæ, there chronic vascular condition of the palpebral conjunctiva, excellent be obtained by the use either of calomel or of red precipitate. In ple maculæ, apart from other complications, the author has obtained ctory results from a collyrium composed of tincture of opium and strength at first of 1 part in 8, gradually increased to 1 in 4. Should ome tolerant of the remedy, which will then lose much of its power, recommends a pomade composed of chrysophanic acid and vaseline, his is an active preparation, and requires to be used with discretion l quantities, once a day or more, according to the degree in which it .—*London Med. Record*, April 15, 1880.

Case of Hysterical Blindness with Spasmodic Squint.

, which MANZ records at considerable length (*Berliner Klinische rift*, Jan. 12, 19, 1880), presents a group of symptoms differing in cts from any of the recently described hysterical affections of the visual function. The patient was a delicate girl, by occupation a govern The following symptoms were developed whilst she was under observation; p in the head, inward deviation of the right eye, followed next day by inw deviation of the left, each cornea being turned so much inwards that its in margin was hidden by the caruncle; contraction of the pupils; extreme amb opia, fingers being counted with difficulty at one foot; and concentric contrac of the visual fields. The refraction determined by the ophthalmoscope slightly myopic; the optic disks were normal; perception of colour, whe could be tested, was intact. The girl stated that two years previously she suffered a similar attack, lasting nine months, and associated with convulsi While under treatment, and without known exciting cause, she was seized s ral times with convulsions in the form of a marked opisthotonos, with al complete loss of consciousness. The symptoms above described underw remarkable variations as regards their intensity within very short periods of ti sleeplessness intensified them, while sleep, procured if necessary by morp relieved them. The acuity of vision especially varied greatly even during amination, being rapidly lessened by the effort to use the eyes. Recovery, or less complete, occurred several times, only to be soon followed by a recurr of all the symptoms. With regard to the strabismus, it is noteworthy that, the condition was at its worst, both eyes were turned strongly downwards inwards, and had lost all power of movement upwards and outwards. R ence is made to other cases of a somewhat similar character. [A case c resembling this one in certain points is recorded in the *Royal London Op mic Hospital Reports*, vol. ix. page 27.]—*Lond. Med. Record*, April 15,

—

Method of Correcting Sinking of the Nose.

At a meeting of the Imperial and Royal Medical Society of Vienna (*Me ische Jahrbucher*, January, 1880), Dr. MIKULICZ showed a patient on wh had performed rhinoplasty, and made some remarks on the subject. He that the problem of making an artificial support to the nose, which was the difficult part of rhinoplasty, had been attempted to be solved by surgeo very various methods. Dieffenbach and Rust tried a support made of a pl gol this, however, produced suppuration by its pressure, and soon had removed. Leisrink used a support made of amber in the case of a child years old, allowing the parts to heal over it. There is no information, how as to the permanency of the success, or as to the state of affairs during the gr of the child. Other methods have been tried by Dieffenbach, Langen Busch, Volkmann, Thiersch, etc. The idea of Dr. Mikulicz was to constru nasal support which might be inserted and removed at will, just as is done artificial sets of teeth and artificial eyes, which do not produce ulceration if are frequently changed and kept clean. He constructed for this purpose a port consisting of two symmetrical bent pieces of copper wire covered with canized caoutchouc. The two first portions lie parallel to each other under bridge of the nose, and raise it up. The two middle pieces lie like the sid a steep roof, and occupy a position nearly corresponding to the lateral bord the pyriform aperture. The posterior piece is slightly curved, and rests ag the lower border of the aperture. The apparatus can be introduced and remo by means of a small forceps, and, when in the nose, is not seen. It causes trouble, and the wearer soon becomes accustomed to the sense of a foreign b which it produces. The patient, who was exhibited to the society, was a wo aged 27. She had worn the apparatus sixteen days, and had acquired consi able facility in its management.—*London Med. Record*, March 15, 1880.

Complete Closure of the Larynx after Diphtheria.

ERK relates the following case (*Wiener Medizinische Wochenschrift,*
79). The patient, a boy 7 years old, had had an attack of diphtheria
previously, for which tracheotomy had been performed. Three weeks
peration the tracheal canula (an unfenestrated one) had been removed,
d immediately on account of difficulty of breathing. The child had
tinually until he came under the care of Professor Stoerk. He was
speak aloud. A *cul-de-sac* could be seen with the aid of the laryn-
just below the true vocal cords which moved freely, but their move-
ot accompanied by phonation. There was no appearance of mucus,
rally makes its way up, even in very high degrees of laryngeal steno-
ror introduced through the tracheal wound demonstrated a complete
between the larynx and trachea. The mucous surfaces, soon after
flammation, would seem to have grown together; the unfenestrated
ng off the passage of air and secretions which might have prevented
t. The adherent tissues were divided, and the parts dilated. After
of the tracheal wound the boy regained his voice.—*Lond. Med.*
ril 15, 1880.

The Removal of the Pharynx, Larynx, etc.

ation has lately been performed successfully by Professor CASELLI,
(*Il Morgagni*, September, 1879). The case was one of epithelioma
e of the glottis. The first step in the operation was to perform tra-
nd then insert Trendelenburg's canula; the next to lay bare the
solate it. This was then removed by means of the galvano-cautery,
the cricoid cartilage, and the pharynx as high up as the tonsils.
one was next divided at its middle, and the base of the tongue am-
ther with the soft palate, the remaining portion of pharynx up to
the posterior nares, and both tonsils. The operation lasted three
ut little blood was lost, owing to the constant use of the galvano-
he dressing was antiseptic, and the upper two-thirds only of the
ht together. An œsophageal sound and the canula were both main-
sition. At the time of writing, *i. e.*, fifty-three hours after the ope-
atient had completely recovered from the shock, and promised well.
ion proved eventually successful, and Professor Caselli has been able
artificial œsophagus and larynx.)—*London Med. Record*, April 15,

Case of Resection of the Anterior Wall of the Thorax.

UMAN reports (*Deutsche Zeitschrift für Chirurgie*, Band xii. Heft
llowing case from the clinique of Prof. Fischer, of Breslau. The
oman aged 48, had, about four years before her admission, noticed,
time, a small fixed tumour over the fourth rib, and in a line with the
he left side. After it had grown slowly during two years and a half,
ed to increase rapidly in size, and extended into the left armpit.
of this swelling was attended with but slight and occasional pains.
een by Professor Fischer in June, 1878, she presented a tumour occu-
st the whole of the anterior wall of the left side of the thorax.
the growth extended to the scapular line, and into the left axilla, pre-
plete adduction of the arm. Upwards it reached as far as the clavicle,
to the seventh rib, and internally to the left margin of the sternum. It
ixed at its base, and projected forwards to a considerable distance in

front of the level of the right nipple. Its anterior surface was studded by h
small, and rounded growths. The integument over the tumour was mov
quite sound, and traversed by numerous enlarged veins of a dark-blue co
The general health of the patient was good. As the rapidly growing tu
would speedily have compressed the nerves and vessels of the left upper extre
and as the mass by its weight and enormous size prevented the patient f
working for her support, Professor Fischer decided to extirpate the disease.
operation was commenced under the assumption that the costal pleura m
have been readily stripped off from the base of the tumour, and from the
eased portions of the ribs. It was found, however, in the course of the op
tion that the growth extended for some distance into the left cavity of the c
and that it was in close connection with the costal pleura. A vertical inci
having been made in the integument, the superficial portions of the growth
cut away, and portions of the third and next three inferior ribs separated
removed. The deep and pleural portions of the tumour were then diss
away, and in the course of this stage of the operation the left thoracic cavity
freely laid open, and the left lung and the surface of the pericardium fully
posed. Every bleeding vessel was at once secured, and the patient lost but
blood during the operation. A large drainage-tube having been carried
the thoracic cavity, and another along the more superficial parts of the wo
the edges of the skin were brought together, and fixed by sutures. The s
of the chest had been carefully disinfected before the operation, and the
was afterwards covered by Lister's dressing. The carbolic acid spray w
used during the operation, nor on subsequent change of dressing. The re
the case proves, Professor Fischer states, that the use of the spray is
essential adjunct to antiseptic surgery. The patient suffered much at first i
sequence of collapse of the left lung, but afterwards progressed favourably.
wound was quite closed on the fortieth day. The extirpated tumour w
nine pounds and a half. On examination it was found to be an enchon
that had ossified at its base, and had undergone colloid degeneration at its
ficial parts. Portions of the third and three following ribs had been involv
the growth. The portions of the fourth and fifth ribs that were removed
ured each about four inches and a quarter in length; those of the third and
ribs each about half this length. In a report on the condition of the p
after her recovery, Dr. Szuman states that there was perfect movement
left arm, and that the pectoralis major, which had been previously attach
the tumour, had now become attached to the remaining portions of the
ribs, and performed its functions quite well. The portion of integument
had been so much stretched over the surface of the tumour was drawn in
between the left lung and the wall of the thorax, and was firmly adherent t
pleura pulmonalis. The left lung, though collapsed, was not atelectatic,
when the patient coughed, it occupied the whole of the left thoracic cavity.
defect in the anterior wall of the thorax corresponded to the size of an inf
head; the heart, covered only by pericardium and a portion of integument
herent to the sac, could be seen pulsating in the middle of the defect, and
contractions of the left auricle and ventricle could be distinctly seen and fel

Statistics of Cancer of the Breast.

Dr. J. Oldekop has published, in the twenty-fourth volume, of the *Ar*
für Klinische Chirurgie, a statistical summary of all the cases of mammary
cer occurring in Professor Esmarch's hospital and private practice from 185
1878. With regard to age, most of the cases occurred between the forty-ei

years; in 123 patients the age did not exceed 48; in 71, it was be-
nd 58; and, in 35, the age was 59 and upwards. In 21 cases, there
iculars as regards age. Women who had borne more than six chil-
hed the greatest contingent, and next came those who had no children.
nine in this category, against 103 who had given birth to children.
in which the information could be obtained, 15 had not, and 46 had,
ir children. In 36 cases, mastitis had preceded; but in only 9 was it
with certainty that the cancer had its starting-point in an induration
remaining after mastitis. In three cases, there had been contusion
asation; the extravasation, after some years, forming the centre of
owth. In two cases, the seat of the primary nodule was a part of the
h had been for some years pressed on by the string of the corset; in
was a part that was often pressed on by a yoke. In 126 cases, the
was diseased, in 102 the left. The outer and upper part of the
most frequently first affected; and this is ascribed by Dr. Oldekop
er liability of this part to injury. In three cases the cancer was pre-
ronic eczema of the breast. Circumstances indicating the influence
y tendency were noticed in eleven cases. The average duration of
e commencement of the disease was, in the cases not operated on,
; in those operated on, 38.1 months. On 225 patients, 287 opera-
erformed. Of these 225, there died in the hospital 28; viz., 5 from
e cancer, and 23 from the operation; among these were 14 cases of
tion of the mamma with removal of the axillary glands. With re-
influence of treatment on the mortality and on the time required for
Oldekop's statistics show no marked difference between the anti-
ne non-antiseptic methods; he remarks, however, that erysipelas has
quent in Dr. Esmarch's practice since the introduction of the anti-
d. The time after the operation at which the disease returned is
cases. In 14 cases it immediately followed the operation; in 15, it
ithin the first month; in 23, within three months; in 15, within more
nd less than six months; in 13, from the seventh to the ninth month;
the tenth to the twelfth month; in 9, from the thirteenth to the eigh-
h; and in 8, within three years. In one doubtful case the interval
ve exceeded three years. At the time of the report, 44 of the women
d free from a return of the disease; of these, six had died of inter-
ases; three within three years since the operation, and three after
In 15, the time during which they had remained free from relapse
hree years; and, assuming three years as the extreme time for a
e disease, 26 could be regarded as definitely cured; in 10 of these,
ed axillary glands had been removed with the mammary cancer.
es a second operation was necessary. Although the number of cases
omplete cure followed the operation is not large, Dr. Oldekop regards
ntly encouraging to induce surgeons to operate early, and thus in-
nance of a good result.—*British Med. Journal*, April 17, 1880.

On the Treatment of Gonorrhœa.

(Concluded from last Number, page 300.)

ct Treatment of Gonorrhœa.—It often happens that local means do
ffice in the treatment of chronic gonorrhœa, and then we have to sup-
se by the use of medicinal substances acting through the digestive
Most of the substances thus employed, when introduced into the di-
ns, are excreted into the urine, and in this way act curatively on the

gonorrhœa. Amongst those which are especially active in this way may be mentioned the balsams of copaiba and Peru, cubeb pepper, oil of turpentine, gurian balsam, and matico. Recently the kava-kava or ava-ava has been strongly recommended for the treatment of acute and chronic gonorrhœa, but it has not succeeded in Prof. ZEISSL'S hands. On the other hand, preparations of iron have proved very efficacious. As to the question, when should these substances be commenced? a general rule can scarcely be laid down. In hospital practice, when the patient can be closely watched, recourse to them need be had but comparatively rarely; but in private practice the case is different. Patients wishing to pursue their occupation often neglect the injections for a whole day, or they perform them so unskilfully that not a drop of the fluid enters the urethra. Under such circumstances we must have recourse to internal medicines. But it is also often observed that after continuing injections for days the discharge does not diminish, and continues very thin; while after the employment of some of the above-named substances for some time it lessens in quantity and acquires consistence. The opinion is frequently expressed that the employment of these resinous substances, especially copaiba, may give rise to albuminuria, but Prof. Zeissl has never met with an instance in the thousands of cases which he has treated by resinous substances. The opinion has indeed arisen through ignorance of chemistry. It has been observed that, on the addition of nitric acid to the urine of a person who has employed these medicines, a white precipitate is produced. But this precipitate is again dissolved by boiling, which is not the case with a precipitate of albumen produced by nitric acid. Or if we boil the urine, slightly acidulated with acetic acid, or apply Hoppe-Seyler's sensitive test, no trace of albumen is seen to exist. Weikart's and Prof. Zeissl's experiments have shown that it is not the ethereal oil but uric acid that is precipitated by the nitric acid. These resinous bodies sometimes give rise to a form of urticaria (U. balsamica), but this soon disappears on discontinuing the remedy. The following formulæ are recommended by Prof. Zeissl: 1. Matico in capsules (fifteen a day); 2. Ethereal extract of cubebs and spirit of turpentine, equal parts, made into a pill-mass with magnesia usta, of which twenty-four pills weighing each 35 centigrammes should be taken daily; 3. Copaiba 15 or 20 drops three times a day in capsules; 4. White wax 5 grammes melted by a gentle heat, balsam copaiba 15 grammes, magnesia 9 grammes, to make a pill-mass, eight pills of 30 centigrammes three times a day. Balsam of Peru, turpentine, and similar substances may be given in the same way. 5. Of preparations of iron, a teaspoonful may be given five times a day of a mixture containing 1½ parts of the liquor ferri, 150 of water, and 25 of syrup of raspberries; or 1 gramme of saccharated carbonate rubbed up with 3 grammes of sugar may be divided into ten powders, of which three are given daily. Prof. Zeissl has given a fair trial to an infusion of the kava-kava root, which is in fact the *Piper methysticum*, but has found it completely useless.

As already observed, not unfrequently neither the direct nor indirect treatment succeeds in effecting a cure, and then we have to resort to the use of bougies and sounds; the cause of this prolonged duration of the affection being the implication of the prostate. As Thompson remarks, most practitioners in treating gonorrhœa pay too little attention to the disease of the prostate which may be consequent upon this. Prostatitis in its acute form indeed is rarely overlooked, on account of the severe suffering that attends it. Very severe pains are felt in the perineal region, especially on walking or when sitting, while a sensation is perceived as if the rectum were obstructed by a foreign body, and the passage of the feces and of the urine is rendered difficult. On examination by the rectum the prostate is found swollen and very sensitive; and if the inflammation goes ked, in from the eighth to the twelfth day suppuration takes place. the abscess so formed discharges itself, and usually during the ejacula-quent upon a lascivious dream. If, however, there is a violent pain fever and evident fluctuation, an incision must be made through the r the discharge of the pus; but although Prof. Zeissl has had many hich this operation has been performed with the best results, yet he has recourse to it except in the extremest need, as there is always danger of g process being impeded by the passage of the feces. In very rare prostatic abscess is discharged through the perineum, and a urinary then be the result.

inflammation is, however, a far more frequent occurrence than acute The symptoms in both forms are similar, except that the accompany-action is more of the synochal type in acute, and more of the inter-pe in chronic prostatitis. The patients complain of a dull sensation in um, especially when standing or walking, as also of pains in the sacral along the posterior parts of the thighs. The urine contains epithelial ed with pus corpuscles and prostatic secretion. On examination by the e prostate is seldom found enlarged, but it is more or less sensitive to ssure. A patient in this condition may employ injections, and even h contain a pulverulent deposit, for months, and yet not be completely s already stated, such a case must be treated by the elastic bougie, or by means of a solid instrument. Choosing one corresponding to the orifice of the urethra, we find, supposing there be no stricture present, n pass it without obstacle on to the prostatic portion of the urethra. ere, we are unable to pass into the bladder unless we employ consider-—which is always to be avoided. An instrument of three or four num-ill pass without difficulty into the bladder, causing during its passage e prostatic portion not only the stabbing pain always felt on gliding aput gallinaginis; but also a severe burning sensation along the entire ortion. After the first introduction of a solid instrument there usually the urethra one or more drops of a viscid fluid mingled with blood-l which is nothing else than the prostatic secretion combined with a l derived from the hyperæmic prostate. An instrument must be passed everal days, and after the second or third introduction a larger one will into the bladder. One rule should be observed in cases in which the not effected easily over the prostate into the bladder—viz., to greatly e instrument, when it will easily slip into the bladder. It is always for beginners to employ a metallic catheter rather than a sound, as it of great satisfaction to them to see the urine flow from the bladder, emain in painful doubt, during the four or five minutes the instrument emain, whether it is actually in the bladder or has made a false passage. ocedure be continued for some days, the patient observes, sometimes ut much oftener at night during sleep, that there is a considerable quan-iscous fluid discharged from the urethra, unaccompanied by lascivious erections, and which leaves a sharply defined gray spot on his linen. ign that the chronic prostatitis has come to an end. After each intro-f the instrument either some water or a very dilute solution of a metal-ould be injected, in order to wash away any of the oil which may have etached from the sound, as this induces a rather sharp burning sensation thra.

s mode of treatment a chronic gonorrhœa which has often persisted for cured in a comparatively short time. The secretion which appears at h of the urethra in this affection arises not only from the small diseased spots of the urethra still uncovered by epithelium, but also at least in part from the prostate. By the introduction of the sound a sharper irritation is excited in the portions of the mucous membrane of the urethra suffering from chronic catarrh, and the moderately swollen prostate is at the same time submitted to compression, and in this way the symptoms which characterize chronic urethral catarrh are brought to an end. In Prof. Zeissl's opinion, chronic gonorrhœa never exists without a moderate tumefaction of the prostate, which, however, is not always perceptible to the sense of touch. In confirmation of the correctness of this view, it is to be observed that individuals who have very frequently had gonorrhœa, or in whom gonorrhœa has persisted for a long period, are the subjects of a considerable enlargement of the prostate in their thirty-fifth year, and often even younger. This hypertrophy is the result of the hyperæmic condition which the prostatic portion of the urethra and the prostate itself are in during the existence of chronic gonorrhœa; and we all know that an organ to which for a long time a very large supply of blood is conveyed becomes hypertrophied.—*Medical Times and Gazette*, Feb. 21, 1880.

Urethro-perineal Inflammation and Abscess due to Gonorrhœa.

M. Mauriac (*Gazette des Hôpitaux*, Feb. 17, 1880) remarks that peri-urethral abscesses, when situated in the penile portion, appear as hard red painful lumps, and may be met with anywhere between the fossa navicularis and the bulb. They sometimes cause considerable peripheral œdema, are readily diagnosed, and run a rapid course. To avoid fistulæ, an early opening should be made. Abscesses around the deeper urethra are much more serious than those just mentioned. They generally begin in Cowper's glands or the prostate, and, if care be not taken, may be mistaken for abscesses connected with stricture, or for superficial abscesses unconnected with the urethra at all. The inflammation of the urethra may extend to all the glands in connection with it, from the simple acini to the conglomerate glands of Cowper and the prostate. Acute inflammation of Cowper's glands nearly always ends in suppuration. The most frequent cause is gonorrhœa, when it has lasted from twenty to twenty-five days. Balsamic remedies and injections do not appear to have any influence in causing inflammation of these glands; but it sometimes follows immoderate sexual indulgence, or a blow on the perineum, and may also arise from the introduction of too large an instrument into the urethra, or from the retention of a bougie. One gland only is usually affected, and the left more often than the right. It is rare for both glands to be attacked at the same time. The abscess may point externally or internally; sometimes it opens both through the perineum and into the urethra. Suppuration occurs from the fifth to the tenth day, and in eight or ten days afterwards cicatrization is usually complete. As a general rule, if the urethra be free from stricture, any inflammatory swelling deep in the perineum at its anterior portion is connected with Cowper's glands; while abscesses in the posterior part of the perineum are connected either with a lesion of the anus or of the prostate. Simple perineal abscesses may, however, occur, and when not seen early, there may be some difficulty in the diagnosis; such abscesses, however, quickly close after incision, and urinary infiltration never takes place. The treatment of inflammation of Cowper's glands, before suppuration has taken place, consists in the application of leeches, blue ointment, and extract of belladonna, poultices, prolonged baths, and rest. Saline purgatives should also be given. As soon as fluctuation can be made out, or even before it is well marked, the swelling should be incised. Inflammation and abscess of the prostate are also described by the author.—*London Med. Record*, April 15, 1880.

Syphilitic Ulceration of the Bladder.

paper (*Vierteljahresschrift für Dermatol. und Syphilis*, 1879, Heft sch does not bring forward any example of his own, but gives an account es, which comprise all the satisfactory instances he has been able to find during the last four hundred years. The six cases include one by Moro by Ricord, one by Virchow, one by Vidal (de Cassis), and one by ky. Proksch sums up the information afforded by a study of these cases s. Ulceration of the bladder, sometimes, though rarely, happens in The age of the patient has no influence on the occurrence of the ulcers, ve been found in patients from four to eighty-four years of age. There men, one woman, and one child. Vidal's patient was of vigorous con- Tarnowsky's patient was, on the contrary, weakly. The ulcers of the ccurred in four cases with, and in two without, ulcers of the urethra. tion came on in Ricord's and Vidal's cases about the beginning of con- manifestations; in Virchow's and Tarnowsky's cases, other syphilitic d gone before. In Ricord's cases, the ulcers of the bladder and urethra only secondary signs present. The number of ulcers varied between eleven; but in two cases, the ulceration was diffused. The size of varied from a lentil to a kreuzer. The ulcers were either superfinowsky), or penetrated the mucous tissue (Ricord). In Vidal's case, f the bladder was perforated. The termination of the cases was either the ulcers (as in Virchow's case, and to some extent in one of Ricord's death from perforation of the bladder. What share the non-perforating l in the fatal result, cannot be proved. The symptoms of ulceration e would vary according to the seat, number, size, and depth of the nt cystitis and catarrh of the bladder, varying in degree in different cases, bably be present.—*Lond. Med. Record*, April 15, 1880.

Use of the Catgut Ligature in Aneurism.

Tapia gives (*El Genio Medico-Quirurgico*, No. 1275) a series of s of aneurism successfully treated by ligature of the arteries involved, ptic method having been employed in all three. The first occurred in male, aged 31, and involved the axillary artery in its first stage. with iodine and digitalis internally, were apparently giving satisfactory hen unexpectedly the sac of the aneurism burst, and the patient's arm ecame enormously swollen. In these circumstances it was necessary to cure the vessel, which was done under strictly antiseptic precautions with tisfactory result. The highest temperature was on the night after the , when the centigrade thermometer showed 40 deg. (104° Fahr.). The ealed without any appreciable suppuration, and the patient was dis- cured within six weeks. In the second case, a large axillary aneurism ted ligature of the subclavian. The artery was exposed at a depth of ntimetres, and inclosed in a loop of catgut which was left buried in the ausing not the slightest symptom of irritation. The treatment, which septic throughout, was continued for a month, and resulted in complete The third case was one of popliteal aneurism, in which ligature of the rtery was successfully performed, after pressure by means of weights had The author considers these cases as affording strong arguments in favour ntiseptic ligature, which in his opinion diminishes very considerably the secondary hemorrhage and other accidents. Most of the substances used as ligatures act as foreign bodies, and set up irritation and inflammation in the vascular walls with eventually perforation and hemorrhag Against this particular danger, the catgut ligature appears to be a complete sa guard.—*Lond. Med. Record*, April 15, 1880.

Ligature of the Carotid for Aneurism of the Innominate Artery.

The case reported by M. Sabatier (in the *Lyon Médical*, Oct. 5, 12, 187 from the treatise of M. Desgranges, is worth recording as a fresh instance of distal operation in (presumed) innominate aneurism, and to some extent of good effect, though its value is seriously diminished by the absence of any *p mortem* examination.

The symptoms are given in detail, but we do not judge it necessary to rep duce them here. It is sufficient to say that they were such as seem to justify diagnosis of aneurism of the innominate artery—though, as far as the pres reporter can see, there is nothing to show that the aorta was not also affect nor even to render it absolutely impossible that the aneurism might not h been purely aortic, as it was in Mr. Christopher Heath's well-known case. that is said on this head is, that the diagnosis of aortic aneurism was excluded account of the development of the tumour so exclusively on the right side of thorax. But Mr. Heath's and other cases show that this sign is not by means certain. The right carotid artery was tied on February 8, 1878. T was followed at first by a considerable diminution of the pulsation and size the tumour, but in a few days the parts around the wound became inflamed œdematous, and then the tumour began to grow in size—though the pulsa continued more feeble, and the rheumatic pains of which the patient had c plained were much easier; and in this condition he remained till he quitted hospital, after a stay of three months. At that time, his general condition one of much general weakness. He survived his discharge from the hos about nine months, and died from a cause which seemed quite unconnected the aneurism—viz , from bronchitis contracted during a period of very weather. He had been under medical observation, and the aneurism had b going on so well—contracting and becoming harder, as he recovered his gen health—that hopes were entertained of a complete cure. It was noticed t during his fatal illness, though the cough was very violent, it did not in the l affect the size of the tumour. As stated above, no *post-mortem* examinat could be obtained.

In the remarks which the narrator of the case has appended, he discu chiefly the operation of Brasdor (or Wardrop), and mainly addresses himsel the question whether it is desirable to tie the carotid alone, the subclavian alone both arteries simultaneously. He resolves this question in favour of the ligatur the carotid only, for the same reason which has led the present reporter to inclin the same conclusion; viz., because it is the treatment which allows a more log explanation of its action on the sac than the ligature of the subclavian does, asmuch as the coagulation of blood which usually occurs in the whole car artery after successful ligature may be expected to extend into the portion of sac through which the blood going to the neck has been circulating. Strang enough M. Sabatier believes that this consideration has been hitherto overlook He says, "Lastly, and this is a circumstance to which the authorities do allude, the portion of the carotid below the ligature will be obliterated in all extent, and the coagula reaching the inner wall of the sac will become the ori of new coagulation, in virtue of the old adage that fibrin produces fibrin." E dently, M. Sabatier has never read the *Lectures on Aneurism*, delivered, by present writer, at the Royal College of Surgeons, and published in French *zette des Hôpitaux*, in which this fact is dwelt upon at a very great length. s M. Sabatier had the opportunity of perusing the very interesting and unt cases of double distal ligature which Mr. Barwell has recently pub- These cases do unquestionably tend to restore our confidence in that , and to predispose us to admit that the ligature of the third part of the ian may have some curative influence, however difficult it may be to for it theoretically. In one of Mr. Barwell's cases, in which the patient me months after the operation, of bronchitis, very much as M. Des- 's patient did, Mr. Barwell states (*Med.-Chir. Trans.*, vol. lxi. p. 31) e whole of the subclavian artery was obliterated; and in a second case vol. lxii. p. 395) where the patient was still alive, he believes that the esult was obtained. The latter case, however, is obviously inconclusive; he former the *post-mortem* examination was confessedly somewhat imper- d the preparation did not show any definite anatomical proof of a result etrically opposed to all our other experience of the phenomena of the l circulation after ligature, since, beyond all doubt, the ordinary and fect of tying the third part of the subclavian would be, not to obliterate, nsure the patency of, the first part, through which the circulation for the st pass; and if the carotid were also tied, one would expect that the cir- through the thyroid axis would be greatly increased, and, therefore, the t of the subclavian proportionately dilated. Nevertheless, no one is epared than the present writer to admit that theory must bow to expe- and if the results of the latter are so decisively in favour of the simul- double ligature as Mr. Barwell's experience seems to indicate, we must ared to adopt it. Meanwhile, such cases as this of M. Desgranges' are , as showing what may be effected by the ligature of the carotid only, it is a great pity that no necropsy was obtained.

uggestion that M. Sabatier makes is worth bearing in mind; whether, in herwise hopeless, it might not be worth while to try the effect of simply g the tumour by dissection, without tying any vessel; recollecting the own case under the care of Porter, where consolidation and apparent lowed in a subclavian aneurism, though the innominate artery, when ex- vas so diseased that the surgeon did not venture to put a ligature on it.— *Med. Record*, April 15, 1880.

Case of Arterio-venous Aneurism Cured by Pressure.

NI relates (*Bulletino delle Scienze Mediche*, January, 1880) an interest- of traumatic aneurism of the common carotid, involving also the internal vein, in which a complete cure was effected by steady long-continued . The patient had received a stiletto-wound in the left side of the neck; en first seen, the tissues around the seat of injury were enormously swollen ltrated with blood. The diagnosis admitted of no doubt, as all the signs io-venous aneurism were well marked. Treatment by cold, absolute rest, italis, having failed, and the statistics of the operations hitherto performed cure of arterio-venous aneurism in this situation being very unfavourable, nor determined to have recourse to direct pressure. He employed for this Rizzoli's horse-shoe compressor, which he considers to offer certain ad- s over Signoroni's, one being that the pads are movable and can be applied direction. After a few days of this treatment, the improvement was so that the patient anxiously seconded the efforts of the surgeon, and kept lar pressure by means of the screws attached to the pads, which he mani- l himself. After five weeks he left the hospital much improved, though eurism still existed. The author therefore adapted a semicircular pad with two cushions to the part, and directed the patient to wear the instrument continuously. The result was most satisfactory. When next seen, all traces of the tumour had disappeared, save a small hard lump of the size of a hazel-nut, which was probably the obliterated jugular vein. The steps in the process of cure had probably been (1) closure of communication between the vein and artery; (2) obliteration of the vein, by which the aneurism became a simple arterial one, (3) which eventually became consolidated and absorbed.—*London Med. Record*, April 15, 1880.

Nerve-Stretching.

Amboni records (*Annali Univ. de Medicina e Chirurgia*, Jan. 1880) a cas of obstinate neuralgia of the upper arm with contraction of the forearm, and pai radiating over the whole upper half of the left side, successfully treated by stretc ing the nerve-trunks of the brachial plexus. The patient, a female, was 39 yea of age, and the affection had lasted over a year, having commenced shortly aft an extensive abscess in the axilla had ceased to discharge. Every method treatment had failed to give relief, and as a last resource the author determin to cut down on the brachial plexus, and expose the nerves forming it. The op ration was one of considerable difficulty, and lasted over an hour. Twenty lig tures were applied, four of which were on veins. The connective tissue arou the nerves was carefully removed, and their trunks exposed and stretched; drainage-tube was then inserted, and the wound closed with sutures. The op ration was scarcely finished before its good effects became evident. The patie could at once move the fingers and forearm, and was quite free from all pai The wound healed without any bad symptom; and, up to the time of writi seventy-four days after the operation, there has been no return of the neural pains.—*London Med. Record*, April 15, 1880.

Sutural Junction of Wounded Nerves.

In a paper read before the Berlin Medical Society on January 14th of t present year, and published in the *Berliner Klinische Wochenschrift*, No. Baron von Langenbeck gives the details of a case, the subject of which, labourer aged 31, had received severe injuries through the fall of a ceiling. Th patient, when first seen, presented a large scalp-wound in the frontal region, an was unable to stand in consequence of an injury, probably fracture, to the lumb portion of the spine. The integument over the outer surface of the right arm i its lower half was much bruised, and there was complete paralysis of the exte sors of the hand and fingers on the same side, with loss of sensation over th back of the hand. The bruised portion of integument above the elbow subse quently sloughed. At the end of the second month the patient had recovered from the more severe injuries, but still remained under treatment in consequence of the following condition of the right upper extremity. The bruised and ne crosed portion of integument had been replaced by a tender cicatrix, which was situated over the spot where the median nerve passes between the triceps and brachialis anticus muscles, before taking its course along the forearm. The extensor muscles of the hand and fingers were completely paralyzed, and the affected muscles failed to react both to the constant and the induced currents. There was loss of sensibility in the skin over the back of the hand and forearm. This condition was regarded as the result of a solution of continuity in the median nerve, produced at the time of the separation of the sloughing portion of skin from the outer surface of the arm. An incision having been made through the cicatrix, the divided nerve was exposed, and its two extremities, separated from each an interval of about two centimetres, were dissected out from the sur- g cicatricial tissue, trimmed with scissors, and then brought together by suture. Considerable difficulty was experienced in bringing the free the divided nerve into close contact, and fears were entertained that the ould speedily tear itself away. On the twentieth day, however, after aling of the wound, which had been dressed antiseptically, there was reaction of the extensor muscles to the induced current, and in the course days the patient was able to extend his fingers. The patient, when d at the end of the seventh week, could move his fingers very freely, extend his hand, though he could not raise it beyond the horizontal In his remarks on this case, Dr. von Langenbeck states that the fact led nerve, when joined by suture, healing by primary union and rapidly g its functions, has been proved beyond doubt by the recent experiments on fowls. According to this observer, the restoration of conduction in ed nerve depends on the formation of an intermediate substance consist- anulation tissue, which is deposited in small quantity when the perineum intact, and in abundance when a completely divided nerve has been suture. In this intermediate substance Gluck found, on the fourth day ion of a large nerve, large granular spindle-cells, which are arranged in run together at their elongated extremities. These spindle-cells, which gards as glanglion-cells, as they are darkly stained by osmic acid, are l into fibres which connect the axis-cylinders at the extremities of the erve, and their protoplasm becomes differentiated into axis-cylinders llary substance. Clinical observations on the results of suture of nerves ave not hitherto been so conclusive as the experience of trials made on In the former, the suture was almost always applied to a sensory nerve, etermination of such results as may be thus attained must necessarily ifficult and doubtful. It is not easy to make out to what extent the r of the region supplied by the wounded and sutured nerve has been and moreover, there is likely to be deception on the part of the patient. or states that, in most of the cases hitherto recorded of sutural junction , the required results have been doubtful or altogether wanting. The f sutural junction should be more satisfactorily determined by dealing otor nerve, because in such case the surgeon is able, by the use of the current, to make out the extent of the paralysis caused by the injury rve, and also the extent to which the functions of the wounded nerve n restored after the application of the suture. Von Langenbeck's case re of value as proving that, by bringing together the ends of a divided h a suture, union by primary intention may take place, and the function unk be restored.

the author states, is the third reported case of secondary suture of the erve. In one case reported by Letiévant, sutural junction of a wounded nerve was attempted, but without success, two years and a half after the f injury. In the remaining instance, Esmarch applied a suture to the ve sixteen months after its division by an extensive wound. In this operation was followed by partial success. The best material for the r a wounded nerve trunk the author believes to be catgut. This causes ation than silk or wire, does not need removal, and does not interfere process of primary union. This case differs from other cases of divided unk hitherto reported, in the fact that no swelling was observed at either parated extremities of the nerve. The author attributes this to the fact median nerve had not been divided by sudden and violent injury, but dually given way during the separation of a slough. Another point of interest in this case is the fact that regeneration of the nerve-tissue and restoration of the function of the median nerve so speedily followed the operation, although, as was found on microscopical examination, no nerve-elements existed in the small portions removed from the free ends of the nerve by scissors. I all previously recorded cases of suture of nerves, the centripetal propagation o impression was the first to be renewed. In Dr. von Langenbeck's case the opposite result was observed, the anæsthesia of the integument on the dorsum of th hand having persisted long after the movements of the extensor muscles ha been almostly completely restored.—*London Med. Record*, April 15, 1880.

Modified Amputation of the Foot.

In a thesis upon Chopart's amputation of the foot, Dr. Duchamp,[1] after a carefu *résumé* of the bibliography of the subject, gives in the appendix the mode procedure suggested by Dr. Leon Tripier, of Lyons. This, however, cannot b called a modification of Chopart's amputation, as the author implies. It is rath a modification of the subastragalar, as the incisions are almost identical. B by whatever name it may be called, it is an operation well worthy of consideration, in cases of injury or disease, when the anterior portion of the foot has to b sacrificed.

Chopart's amputation has been perhaps universally looked upon with conside able disfavour, on account of the painful stump and tilting of the heel whi follow sooner or later in many cases; and the cause of this is no doubt primar the loss of the front half of the arch of the foot—a loss which it is extremely di cult to replace by mechanical means. The immediate cause does not appear be so much any contraction of the tendo Achillis as of deeper tendons, and esp cially ligamentous structures; the latter of which are, according to Max Sche dragged upon by the tendency to backward slipping of the calcaneum. Exa ining the static conditions of the foot, M. Leon Tripier noticed that a horizo plane, on a level with the sustentaculum tali, would divide the calcaneum right angles to the axis of the limb, and expose a large surface of support; a he proposed, therefore, an operation after the following plan, in place of t usual method of Chopart's amputation.

The flaps are to be marked out by two elliptical lines, the first extending fro the outer part of the tendo Achillis at its insertion, then passing two finge breadths below the outer malleolus, and the same distance above the tuberosit of the fifth metatarsal bone, to end on the inner side of the extensor propri pollicis tendon, opposite the posterior extremity of the first metatarsal bon This is to be the dorsal flap. The plantar marking extends from the last-name point downwards and forwards to about an inch in front of the base of the fir metatarsal bone, in the sole of the foot, then obliquely across the bases of th metatarsals to the outer side of the foot, and so to the starting-point at the out side of the tendo Achillis.

The stages of the operation M. Tripier divides into four: 1. Section of th skin; 2. Division of the subcutaneous tissues; 3. Division of muscles an tendons; 4. Disarticulation and section of the bone. With reference to th division of the muscles and tendons, he divides first the dorsal tendons along th line of incision, then the plantar muscles, similarly, dissecting the latter flap back by keeping close to the bones. He then disarticulates as for Chopart's amputation. Then he detaches the periosteum from the calcaneum, as high up as the

---

[1] Etude sur l'Amputation de Chopart. Par le Dr. S. Duchamp. Paris, Baillière et Fils. 1879.

he sustentaculum, and saws through the bone horizontally from the inner
ediately below that process. This being done, he rounds off the pro-
nterior angle of the bone. The two plantar arteries and the dorsalis
e to be twisted or tied, and he advises the operator to seek the posterior
rve in the inner flap and remove it as high as possible, so as to avoid
nt neuroma, which proves so troublesome after Chopart's amputation.
refully closing the wound, and placing a drainage-tube through it, he
zes the stump by means of a silicate bandage, which extends to the knee.
cision, according to the author, resembles the inner plantar flap adopted
Roux in tibio-tarsal disarticulation, but the whole operation appears to
a modified and much improved subastragalar amputation. The hori-
ction of the calcaneum has a marked advantage over the subastragalar;
only preserves a greater length of limb, but places the stump in better
ndition. The astragalus has its lower surface oblique, being directed
ds and forwards, and there would therefore follow after a subastragalar
on a tilting of the astragalus and a dragging upon the ligaments of the
l articulation. Besides this, the base of support is larger after section
lcaneum, whence greater solidity in such a case. Lastly, after subas-
amputation the astragalus is no longer connected with muscles and
but with the section of the calcaneum the tendo Achillis is preserved,
ateral tendons being in contact with the detached periosteum there is as
edom of movement as after Chopart's amputation, without the incon-
of that operation, seeing that the equilibrium of the stump is secured.
ew operation has a further advantage over Chopart's in requiring less
ap, and also in making it possible for the operator to see the condition
caneum; and this is undoubtedly of considerable importance, especially
equiring amputation for disease, although certainly the astragalus is
cted earlier than the larger bone. If the calcaneum be too much dis-
en a subastragalar or higher amputation can be immediately performed.
or makes the following experiment upon the dead subject. If the cut
the calcaneum be applied to the horziontal plane of a table, and strong
ressure be applied on the tibia from above, no movement is seen at the
he remaining bones. If, in this position, the ankle be uncovered, it is
o divide one by one all the ligaments without producing any tendency
ement of the bones. One may even separate completely the tibia from
alus left on the table, then replace the tibia in its normal position, and
tical pressure upon it without any tendency for the tibia and astragalus
e displaced. The only movement one can find is a slight gliding down-
d inwards of the head of the astragalus, but the soft parts, which are
e, prevent any displacement of the astragalus.
peration has not yet been performed on the living subject, but we are
ive publicity to the proposal of M. Leon Tripier. The subastragalar
on is one which might with advantage be more practised than it is, as
affording better prospect to a working man than Chopart's operation;
o which the reporter had under his hands, the results were in every
l. But the advantages of M. Leon Tripier's operation appear likely
this a recognized and valuable addition to the surgery of the foot.—
Med. Record, April 15, 1880

Loose Bodies in Joints.

sor H. **Fischer**, of Breslau, has recently published (*Deutsche Zeit-
ür Chirurgie*, Band xii. Heft 4, 5) the results of some inquiries as to the
articular loose bodies (*Gelenkmause*). Although the histology of such

bodies had been thoroughly investigated by Virchow, and many surgical authors had discussed their diagnosis and treatment, very little had been done with respect to their etiology.

The author deals first with loose bodies in healthy joints. These are invariably the result of injury. Cases of this kind are not of frequent occurrence. The joint usually affected is the knee. A loose body may be produced through injury in various ways. A portion of articular cartilage may be torn away, and set free in the joint. Many surgeons hold that loose bodies are very frequently, if not always, produced in this manner. The author records an instance of a loose body appearing in the left knee shortly after an injury to this joint. The body was removed by operation, and found to be composed of articular cartilage. An osseous portion of an epiphysis may likewise be set free through injury, so as to form a loose body. This event is much less frequent than the separation of a portion of articular cartilage. To the ten cases that had been previously recorded, the author adds one from his own practice, in which, after the death of the patient from severe injuries to the head and liver with contusion of the left elbow, a detached piece of the olecranon was found as a loose body in this joint.

Since it cannot be doubted that a loose body may be produced through the breaking away of a cartilaginous or an osseous portion from the articular extremity of a bone, such an event might be fairly assumed in clinical practice when, in the first place, the development of the loose body can be referred to a decided and severe injury followed immediately by considerable disturbance of function, and subsequently by symptoms of loose body in the joint; when, in the second place, it can be made out that before the injury the joint had been sound and capable of performing all its functions; when, finally, the loose body, removed by operation, resembles in its anatomical and histological characters such a piece of cartilage or bone as might have been broken away and set free in the affected joint.

John Hunter held the view that the formation of a floating articular body is usually preceded by hemorrhage into the joint, and that the body itself is a mass of hardened and calcified coagulum. It has been pointed out by Virchow that many articular loose bodies indicate, in their structure, some such mode of formation as this, and are really composed of coagulated portions of extravasated or exuded fluid. According to Professor Fischer, who has observed three instances of this kind, the loose bodies formed from coagulated blood and fibrin are not permanent growths. They seldom become incrusted, and usually, after having existed for some few months, and having caused the common articular disturbances, spontaneously disappear.

That a large foreign body, as, for example, a bullet, may after penetrating a joint, remain there without causing any inflammatory mischief, has been proved by an observation by Volkmann. This, however, is a very rare event, as such a body usually sets up much irritation and reaction, and demands prompt removal. Small foreign bodies may penetrate into the osseous or cartilaginous structures of a joint, and become encapsuled. In a case reported by Mr. Shaw, a portion of a needle formed the nucleus of a floating body of cartilage that was removed from the knee of a young woman. Professor Fischer mentions an instance in which a small portion of a saw used in Ogston's operation was broken off, and remained in the knee-joint without setting up any irritation.

The second group of articular loose bodies comprises all such as are found in the interior of diseased joints, being either products of inflammation or the results of changes in such products. As was first pointed out by Ambroise Paré, these loose bodies may be formed in cases of hydrops articuli through partial coagulation of the accumulated synovial fluid. In an articular affection described by ı under the designation of *hydrops fibrinosus articuli*, the affected joint ɔ be filled with floating bodies of different sizes, many of which are to be pure concretions. This affection has almost invariably been n the knee. One case, however, is recorded by Professor Fischer, in wrist was the affected joint. In an instance of this disease observed lhier, the floating bodies had been regarded as hydatids. Loose arti- es may be formed either through direct osseous transformation of the nembrane, or, without the joint, in the fibrous portion of the capsule. tion of floating bodies through conversion of portions of the synovial into cartilage or bone is of not unfrequent occurrence, especially in ted with chronic *arthritis deformans*. Laennec was the first to point ch bodies may also be developed external to an articulation, and that ally grow inwards and towards the interior of the capsule, becoming in a prolongation of the synovial membrane. Finally, they may be in some movement of the limb, and then become free in the articular he floating bodies thus developed present a characteristic form and They are usually biconvex, one surface being formed of very hard ɔther surface of hyaline cartilage. The affected joint presents very her change, save an increase in the amount of synovia.

ky first showed that loose bodies might be formed in diseased joints ver-growth and pathological metamorphoses of synovial tufts. It is that enlargement of these tufts frequently occurs in association with ry changes in a joint. Cartilage-cells are formed in the swollen and rocesses of synovial membrane, which cells form firstly a chondroma, uently become calcified or form bone. A growth of this kind may, roduced in or external to the synovial membrane, become detached e in the joint. Rokitansky's views as to this mode of origin of loose e been supported by Luschka and Virchow. The loose bodies thus ave each usually the shape of a bean or a kidney, and present three faces and one short concave surface; they are smooth, firm, and vary between the size of a small bean and that of a walnut. Each nposed mainly of hyaline cartilage, with a few dry spots of calcifica- nall deposits of porous bone; the cortical portion presents fibro-carti- ome rare cases there is a small irregularly shaped cavity in the centre e body, which cavity is filled by viscid synovia-like fluid. A loose is kind often presents a persistent stalk, or, more frequently, a trace The body, when dried, shrinks into a small shapeless mass with uneven The development of the loose bodies from tufts of synovial membrane receded by some inflammatory affection of the joint that is associated articular effusion of fluid.

variety of loose articular body is that produced by the breaking away, rity of a joint affected with chronic arthritis deformans, of a piece of d or pathologically developed bone, or of an enchondrosis. This form net with. The loose body thus produced, though usually quite free, bserved during the life of the patient, in consequence of its symptoms ured by those of the chronic inflammatory condition of the joint. Such as have been described had been found during *post-mortem* examina- growth may consist either of true bone covered by a layer, more or of cartilage, or of cartilage studded with osseous deposits. The loose formed has a very irregular form, is usually large, and often presents race of fracture on one of its surfaces or margins. In some very rare the broken off piece of bone or cartilage remains in contact with its nt of attachment, and becomes loosely connected with this by means of a kind of false joint. The author describes two pathological instances of thi condition.

The treatment of loose bodies in joints, Professor Fischer states in concluding h article, has, through the grand and inestimable reformation effected in surge by the antiseptic method, attained a final solution. Whilst formerly the vari methods of operation were anxiously compared and considered, at the present d no surgeon hesitates to prefer over all other proceedings that of incision into t affected joint, and immediate extraction of the loose body, under antiseptic pr cautions. Professor Fischer operates in such cases without the use of the spra but is careful to cleanse with solution of carbolic acid the seat of the operati and all the required instruments, and in most instances treats the joint w Lister's dressings. The joint is not washed out and is not drained; the wou is closed by suture. M. Lucas-Championnière has reported a case in which t joint was washed out with a five per cent. solution of carbolic acid, and th drained. No marked local or general reaction followed this practice. Prof Fischer thinks that injection and drainage are unnecessary in this operation, s the instruments used hardly reach the interior of the joint. No serious loc general symptoms have followed the operation in any of the author's cases; in all, with but one exception, the joint remained movable and capable of perf ing all its functions. In most of the cases, some swelling and tenderness of joint were noted on the third day. These phenomena usually disappear the course of a few days, either spontaneously or after the removal of sutures, and a free discharge of secretion from the wound. The average tion of such treatment is one month. The surgeon, Prof. Fischer rem should always bear in mind the caution given by M. Tillaux against rashly ing an opening into the articulation of the knee; but, with the brilliant re of Lister's method, it is hardly necessary to warn the patient that the remo a loose body from this joint is a very serious operation. Diseased joints to operative interference much better and more readily than joints that are sound.—*London Med. Record*, April 15, 1880.

Midwifery and Gynæcology.

The Administration of Ergot in Labour.

Dr. GLYNN WHITTLE (*Dublin Journ. of Med. Sci.*, Feb. 1880) thinks there is no doubt that ergot judiciously administered will often save a lyi woman from the necessity of a forceps delivery. If there is reason to fear partum hemorrhage, ergot should always be given before the child is born. fifteen- to thirty-minim range of the Pharmacopœial liquid extract is practi useless, but there is a limit to the dose which it is desirable to give. Two drachms may be mentioned as a maximum, but occasionally it is justifiab repeat this quantity. Dr. Whittle also lays down the following rule in rega the administration of ergot. Never administer ergot until the labour is advanced that it could, if necessary, be easily finished with the forceps. cases where tonic uterine contraction follows, threatening the life of the child, not terminating the labour, recourse may then be had to the forceps. If placenta happens to be morbidly adherent, the danger of the complication be greatly augmented by post-partum increased uterine contraction, due to influence of ergot, and of such a case Dr. Whittle quotes an instance w occurred in his own practice.—*Practitioner*, May, 1880.

Alleged Dangers of Intra-uterine Injections of Perchloride of Iron in Cases of Post-partum Hemorrhage.

rederick Pollard, Senior Assistant-Physician to the Liverpool Infir- r Children, has analyzed (*British Med. Journal*, April 24 and May 1, l the British cases of death following one injection of solutions of perchlo- ron into the uterus for primary post-partum hemorrhage which have been l in the last ten or twelve years. He finds that puerperal fever is not one angers to be apprehended from the use of the perchloride. But there are idents which apparently may be caused by the injection. One is the of some of the fluid along the Fallopian tubes to the peritoneal cavity, severe pain and fatal shock, which probably (though not certainly) oc- n one reported case (Dr. Bantock's). The other is the entrance of the fer- solution into the uterine veins, causing phlegmasia dolens, or even giving ardiac or pulmonary embolism and sudden death. This accident may en the cause of death in three of the cases described; but there is no at it can with almost complete certainty be avoided; firstly, by being reful to keep open the cervix with the fingers, so as to allow the free f the fluid injected; secondly, by injecting very slowly and gently, allow- olution to trickle down the sides of the uterus, and by avoiding all un- y force. To attain this end, it is desirable to employ a delivery-tube, nstead of having one large terminal aperture, has a number of small late- , so as to send a coarse spray rather than a full stream against the inte- he uterus; and attention to these precautions will probable reduce the the operation to a minimum.

ven if these dangers were greater than they are, we should not. in his be justified in giving up the operation altogether. It has undoubtedly any lives which were fast ebbing away, when nothing else would stay the flux. If we are to discard every operation which is itself sometimes fatal, uld become of ovariotomy, lithotomy, or amputation of the breast? A looding to death is in far more immediate peril than are those for whom the ns just named are performed. Then why should she be denied a remedy, s saved many women's lives, all other means having failed, because it be absolutely free from danger? Dr. Pollard believes that every prac- ought to carry this, or some equally efficient styptic (if such there be), to se of midwifery to which he is summoned. This conviction has been pon him by the perusal of some of those terrible cases where life has rap- ed away before there was time to fetch any assistance, or any remedies what the attendant had with him.

ollard's experience of the operation, though not extensive, has been alto- avourable. He has used it in cases where injections both of hot water and ar had failed, and where to all appearance the patients would inevitably d without the iron.

ys, "in conclusion, then, I believe that there are some cases of *post-partum* age of so intractable a character that the injection of a solution of the ide of iron into the uterus affords the only chance of saving the patient's d for this reason I consider that, of all the numerous benefits which Dr. has conferred upon obstetric science and practice, not the least important troduction of the method of treatment whose alleged dangers I have in er endeavoured to estimate."

Roseola Uterina.

recent meeting of the Obstetrical Society of Dublin (*British Med. Journal*, , 1880), Dr. **Kidd** read a paper on this disease, which, though by no means unfrequent, had never, as far as he could learn, been described in books. The disease occurred most frequently in patients in childbed, but also followed small operations on the uteri of women who had never been pregnant. He thought it occurred in about three per cent. of all the midwifery cases he had attended. About the third or fourth day after delivery, the patient complained that the skin of the abdomen was irritable and itchy, and, on examining it, an eruption was found very similar to that of scarlatina; next day, the axillæ became affected in a similar way; thence it extended over the chest and neck, but not affecting the face, and down the arms to the hands. The thighs, legs, and back became also covered. During all this time there was no constitutional disturbance, no fever; the pulse and temperature, tonsils and appetite, milk and lochia remained normal. On the second or third day after its first appearance it began to disappear, fading first in the places last affected. Dr. Kidd considered that the erythema was due to nervous derangement, and explained the phenomena on that hypothesis. The nerves supplying the internal surface of the uterus were at pregnancy enlarged; the long-continued irritation of those exposed nerves (after delivery) exhausted the centres with which they were connected, and hence the vaso-motor nerves proceeding from those centres were paralyzed for the time being; the arteries controlled by them relaxed, and allowed an excess of blood to the capillaries of the skin, hence redness and erythema. As soon as the irritation of the peripheral nerves ceased, the centre recovered, and the vaso-motor restraint again contracted the capillaries, and the erythema disappeared without any constitutional disturbance.

Indications for Treatment of Versions and Flexions of the Uterus.

B. S. SCHULTZE remarks (*Archiv für Gynæk.*, Bd. xv. Heft ii. 1879) that the views of authorities upon the mechanical treatment of alterations in the position of the uterus differ as much now as they did thirty or forty years ago. He recapitulates his views as to the importance of the folds of Douglas in conditioning the occurrence of forward or backward displacement. Shortening of these folds from inflammation pulls the cervix backwards and upwards, and so exposes the posterior aspect of the body of the uterus to the intra-abdominal pressure, which, driving the body downwards, produces anteflexion. Conversely, relaxation of the folds of Douglas allows the cervix to sink downwards and forwards, and the intra-abdominal pressure to fall on the anterior surface of the uterine body, and hence retroflexion. If the uterus is more rigid than usual, either through past or present metritis, then anteversion or retroversion is the result respectively, instead of the corresponding flexion. This he holds to be the etiology of the great majority of cases. Occasionally he thinks anteversion or anteflexion arises from peritoneal adhesions between the fundus uteri and the bladder, and retroversion or flexion from parametric fixation of the cervix uteri in front. He does not hold, like many authors, flexion to be a source of more suffering than version. The symptoms especially credited to flexion are dysmenorrhœa and sterility, which are attributed to narrowing of the internal os, and consequent hindrance to the exit of blood and the entry of semen. There is no doubt that the acute flexion of the infantile type often coexists with infantile narrowness of the canal and the orifices; also that with a sharp flexion uterine catarrh, especially in women who have ceased to menstruate, favours the occurrence of stenosis and obliteration of the os internum. But in the majority of cases of flexion of the uterus during sexual life the diagnosis of stenosis only means that there is difficulty in getting a too rigid sound past the point of flexion. Flexion of the uterus does not *per se* produce stenosis. As to sterility, in the majority of women in whom the cause of it is on the male side, the uterus is

ed, because in the majority of healthy women the uterus lies in that
. He does not think flexions without effect in producing sterility, but
rility in cases of flexion is most often due to coexisting complications, and
eldom a mechanical result. In cases of shortening of the folds of Doug-
n the inflammation has entirely passed off, and not the slightest tender-
the part remains, the author has treated the resulting anteflexion by
cal stretching of the folds, by pulling the vaginal portion downwards and
. But this indication can seldom be carried out, because the part in
usually is sensitive, and such traction may then rekindle inflammation.
cases, on the contrary, great relief may be obtained by pushing the
portion yet further backwards, by means of a figure-of-8-shaped pessary.
the anteflexion is increased, but the folds of Douglas are protected from
ension, and thus not only are the pains relieved, but the disappearance
matory processes is favoured. Reposition of the displaced uterus by the
sound he looks upon as useless, for the flexion returns when the replacing
removed. Vaginal pessaries he thinks only give relief by fixing the
d diminishing the tension of Douglas's folds. Intra-uterine stems cer-
aighten the uterus, but the position in which they keep the uterus is as
ved from the normal one as is an anteflexion. That they have been
by good results he attributes to treatment of other kinds simultaneously
ut, and possibly to contraction of the uterus excited by the presence of
body. In cases of displacement the author recommends treatment of
npanying metritis and parametritis. These conditions are often caused
up by accompanying endometritis, and the retention of catarrhal secre-
he uterine cavity. This is best treated by dilatation of the cervix, and
ing out of the uterine cavity with a 2 per cent. solution of carbolic acid.
lt of treatment on these principles is, that the symptoms will disappear,
gh the shape of the uterus be unaltered, menstruation will become pain-
the patient will conceive with an acutely anteflexed uterus. With-
ion and retroflexion it is quite different. Here the displacement is
ot the result but the cause of the morbid phenomena, which must be
y mechanically raising the uterus to its normal position. In the begin-
ay be enough simply to use means which excite uterine contraction. But
placement be pronounced, the uterus must be replaced by bimanual ma-
n, and kept in its proper position by a pessary. If reposition in this
e difficult, he holds it better to anæsthetize the patient, by which we
only replace the uterus, but accurately ascertain the condition of the
gan, than to replace the uterus by means of the sound. The latter pro-
s often possible, but much harm may be done by it. No pessary can
uterus into its normal position. By manual reposition under anæsthe-
y be possible to break down adhesions which retained the uterus in its
position. He has done this without bad results. The pessary required
ich shall draw the cervix backwards, which, being done, the abdominal
will keep the uterus in a state of anteversion. He uses one of the shape
e 8, the cervix being embraced and carried backwards by the posterior
one like a Hodge, the anterior end of which, instead of curving down-
carried so far upwards and backwards, and is so widened, that it presses
cervix. He uses the latter when the vaginal walls have not sufficient
etain the former. The bowels must be kept regular; the vagina must
ntly washed out, and over-filling of the bladder must be avoided. Nu-
ust be improved; the best general tonic, where possible, being sea
While wearing the pessary, pregnancy often takes place, which is a
le occurrence for the patient, for with care during the lying-in the recur-

rence of the displacement may be prevented. The inflammatory complications of the retroverted and retroflexed uterus require no special treatment, the correction of the displacement will cause them to disappear. Backward displacements of the uterus are those in which mechanical treatment is followed by the most strikingly beneficial results. He has used intra-uterine stems in the treatment of retroflexion, but has obtained better results without them. He believes the time is not far off when his hope, expressed seven years ago, that these instruments may come to be seen in historical collections only, will be fulfilled.—*Obstetrical Journal of Great Britain*, April, 1880.

—

Removal of Uterine Fibroids by Laparotomy.

At a late meeting of the Obstetrical Society of London (*Lancet*, May 8, 1880) Mr. **Knowsley Thornton** raised the question of the removal of uterine fibroi by laparotomy. He not only regarded the removal of uterine fibroids by abd minal section as justifiable in certain cases, but believed that the future of the operations would be in no way second to that of ovariotomy. The objections operating by laparotomy for fibroids were—(1) less fatality of fibroids when l alone, as compared with ovarian tumours; (2) the greater frequency of th relief or cure by medical, expectant, or milder surgical treatment; (3) the grea danger of the operations for their removal as compared with ovariotomy. H pointed out how often dangerous operations were undertaken for the relief deformity, and that operations of convenience were now much more safe and j tifiable, thanks to Professor Lister's method. The following proposition w advanced for discussion: Is it justifiable to make an exploratory operation w perfect antiseptic precautions in any case of fibroid tumour of the uterus, wh has resisted medical treatment, and which is either endangering life or prev ing the subject of it from fulfilling the ordinary duties of her sex and positi The great difficulty lies in the present uncertainty of the diagnosis between varieties of uterine fibroids. Complete records of two cases were then given, first a complete hysterectomy, with removal of both ovaries; the second, remo of sessile fibroids and one ovary without opening the uterine cavity. B patients recovered without fever and without any untoward symptom. Th classes of cases were defined, each having a different amount of difficulty risk. The author thought that the term hysterotomy should be given up, that of hysterectomy adopted, but limited to the complete cases, in which whole of the supra-vaginal part of the uterus was removed.

Dr. **Bantock** related two cases in which he had removed fibroid tumours. the first a small tumour weighing two pounds was removed with a part of uterus. The pedicle formed by the uterine body was ligatured and dropp Death occurred from septicæmia, due to slight bleeding from the stump, w the establishment of an open canal through the cervix. In the second, an ternal fibroid weighing twelve pounds was removed, and the pedicle kept exter The patient did well.

Mr. **Doran** said that in the fatal case mentioned by Dr. Bantock he had fo a deep circular ulcer in the cervical canal corresponding to the ligature. He examined also a fatal case under Mr. Thornton's care, in which the pedicle o large fibroid outgrowth had been secured by the clamp. A slough had exten from the stump to the uterus.

Dr. **Playfair** believed that the operation had a great future before it, but experience would not induce him to agree with the statement in Dr. Godse paper, that it was not more dangerous than ovariotomy. Moreover, a pati ian tumour rarely lived if left to herself; a person with fibroid rarely

ATTHEWS DUNCAN thought it demonstrated that the operation had a
gitimate surgery. With increased knowledge of the natural history of
e believed that the use of the operation would be extended beyond what
id men at present imagined. Such tumours were liable to dangerous
nd degenerations, liable to induce peritonitis, liable even to induce can-
ially of the peritoneum. The paramount danger arose from the bleed-
accompanied them and produced a fatal result, he believed, more fre-
an was generally supposed.

ORNTON, in reply, deprecated the fastening of the pedicle up to the
l wall as a dangerous practice. He reminded Dr. Playfair that many
ies were incomparably more difficult than the removal of a pedun-
ubperitoneal fibroid. He had now operated for uterine tumours
nes; in ten cases the operations were completed, in two they were not.
e former died, and one of the latter. In three complete hysterectomies
val of both ovaries, he had one death; one hysterectomy with removal
ary, death from hemorrhage. In three removals of fibrous cystic tu-
recovered.

Medical Jurisprudence and Toxicology.

Case of Poisoning from Carbolic Acid used Surgically.

paper (*Gazetta degli Ospitali*, February, 1880) DE AGOSTINI reviews
a number of cases collected from various sources, demonstrating the
uence which carbolic acid occasionally exercises when applied as a
large open wounds. He records a case which occurred lately in his
nd which illustrates very clearly the bad effects which may follow the
is agent. The patient came under the author's care, suffering from
tis, for which, the presence of pus having been diagnosed, a large
xposing the renal tissues was made in the sacro-lumbar region. A
ube was inserted, and through it the wound was washed out very
h a one per cent. solution of carbolic acid. The incision was further
lint steeped in a two per cent solution of the acid, and the whole cov-
with wadding moistened with a similar solution. Owing to the dis-
ing very copious, the dressings were renewed daily, and the washing
parts very thoroughly performed. In spite, however, of the fact that
ppearances were most satisfactory, the patient's general condition did
ue to improve as it had done for the first ten days after the operation.
attacks of fever occurred daily, with a temperature of 39.2 deg. Cent.
hr.), and were followed on one occasion by a violent attack of dys-
h expectoration of a litre of serous fluid, and great prostration. The
ne occasion was of a dark olive tint. Symptoms of hydrothorax ap-
d a preliminary puncture revealed the existence of fluid, which, how-
ppeared within twenty-four hours. Meanwhile, the general condition
ient becoming steadily worse, and the temperature being always higher
sing of the wound, it was determined to substitute salicylic for carbolic
e effect of the change was remarkable. Within a few hours the tem-
ell to 36.4 deg. (97.5 Fah.) and continued unchanged till convalescence,
ok place rapidly; all symptoms of fever likewise disappearing. The

urine showed only in a very slight degree the suspicious dark colour of carbolic urine, but there was a remarkable deficiency of the sulphates. The author believes that carbolic acid intoxication may cause symptoms of collapse, pulmonary œdema, pleurisy, and pneumonia, with a remittent or intermittent type of fever, proving ultimately fatal. The absence or marked diminution of the sulphates in the urine is the most reliable symptom of carbolic acid poisoning, which, as a rule, will be more likely to occur in those exhausted by chronic affections. The chief danger would seem to be in washing out large cavities such as the bladder or pleura, or large superficial wounds. Though such intoxication is rare, its possibility should always be borne in mind, as also the fact that in any give case there may be an idiosyncrasy rendering the patient intolerant of even th smallest quantity of the acid.—*London Med. Record*, April 15, 1880.

Hygiene.

Diphtheria and Sewer Gas.

The influence of sewer gas in the production of diphtheria has not alw received the attention it deserves; and it seems, therefore, important to chroni well-authenticated cases which seem to have no other cause than the introducti of drain-air into the houses invaded by the disease. Two such cases h recently been recorded as occurring at Newquay, in Cornwall, by Dr. Balla of the Local Government Board, whose caution as an etiologist is well kno It appears that a new tenant commenced one August to occupy a detached almost new house, the water-closet of which was drained into a covered unventilated cesspool in the garden. This house had been previously occu for a short time by a family who had been quite free from illness while resid there. In one of the bed-rooms there was an open rain-water cistern, having overflow or waste pipe which discharged itself into one of the drains connec with the cesspool. The only trap it had was a bell-trap on the top of the pi which, when subsequently examined, was found to be dry. From this p offensive smells had been noticed as proceeding for some time, and from the ro they more or less pervaded the house. In the room where the cistern situated one child slept alone; another child slept with a nurse in a differ room. On January 2d the child who slept in the room containing the cist was attacked with diphtheria and died. No one else in the house suffered. T other fatal case referred to occurred in a good house, which was occupied b family of whom eight children with the mother slept in a large attic roo beneath the floor of which was a rain-water cistern. The waste pipe of t cistern was trapped with a bell-trap, and it terminated in the soil-pipe of water-closet. All the children who slept in this room had attacks of diphthe of varying degrees of severity, and one of them died. On subsequent exami tion of the bell-trap, it was found to be dilapidated, dry, and quite ineffective prevent the rise of foul air from the waste pipe and through the floor into t attic.—*British Med. Journal*, April 24, 1880.

MEDICAL NEWS.

ational Convention of 1880 *for Revising the Pharmacopœia.*

nvention for the sixth decennial revision of the Pharmacopœia of the
ates, in accordance with the call of Dr. James M. Morgan, Assistant
and last surviving officer of the Convention of 1870, met in Washington
sday, May 5th, and was called to order at 12 M. by Dr. Morgan, of
n.

on, Dr. Morgan was elected temporary Chairman, and Dr. D. Webster
f Washington, temporary Secretary.

ir appointed the following Committee on Credentials: Dr. W. S. W.
rger, Mr. A. B. Taylor, and Mr. W. S. Thompson. After a
fifteen minutes, the Committee reported that some of the bodies
sent delegates did not come within the literal interpretation of the
e Convention, and with this explanation it submitted the list of cre-
ceived for the action of the Convention.

n having been made to the admission of the delegations which were
the letter of the call, Dr. Busey, of Washington, in order to perfect
zation of the Convention without delay, moved that the delegates
odies which were specifically included in the call for the Convention,
incorporated State medical societies, incorporated medical colleges,
ed colleges of physicians and surgeons, and incorporated colleges of
'' and concerning whose status there was no question, be admitted.

ey also moved that the delegates from the Medical Departments of
of the Navy, and of the Marine-Hospital Service be admitted.

ey also moved that the delegates from the Medical Society of the
Columbia, which is incorporated, but not technically a "State medical
e admitted. Adopted.

rles Rice, of New York, objected to the admission of the delegation
ennsylvania College of Pharmacy, as it was not incorporated, and he
he had a letter from the Secretary of the Commonwealth of Pennsyl-
at effect. On behalf of the College, it was stated that it was regularly
ed, and its delegation offered an opportunity to inspect its charter,
eal of the State attached, to any member of the Convention who
satisfy himself upon this point. The objection then fell.

n was also made to the admission of the delegation from the Phila-
ounty Medical Society. Dr. Robert E. Rogers, of Philadelphia,
at the delegates from the Philadelphia County Medical Society be
to the Convention. This motion gave rise to considerable discus-
enuous objection to their admission was made on the ground that
y did not come within the letter of the call for the Convention; and
ed that, had it been known that these delegates would be admitted,
York County Medical Society, as well as other county medical socie-
d have sent delegations to the Convention. On behalf of the Phila-
ounty Medical Society, it was stated that it was an incorporated
ciety; that more than a year ago it had written to Dr. Morgan, the only

surviving officer of the previous convention, asking if it were entitled to
presentation in this convention, to which Dr. Morgan replied that at the Co
vention of 1870 delegates had been admitted from similar bodies which d
not come within the literal reading of the call, and that, from precedent,
believed that the Society's delegates were entitled to admission; that thereup
the Society had appointed a Committee on Revision of the Pharmacopœia, wh
had prepared a lengthy and carefully considered report which the Societ
delegates were instructed to present to the Convention. Dr. Rogers's mot
was carried, and, a division having been called, the vote was declared to
thirty-five in the affirmative and twenty-two in the negative.

On motion, a Committee on Nomination of Permanent Officers was appoint
consisting of one member from each body entitled to representation in the C
vention, each delegation to name its own member of the Committee, and
Convention then took a recess until 3 P. M.

Upon the reassembling of the Convention, Dr. J. F. Judge, of Cincinnati,
behalf of the Committee on Nominations, presented the following report:
President, Robert Amory, M.D., of Brookline, Mass.; for Vice-Presidents,
S. C. Busey, of Washington, and Mr. P. W. Bedford, of New York; for Se
tary, Dr. F. A. Castle, of New York; for Assistant Secretary, Dr. C. H.
Kleinschmidt, of Washington, D. C. On motion of Dr. Rogers, of Philadelp
the report was accepted and adopted.

Dr. Amory then assumed the chair, and thanked the Convention for the ho
it had conferred upon him.

On motion of Prof. Maisch, of Philadelphia, Dr. E. R. Squibb, of New Y
was elected a member of the Convention.

Reports on the Revision of the Pharmacopœia were received from the A
can Pharmaceutical Association, Massachusetts Medical Society, Colle
Physicians of Philadelphia, Philadelphia College of Pharmacy, Philade
County Medical Society, Pennsylvania Pharmaceutical Association, Mar
College of Pharmacy, National Medical College of Washington, National Co
of Pharmacy of Washington, and the Louisville College of Pharmacy. Refe
to the Committee on Revision to be hereafter appointed.

On motion of Prof. Maisch, it was resolved,

That the Committee on Nominations be instructed to nominate a commi
of revision and publication, consisting of twenty-five members; and to rep
plan for revising and publishing the Pharmacopœia, and to make provision for
revision of the United States Pharmacopœia in the future.

May 6th. The Convention met at 10 P. M. to receive the report of the C
mittee on Nominations. The plan for the revision of the Pharmacopœia
sented by the Committee was adopted with slight amendment, and is practic
the plan proposed by the Committee of the American Pharmaceutical Asso
tion. It was decided not to admit therapeutical considerations, statements
doses, or tables, or antidotes to poisons; that the formulæ should be in parts
weight, and should be constructed, when practicable, so that the end quan
of all finished products should be one hundred parts; and that the single alp
betical arrangement be adopted.

The following Committee on Revision and Publication was elected: D
Robert Amory, of Brookline, Mass.; F. A. Castle, of New York; D.
Huntington, U. S. A.; B. F. Gibbs, U. S. N.; Laurence Johnson, of N
York; J. F. Judge, of Cincinnati; H. G. Piffard, of New York; W. S.
Ruschenberger, of Philadelphia; E. R. Squibb, of New York; E. S. Wood,
Boston; T. F. Wood, of Wilmington, N. C.; T. G. Wormley, of Philadelphi
and Messrs. Oscar Oldberg, U. S. Marine-Hospital Service; P. W. Bedfo

York; C. Lewis Diehl, of Louisville; Louis Dohme, of Baltimore;
oliber, of Boston; John M. Maisch, of Philadelphia; G. F. H. Mar-
ston; H. B. Parsons, of Washington; J. P. Remington, of Philadel-
rles Rice, of New York; A. B. Taylor, of Philadelphia; W. S.
, of Washington; O. A. Wall, of St. Louis.

mmitte on Revision and Publication was instructed to award the pub-
the Pharmacopœia to the publishing house offering the best terms, the
to hold the copyright, the price of the work to be limited, and the
sold through the ordinary trade channels. The authority was also
iblish a supplement to the Pharmacopœia at the end of five years, or
necessary. The Committee was authorized to fill all vacancies which
in its body, and to drop, by a vote of two-thirds of the Committee,
er who may neglect to perform the work which he had accepted, or
to attend five consecutive meetings of the Committee without valid
The Committee was also empowered to employ expert labour.

rdered that the call for the next convention should include all incorpo-
ical and pharmaceutical societies, incorporated medical and pharma-
lleges, and the medical departments of the army, navy, and marine-
rvice of the United States.

of the Convention was then called, and seventy-four delegates re-

s, of Philadelphia, stated that the "College of Physicians and Sur-
e City of New York," whose name appeared on the roll, was believed
iety which had long since ceased to exist, and, therefore, not entitled
tation in the Convention, and he inquired of its delegation if it was
rated society which was now in actual existence; a reply was given
mative, and the further consideration of the subject was laid upon the

s also called attention to the fact that it was desirable and just that
ork Academy of Medicine should be represented in the Convention, and
it had a delegation present, it had not yet been formally admitted,
ny special motion or—as it was, like the Philadelphia County Medical
either a State medical society nor a college of physicians—by the general
offered by Dr. Busey on the first day. Dr. Busey then moved, and
seconded it, that the delegation from the New York Academy of Medi-
mitted to the Convention, which was unanimously adopted.

al complimentary resolutions were then adopted, and the Convention,
M. on May 7th, adjourned *sine die*.

angements of the local Committee of Reception added much to the
f the visiting delegates. Receptions were held on the evening of the

---

College of Physicians and Surgeons in the City of New York" (which should
founded with the well-known College of Physicians and Surgeons (Medical
olumbia Coll.), New York) does not appear in the New York Medico-Histori-
y's Register, nor has it for many years past been represented in the New
Society. Since the adjournment of the Convention it transpires that it is
ork County Medical Society under another name. (See Proceedings of the
nty Medical Society in *Medical Record*, May 15, p. 551.) It is not apparent
New York County Medical Society did not openly send its delegates under its
nt name, with its honourable record, but, at an ordinary stated meeting,
ve assumed for ten minutes another name, and thus, by a questionable pro-
sguised itself beyond recognition; nor why the statement, without qualifica-
made in argument in the previous day's debate in opposition to the admis-
e delegation from another county medical society, that the New York County
ociety did not and would not send delegates to the Convention.

5th at the Corcoran Art Gallery; on the afternoon of the 6th at the W House by the President; in the evening at the Naval Observatory by Ad and Mrs. Rogers; and on the morning of the 7th an excursion to Mount V non, with a handsome collation on the boat, was tendered to the delegates their ladies by the physicians of Washington.

Typhoid Fever and Polluted Water.—Upwards of four hundred of the inh tants of Perth have been suffering from attacks of low fever and diarrhœa, m festly arising from the pollution of the water-supply. It appears that, while water-pipes were under repair, a plug came out, and for a short time the wat the river Tay, contaminated with sewage and other city refuse, was allowe flow into the town pipes. Although the influx lasted only a few minutes, i calculated that as much as fifty thousand gallons of the public supply were pregnated with noxious particles.—*British Med. Journal*, May 1, 1880.

Use of Arsenic in Manufactured Articles for Domestic Use.—The Co of the Society of Arts, in consequence of the numerous cases of reputed po ing by arsenical wall-papers and other articles in general use, have appoint committee to inquire into the practicability of preventing the employme arsenic in any processes by which it is allowed to remain in finished goods, to obtain evidence as to the effect a total prohibition of the use of such proc or the prohibition of the sale of articles produced thereby, would have upon ous trades. This is a practical step towards the solution of a question inv large trade interests.—*British Med. Journal*, May 1, 1880.

The Cartwright Endowment.—The late Benjamin Cartwright, Esq., of ark, N. J., has bequeathed to the Alumni Association of the College of P cians and Surgeons (Medical Department of Columbia College), New Yor thousand dollars, with one-half of which to found a "Cartwright prize," the best essay, containing original work, on some subject connected wit art of medicine or surgery, to be open only to the competition of the Alum the College. With the remaining five thousand dollars there is to be establ a course of "Cartwright Lectures," to be under the control of the Alumni sociation.

Dr. Roberts Bartholow, of Philadelphia, has accepted the invitation of Councillors of the Alumni Association to deliver the first course of "Cartw lectures" during the session of 1880–81.

Meetings of Medical Societies.—The thirty-first annual meeting of the Am can Medical Association will be held at New York on Tuesday, June 1st, u the presidency of Dr. Lewis A. Sayre. The arrangements for the meeting in charge of an efficient committee, of which Dr. T. Gaillard Thomas is Chairm

The American Neurological Society will meet in the same city on the 15t June.

The following State societies will hold their meetings this month:—

West Virginia Medical Society, at Parkersburg, June 2.
Massachusetts Medical Society, at Boston, June 9.
Minnesota Medical Society, at Albert Lea, June 15.
New Hampshire Medical Society, at Concord, June 15.
Ohio Medical Society, at Cleveland, June 15.

Medical and Chirurgical Faculty of Maryland.—The eighty-second ann meeting of this body was held at Baltimore, April 13, 14, 15, 1880; Dr. S.

Baltimore, President, in the chair. The annual oration was delivered ohn W. Mallet, of the University of Virginia. His subject was "The Science for its own Sake upon the Medical Profession."

owing officers were elected for the ensuing year: President, H. P. C. .D. Vice-Presidents, Drs. L. McLane Tiffany and G. Ellis Porter. Secretary, Dr. Wilson G. Register.

a State Medical Association held its third annual meeting in New March 31st and April 1st and 2d; Dr. J. W. Dupree, President, in The following office-bearers were elected for the ensuing year: Presi- . Smith, M.D., of St. Mary. Vice-Presidents, Drs. D. R. Fox, J. on, P. S. Postell, A. A. Lyon, G. M. Brumby, O. P. Langworthy. Dr. L. F. Salomon. The next meeting will be held at New Orleans, Wednesday in March, 1881.

Society of the State of Tennessee.—The 47th annual session of this s convened at Knoxville on the 6th of April; Dr. E. M. Wight, of a, President, in the chair. The following officers were elected for year: President, B. B. Lenoir, M.D., of Lenoir's. Vice-Presi- M. M. Alexander, of Knoxville, W. M. Clarke, of Nashville, and T. The next meeting will be held at Nashville, on the first Tuesday in .

Society of the State of California.—The tenth annual session of this convened at San Francisco on the 21st of April; Dr. A. W. Saxe, lara County, President, in the chair. The following officers were the ensuing year: President, Dr. F. W. Todd, of Stockton. Vice- Drs. G. G. Tyrrell, of Sacramento; G. W. Davis, of Chico; A. H. Oakland; and C. A. Kirkpatrick, of San Mateo. Secretary, Wallace of Sacramento. The next meeting will be held at San Francisco, on 'ednesday in April, 1881.

er of Health.—It affords us sincere pleasure to record the fact that in on of the new British Ministry the President of the Local Govern- d, upon whom it devolves to carry out the provisions of the Public ts, has been assigned a seat in the Cabinet, thus making the health the country an integral part of the ministerial policy, and insuring t has long been promised in a figure of speech, a policy having for *Sanitas sanitatum, omnia est sanitas.*

ophone.—At the meeting of the Académie de Médecine of March 30, .EBERT presented a new instrument, made under his directions by ieu Fils, for the diagnosis of vesical calculi. The instrument is com- small cylindro-conical drum of glazed pasteboard to the extremity of xploring sound is attached. Such is the resonant power of this appa- he smallest stroke, an insensible grazing of the beak of the sound upon ne bladder, becomes greatly amplified, and resounds in the drum where to be produced. The illusion is said to be complete, the bladder, be brought under the ear of the surgeon. It is needless to dwell on of the lithophone for finding vesical calculi and small fragments after The instrument is figured in *Le Progrès Médical*, 3 Avril, 1880.

Pharmacopœia.—A commission for the revision of the German Phar- will meet next autumn, and it is expected that the new edition will be 881.

A Hint to Schoolmasters.—It is a notorious fact that scarlet fever and ot infectious diseases are constantly introduced into schools by pupils in wh homes are cases sick or convalescing from these diséases. With a view to venting occurrences of this character, we note with pleasure that the prin of an English school has recently issued a circular to parents, with a view to vent the attendance of those pupils who have been exposed in their famili any of the infectious diseases, and we commend his example to all in sim authority.

Personal.—Princess Pauline, of Wurtemburg, has been recently marri Dr. Willim, of Breslau. It will be remembered that a princess of Hols Sonderburg, sister to Prince Christian, of Schleswig-Holstein, is the wi Professor Esmarch, of Kiel.

Literary Notes.

The last number of the *Bibliothek for Læger*, a prominent Danish medical nal, published at Copenhagen, has for its leading paper a careful and co translation of Dr. S. W. Gross's elaborate and critical study of sarcoma of the bones which originally appeared in the numbers of the *American Journal of Medical Sciences* for July and October, 1879.

A work on the "Diagnosis of Diseases of the Spinal Cord," by Dr. Go is announced by Churchill, of London.

Dr. J. Wickham Legg, of St. Bartholomew's Hospital, has just publi through Mr. H. K. Lewis, of London, a volume "On the Bile, Jaundic Bilious Diseases." Mr. Lewis has in press a treatise on "Dwelling-H their Sanitary Construction and Arrangements," by Dr. Corfield, Profes Hygiene in University College, London.

We have received the first number of the "Archives of Laryngolo quarterly journal, edited by Dr. Louis Elsberg, in conjunction with Drs. J. Cohen, Frederick I. Knight, and George M. Lefferts. It contains original cles, clinical notes, transactions of Laryngological Societies, Reviews, abstra laryngological literature, and notes and queries. The scope of the "Arch embraces Human and Comparative Morphology and Physiology of the Th and Pathology and Therapeutics of Throat Diseases, in the widest signific of these terms, and the contents of its first number are of a high stand merit, and the typographical appearance all that could be desired. It is lished by G. P. Putnam's Sons, and deserves the support of all interested i specialty.

OBITUARY RECORD.—At London, on the 11th of April, aged 78, WIL SHARPEY, M.D., LL.D., F.R.S.

Mr. Sharpey was born at Arbroath, in Scotland, on April 1, 1802. He st at the University of Edinburgh, and in 1821 obtained the diploma of the College of Surgeons of Edinburgh. The following winter he studied Cli Medicine and Surgery in Paris, and in 1823 received the degree of M.D. the University of Edinburgh. After practising for a while at Arbroath he ceeded to the continent and devoted himself to the study of anatomy and ph ology. In 1831 he began his career as a teacher of anatomy as an extra-m lecturer at Edinburgh, and five years later he was elected to the chair of anat and physiology in the University of London, as the successor of Dr. Jones Qu which position he held until 1874. For years he held the enviable and unq tionable position of being the greatest teacher of anatomy and physiology in Gr Britain. He was a contributor to the "Cyclopædia of Anatomy and Phy ology," and one of the editors of Sharpey and Quain's Anatomy.

their high professional standing.

I.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENC

EDITED BY I. MINIS HAYS, M.D.,

for more than half a century has maintained its position in the front rank medical literature of the world. Cordially supported by the profession of Ame circulates wherever the language is read, and is universally regarded as a natio ponent of American medicine—a position to which it is entitled by the disting names from every section of the Union which are to be found among its collabo It is issued quarterly, in January, April, July, and October, each number co about three hundred octavo pages, appropriately illustrated wherever necess large portion of this space is devoted to Original Communications, embracing from the most eminent members of the profession throughout the country.

Following this is the REVIEW DEPARTMENT, containing extended reviews b petent writers of prominent new works and topics of the day, together with n elaborate Analytical and Bibliographical Notices, giving a fairly complete s medical literature.

Then follows the QUARTERLY SUMMARY OF IMPROVEMENTS AND DISCO IN THE MEDICAL SCIENCES, classified and arranged under different heads, a ishing a digest of medical progress, abroad and at home.

Thus during the year 1879 the "JOURNAL" contained 67 Original Commu mostly elaborate in character, 147 Reviews and Bibliographical Notices, and 215 in the Quarterly Summaries, illustrated with 70 wood engravings.

That the efforts thus made to maintain the high reputation of the "JOUR successful, is shown by the position accorded to it in both America and E leading organ of medical progress:—

This is universally acknowledged as the leading American Journal, and has been conducted by Dr. Hays alone until 1869, when his son was associated with him. We quite agree with the critic, that this journal is second to none in the language, and cheerfully accord to it the first place, for nowhere shall we find more able and more impartial criticism, and nowhere such a repertory of able original articles. Indeed, now that the "British and Foreign Medico-Chirurgical Review" has terminated its career, the American Journal stands without a rival.—*London Med. Times and Gazette*, Nov. 24, 1877.

The best medical journal on the continent.—*Boston Med. and Surg. Journal*, April, 1879.

The present number of the American Journal is an exceedingly good one, and gives every promise of maintaining the well-earned reputation of the review. Our venerable contemporary has our best wishes, and we can only express the hope that it may continue its work with as much vigor and excellence for the next fifty years as it has exhibited in the past.—*London Lancet*, Nov. 24, 1877.

The Philadelphia Medical and Physi issued its first number in 1820, and, aft career, was succeeded in 1827 by th Journal of the Medical Sciences, a world-wide reputation; the ablest and oldest periodicals in the world—a journal an unsullied record.—*Gross's History of Med. Literature*, 1876.

The best medical journal ever publish or America.—*Va. Med. Monthly*, May, 1

It is universally acknowledged to be American medical journal, and, in our second to none in the language.—*Boston Surg. Journal*, Oct. 1877.

This is the medical journal of our count the American physician abroad will poi greatest satisfaction, as reflecting the st cal culture in his country. For a great it has been the medium through which writers have made known their disco observations.—*Address of L. P. Yand fore International Med. Congress*, Sept.

And that it was specifically included in the award of a medal of merit to lishers in the Vienna Exhibition in 1873.

The subscription price of the "AMERICAN JOURNAL OF THE MEDICAL SC has never been raised during its long career. It is still FIVE DOLLARS per and when paid for in advance, the subscriber receives in addition the "M NEWS AND ABSTRACT," making in all nearly 2000 large octavo pages per an of postage.

II.

THE MEDICAL NEWS AND ABSTRACT.

Thirty-seven years ago the "MEDICAL NEWS" was commenced as a m convey to the subscribers of the "AMERICAN JOURNAL" the clinical instruct

* Communications are invited from gentlemen in all parts of the country. Elaborate articles by the Editor are paid for by the publishers.

urrent information which could not be accommodated in the Quarterly. It consisted
f sixteen pages of such matter, together with sixteen more known as the Library
epartment and devoted to the publishing of books. With the increased progress of
ence, however, this was found insufficient, and some years since another periodical,
own as the "Monthly Abstract," was started, and was furnished at a moderate
e to subscribers to the "American Journal." These two monthlies will here-
r be consolidated, under the title of "The Medical News and Abstract,"
will be furnished *free of charge* in connection with the "American Journal."
he "News and Abstract" will consist of 64 pages monthly, in a neat cover. It
contain a Clinical Department in which will be continued the series of Origi-
American Clinical Lectures, by gentlemen of the highest reputation
ghout the United States, together with a choice selection of foreign Lectures and
ital Notes and Gleanings. Then will follow the Monthly Abstract, systemati-
arranged and classified, and presenting five or six hundred articles yearly; and
number will conclude with a News Department, giving current professional
igence, domestic and foreign, the whole fully indexed at the close of each volume,
ring it of permanent value for reference.

stated above, the subscription price to the "News and Abstract" will be
Dollars and a Half per annum, invariably in advance, at which rate it will rank
e of the cheapest medical periodicals in the country. But it will also be fur-
d, free of all charge, in commutation with the "American Journal of the
cal Sciences," to all who remit Five Dollars in advance, thus giving to the
iber, for that very moderate sum, a complete record of medical progress through-
e world, in the compass of about two thousand large octavo pages.

his effort to furnish so large an amount of practical information at a price so un-
entedly low, and thus place it within the reach of every member of the profes-
the publishers confidently anticipate the friendly aid of all who feel an interest in
semination of sound medical literature. They trust, especially, that the sub-
to the "American Medical Journal," will call the attention of their
tances to the advantages thus offered, and that they will be sustained in the
vor to permanently establish medical periodical literature on a footing of cheap-
ever heretofore attempted.

MIUM FOR OBTAINING NEW SUBSCRIBERS TO THE "JOURNAL."

y gentleman who will remit the amount for two subscriptions for 1880, one of
at least must be for a *new subscriber*, will receive as a premium, free by mail,
y of any one of the following recent works:—

"Barnes's Manual of Midwifery" (see p. 24),
"Tilbury Fox's Epitome of Diseases of the Skin," new edition (see p. 18),
"Fothergill's Antagonism of Medicines" (see p. 16),
"Holden's Landmarks, Medical and Surgical" (see p. 6),
"Browne on the Use of the Ophthalmoscope" (see p. 29),
"Flint's Essays on Conservative Medicine" (see p. 15),
"Sturges's Clinical Medicine" (see p. 14),
"Swayne's Obstetric Aphorisms," new edition (see p. 21),
"Tanner's Clinical Manual" (see p. 5),
"West on Nervous Disorders of Children" (see p. 20).

* Gentlemen desiring to avail themselves of the advantages thus offered will do
to forward their subscriptions at an early day, in order to insure the receipt of
lete sets for the year 1880.

The safest mode of remittance is by bank check or postal money order, drawn
e order of the undersigned. Where these are not accessible, remittances for the
urnal" may be made at the risk of the publishers, by forwarding in registered
s. Address,

Henry C. Lea's Son & Co., Nos. 706 and 708 Sansom St., Phila., Pa.

DUNGLISON (ROBLEY), M.D.,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: C taining a concise explanation of the various Subjects and Terms of Anatomy, Phy Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Jurisprudence, and Dentistry. Notices of Climate and of Mineral Waters; Form Officinal, Empirical, and Dietetic Preparations; with the Accentuation and Etymol the Terms, and the French and other Synonymes; so as to constitute a French as English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly ified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and some royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, half Russia, $8. (*Just Issued.*)

The object of the author from the outset has not been to make the work a mere lexi dictionary of terms, but to afford, under each, a condensed view of its various medical rel and thus to render the work an epitome of the existing condition of medical science. St with this view, the immense demand which has existed for the work has enabled him, in rep revisions, to augment its completeness and usefulness, until at length it has attained the p of a recognized and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain th viable reputation. During the ten years which have elapsed since the last revision, the ad to the nomenclature of the medical sciences have been greater than perhaps in any similar of the past, and up to the time of his death the author labored assiduously to incorporate thing requiring the attention of the student or practitioner. Since then, the editor h equally industrious, so that the additions to the vocabulary are more numerous than in an vious revision. Especial attention has been bestowed on the accentuation, which will be marked on every word. The typographical arrangement has been much improved, ren reference much more easy, and every care has been taken with the mechanical executio work has been printed on new type, small but exceedingly clear, with an enlarged page, the additions have been incorporated with an increase of but little over a hundred pag the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan. 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by th "that the work, which possesses for him a fili as an individual interest, will be found wort tinuance of the position so long accorded t standard authority."—*Cincinnati Clinic*, Ja

It has the rare merit that it certainly ha in the English language for accuracy and references.—*London Medical Gazette*

As a standard work of reference, as one of if not the very best, medical dictionary in lish language, Dunglison's work has been w for about forty years, and needs no words on our part to recommend it to the memb medical, and, likewise, of the pharmaceu fession. The latter especially are in need work, which gives ready and reliable inf on thousands of subjects and terms which liable to encounter in pursuing their daily tions, but with which they cannot be expe familiar. The work before us fully supp want.—*Am. Journ. of Pharm.*, Feb. 1874.

A valuable dictionary of the terms emp medicine and the allied sciences, and of t tions of the subjects treated under each hea flects great credit on its able American aut well deserves the authority and popularity obtained.—*British Med. Journ.*, Oct. 31, 18

Few works of this class exhibit a grade ment of patient research and of scientific le extent of the sale of this lexicon is sufficie tify to its usefulness, and to the great serv ferred by Dr. Robley Dunglison on the pro and indeed on others, by its issue.—*London* May 13, 1875.

HOBLYN (RICHARD D.), M.D.

A DICTIONARY OF THE TERMS USED IN MEDICINE THE COLLATERAL SCIENCES. Revised, with numerous additions, by ISAAC M.D., Editor of the "American Journal of the Medical Sciences." In one large 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00.

It is the best book of definitions we have, and ought always to be upon the student's table.—*S Med. and Surg. Journal.*

RODWELL (G. F.), F.R.A.S., &c.

A DICTIONARY OF SCIENCE: Comprising Astronomy, Ch istry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Mag Mechanics, Meteorology, Pneumatics, Sound, and Statics. Preceded by an Essay History of the Physical Sciences. In one handsome octavo volume of 694 pages, many illustrations: cloth, $5.

A *CENTURY OF AMERICAN MEDICINE*, 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas, and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25. (*Lately Issued.*)

This work appeared in the pages of the American Journal of the Medical Sciences during the r 1876. As a detailed account of the development of medical science in America, by gentle- of the highest authority in their respective departments, the profession will no doubt wel e it in a form adapted for preservation and reference.

EILL (*JOHN*), *M.D.*, *and* *SMITH* (*FRANCIS G.*), *M.D.*,
Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

ARTSHORNE (*HENRY*), *M. D.*,
Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery, and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00. (*Lately Issued.*)

can say with the strictest truth that it is the work of the kind with which we are acquainted. bodies in a condensed form all recent contribu- to practical medicine, and is therefore useful ry busy practitioner throughout our country, s being admirably adapted to the use of stu- of medicine. The book is faithfully and ably ted.—*Charleston Med. Journ.*, April, 1875.

work is intended as an aid to the medical nt, and as such appears to admirably fulfil its by its excellent arrangement, the full compi- f facts, the perspicuity and terseness of lan- , and the clear and instructive illustrations e parts of the work.—*American Journ. of acy*, Philadelphia, July, 1874.

volume will be found useful, not only to stu- , but to many others who may desire to refresh memories with the smallest possible expendi- f time.—*N. Y. Med. Journal*, Sept. 1874.

student will find this the most convenient and l book of the kind on which he can lay his .—*Pacific Med and Surg. Journ.*, Aug. 1874.

is is the best book of its kind that we have ever ined. It is an honest, accurate, and concise pend of medical sciences, as fairly as possible esenting their present condition. The changes the additions have been so judicious and tho- h as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr. Hartshorne.—*Detroit Rev. of Med. and Pharm.*, Aug. 1874.

The work before us, however, has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the latest advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept. 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874

UDLOW (*J. L.*), *M.D.*

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy, and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations. In one handsome royal 12mo. volume of 816 large pages, cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suit- e for the office examination of students, and for those preparing for graduation.

ANNER (*THOMAS HAWKES*), *M.D.*, *&c.*

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS. Third American from the Second London Edition. Revised and Enlarged by Tilbury Fox, M. D., Physician to the Skin Department in University College Hospital, &c. In one neat volume small 12mo., of about 375 pages, cloth, $1 50.

⁎ On page 3, it will be seen that this work is offered as a premium for procuring new bscribers to the "American Journal of the Medical Sciences."

GRAY (HENRY), F.R.S.,

Lecturer on Anatomy at St. George's Hospital, London.

ANATOMY, DESCRIPTIVE AND SURGICAL. The Drawings H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the Autho Dr. CARTER. With an Introduction on General Anatomy and Development by HOLMES, M.A., Surgeon to St. George's Hospital. A new American, from the ei enlarged and improved London edition. To which is added "LANDMARKS, MEDICAL SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Ma of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, half Russia, $7 50. (*Just Ready.*)

The author has endeavored in this work to cover a more extended range of subjects than tomary in the ordinary text-books, by giving not only the details necessary for the student also the application of those details in the practice of medicine and surgery, thus rendering it a guide for the learner, and an admirable work of reference for the active practitioner. Th gravings form a special feature in the work, many of them being the size of nature, near original, and having the names of the various parts printed on the body of the cut, in pla figures of reference, with descriptions at the foot. They thus form a complete and splendid s which will greatly assist the student in obtaining a clear idea of Anatomy, and will also se refresh the memory of those who may find in the exigencies of practice the necessity of rec the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, a thorough treatise on systematic, descriptive, and applied Anatomy, the work will be fo essential use to all physicians who receive students in their offices, relieving both precepto pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions a hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has se requisite to maintain its reputation as a complete and authoritative standard text-book and of reference. Still further to increase its usefulness, there has been appended to it the r work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Sur —which gives in a clear, condensed, and systematic way, all the information by which the titioner can determine from the external surface of the body the position of internal parts. complete, the work, it is believed, will furnish all the assistance that can be rendered by ty illustration in anatomical study. No pains have been spared in the typographical execu the volume, which will be found in all respects superior to former issues. Notwithstandi increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as her at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr. Holden, which was noticed by us on p. 53 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable edition of Mr. Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug. 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical,*" which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The w simply indispensable, especially this present ican edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. as an appendix, renders this the most practi complete treatise available to American st who find in it a comprehensive chapter on anatomy, about all that can be taught on and special anatomy, while its treatment region, from a surgical point of view, in the able section by Mr. Holden, is all that will be tial to them in practice.—*Ohio Medical Re* Aug. 1878.

It is difficult to speak in moderate terms new edition of "Gray." It seems to be as perfect as it is possible to make a book deve any branch of medical science. The labors eminent men who have successively revise eight editions through which it has passed, seem to leave nothing for future editors to do. addition of Holden's "Landmarks" will mak indispensable to the practitioner of medici surgery as it has been heretofore to the stude regards completeness, ease of reference, ut beauty, and cheapness, it has no rival. No dent should enter a medical school without it physician can afford to have it absent fro library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,

Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL. From the 2d Lon Ed. In one handsome volume, royal 12mo., of 128 pages: cloth, 88 cents. (*Now Re*

HEATH (CHRISTOPHER), F.R.C.S.,

Teacher of Operative Surgery in University College, London.

PRACTICAL ANATOMY: A Manual of Dissections. From Second revised and improved London edition. Edited, with additions, by W. W. K M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philade In one handsome royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3 leather, $4 00.

LLEN (HARRISON), M.D.
Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY: INCLUDING ITS MEDICAL and Surgical Relations. For the Use of Practitioners and Students of Medicine. With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M. D., Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. (*In Press.*)

n this elaborate work, which has been in active preparation for several years, the author has ht to give, not only the details of descriptive anatomy in a clear and condensed form, but also practical applications of the science to medicine and surgery. The work thus has claims upon attention of the general practitioner, as well as of the student, enabling him not only to re- h his recollections of the dissecting room, but also to recognize the significance of all varia- s from normal conditions. The marked utility of the object thus sought by the author is evident, and his long experience and assiduous devotion to its thorough development are a ient guarantee of the manner in which his aims have been carried out. No pains have been d with the illustrations. Those of normal anatomy are from original dissections, drawn on e by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, the manner of "Holden" and "Gray," and in every typographical detail it will be the t of the publisher to render the volume worthy of the very distinguished position which is ipated for it.

LLIS (GEORGE VINER).
Emeritus Professor of Anatomy in University College, London.

EMONSTRATIONS OF ANATOMY; Being a Guide to the Know-ledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25. (*Just Ready.*)

work has long been known in England as the leading authority on practical anatomy, favorite guide in the dissecting-room, as is attested by the numerous editions through it has passed. In the last revision, which has just appeared in London, the accomplished has sought to bring it on a level with the most recent advances of science by making the ry changes in his account of the microscopic structure of the different organs, as devel- y the latest researches in textural anatomy.

Demonstrations is the favorite text-book English student of anatomy. In passing eight editions it has been so revised and to the needs of the student that it would t it had almost reached perfection in this line. The descriptions are clear, and the s of pursuing anatomical investigations are ith such detail that the book is honestly to its name.—*St. Louis Clinical Record*, 879.

ccess of this old manual seems to be as well d in the present as in the past volumes. ok seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

ILSON (ERASMUS), F.R.S.

A SYSTEM OF HUMAN ANATOMY, General and Special. Edited by W. H. GOBRECHT, M.D., Professor of General and Surgical Anatomy in the Medical College of Ohio. CARPENTER (WILLIAM B.), M.D., F.R.S., F.G.S., F.L.S.,

Registrar to University of London, etc.

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, University of Oxford. A new American from the Eighth Revised and Enlarged English Edition, with Notes and Additions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the University of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pages, with two plates and 373 engravings on wood; cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Issued.*)

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears. The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago, looks now as if it had been a received and established fact for years. In this encyclopædic way it is unrivalled. Here, as it seems to us, is the great value of the book; one is safe in sending a student to it for information on almost any given subject, perfectly certain of the fulness of information it will convey, and well satisfied of the accuracy with which it will there be found stated.—*London Med. Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work. In fact the entire work has been brought up to date, and bears evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med. Journal*, Jan. 1877.

FOSTER (MICHAEL), M.D., F.R.S.,

Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. A new American, from the third English edition. Edited with notes and additions by EDWARD T. REICHERT, M.D., Demonstrator of Experimental Therapeutics in Univ. of Penna. In one handsome royal 12mo. volume of 1030 pages, with 259 illustrations. Cloth, $1 50. Leather, $2 00. (*Just Ready.*)

AMERICAN EDITOR'S PREFACE.

The high reputation acquired on both sides of the Atlantic by Dr. Foster's "Text-Book on Physiology," as a lucid exposition of functional physiology, in its most modern aspect, has seemed to call for an edition more thoroughly adapted to the wants of the American student. The plan of the author has presupposed an acquaintance with the details of physiological anatomy such as the student is accustomed to look to in his treatises on physiology. The absence of these details has rendered many parts of the work vague, if not altogether incomprehensible, and has therefore proved a serious drawback to the usefulness of the book as an accompaniment to lectures on physiology, as it is usually taught in our schools, and this deficiency the editor has endeavored to supply, by brief notes and the introduction of a large number of illustrations.

The almost limitless amount of material accumulated by modern research has rendered difficult the task of selection and compression, without exceeding the reasonable limits of a convenient text-book. In his selection the editor has been guided by his experience in the wants of students, and has endeavored merely to present, in the most concise form, such facts as would seem to be indispensable to a correct appreciation of the structure and function of the important organs. In accomplishing this, his additions have considerably exceeded his expectations, amounting to about 140 pages, including the illustrations which have been increased in number from 72 to 259. If he shall thus have succeeded in rendering this admirable work better fitted for the wants of the American student, he will feel abundantly rewarded.

Nothing has been omitted from the English edition, and all additions have been distinguished by insertions in brackets [—].

The great popularity of "Foster's Text-book of Physiology," both in England and in this country, renders it unnecessary to say anything further regarding its merit. We shall, therefore, simply point out that, in the American edition, numerous important additions have been made to the text of the third English edition whereby the usefulness of the work as a text-book for students has been greatly increased.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

Foster's Physiology is a most excellent book, not only for the student, but especially for the physician who wishes to revise and increase his physiological knowledge. The style of the author is clear, his arrangement and classification of subjects very satisfactory, and he has presented in this volume a most valuable exposition of physiology as now known.—*The Am. Practitioner*, April, 1880.

Every sentence shows careful and mature thought, and the student, at the outset, will have to make up his mind that Foster's work requires *study*, and not simply a cursory reading. The work is well illustrated, and its method clear and logical, and eminently practical, and fully up to the present advanced status of this most important branch of medicine. Foster's work is a credit to his scholarship and research, and will be accepted everywhere by the student and practitioner as reliable authority. It should be in the hands of every medical student.—*St. Louis Clin. Record*, April, 1880.

In the presentation of the latest and the most serviceable facts the work is peculiarly rich, and the author is also decidedly happy in his freedom from tedium or useless details, and omission of so very little that a book for students needs to teach. The style is scholarly, and the volume a thoroughly welcome one.—*Cincinnati Med. Gaz. and Recorder*, April, 1880.

THE SAME. English Student's Edition, without notes or additions. In one small 12mo. volume of 804 pages with 72 illustrations. Cloth, 75 cents.

ALTON (*J. C.*), *M.D.*,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Sixth edition, thoroughly revised and enlarged, with three hundred and sixteen illustrations on wood. In one very beautiful octavo volume, of over 800 pages. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Issued.*)

uring the past few years several new works on phy-gy, and new editions of old works, have appeared, peting for the favor of the medical student, but will rival this new edition of Dalton. As now en-d, it will be found also to be, in general, a satisfac- work of reference for the practitioner.—*Chicago Journ. and Examiner*, Jan. 1876.

f. Dalton has discussed conflicting theories and usions regarding physiological questions with a e, a fulness, and a conciseness which lend fresh- and vigor to the entire book. But his discussions been so guarded by a refusal of admission to those ative and theoretical explanations, which at best in the minds of observers themselves as only pro-ities, that none of his readers need be led into errors while making them a study.—*The Medical* d, Feb. 19, 1876.

revision of this great work has brought it forward he physiological advances of the day, and renders t has ever been, the finest work for students ex-—*Nashville Journ. of Med. and Surg.*, Jan. 1876.

clearness and perspicuity, Dalton's Physiology ended itself to the student years ago, and was a t relief from the verbose productions which it ted. Physiology has, however, made many ad- since then—and while the style has been pre- intact, the work in the present edition has been t up fully abreast of the times. The new chemical and nomenclature have also been introduced present edition. Notwithstanding the multi- f text-books on physiology, this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent. of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realized. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ*, Dec. 1875.

We heartily welcome this, the sixth edition of this admirable text book, than which there are none of equal brevity more valuable. It is cordially recommended by the Professor of Physiology in the University of Louisiana, as by all competent teachers in the United States, and wherever the English language is read, this book has been appreciated. The present edition, with its 316 admirably executed illustrations, has been carefully revised and very much enlarged, although its bulk does not seem perceptibly increased.—*New Orleans Medical and Surgical Journal*, March, 1876.

The present edition is very much superior to every other, not only in that it brings the subject up to the times, but that it does so more fully and satisfactorily than any previous edition. Take it altogether it remains in our humble opinion, the best text book on physiology in any land or language.—*The Clinic*, Nov. 6, 1875.

EENE (*WILLIAM H.*), *M.D.*,

Demonstrator of Chemistry in Med. Dept, Univ. of Penna.

MANUAL OF MEDICAL CHEMISTRY. For the Use of Students. Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages. With illustrations. Cloth, $1 75. (*Just Issued.*)

well written, and gives the latest views on hemistry, a subject with which most phys- re not sufficiently familiar. To those who sh to improve their knowledge in that direc e can heartily recommend this work as being y of a careful perusal.—*Phila. Med. and Surg.* ter, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit The descriptions, though brief, are clear, and in most cases sufficient for the purpose This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

ASSEN (*ALEXANDER*),

Professor in the Royal Polytechnic School, Aix la-Chapelle.

LEMENTARY QUANTITATIVE ANALYSIS. Translated with notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Just Ready.*)

probably the best manual of an elementary extant, insomuch as its methods are the best. hes by examples, commencing with single inations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

LER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY. Translated with additions from the Eighth German Edition. By IRA REMSEN, M D, Ph.D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 550 pp, cloth, $3.

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M.D. With illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1200 pages, with 200 illustrations; cloth, $6.

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical. Revised and corrected by Henry Watts, B.A., F.R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illustrations. A new American, from the twelfth and enlarged London edition. Edited by Robert Bridges, M.D. In one large royal 12mo. volume, of over 1000 pages; cloth, $2 75; leather, $3 25. (*Just Issued.*)

Two careful revisions by Mr. Watts, since the appearance of the last American edition of "Fownes," have so enlarged the work that in England it has been divided into two volumes. In reprinting it, by the use of a small and exceedingly clear type, cast for the purpose, it has been found possible to comprise the whole, without omission, in one volume, not unhandy for study and reference. The enlargement of the work has induced the American Editor to confine his additions to the narrowest compass, and he has accordingly inserted only such discoveries as have been announced since the very recent appearance of the work in England, and has added the standards in popular use to the Decimal and Centigrade systems employed in the original.

Among the additions to this edition will be found a very handsome colored plate, representing a number of spectra in the spectroscope. Every care has been taken in the typographical execution to render the volume worthy in every respect of its high reputation and extended use, and though it has been enlarged by more than one hundred and fifty pages, its very moderate price will still maintain it as one of the cheapest volumes accessible to the chemical student.

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more than a thousand pages, but with less than this no fair representation of chemistry as it now is can be given. The type is small but very clear, and the sections are very lucidly arranged to facilitate study and reference.—*Med. and Surg. Reporter*, Aug. 3, 1878.

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former *prestige*.—*Boston Jour. of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make any remarks relating to the general character of Fownes' Manual. For over twenty years it has held *the* foremost place as a text-book, and the elaborate and thorough revisions which have been made from time to time leave little chance for any wide awake rival to step before it.—*Canadian Pharm. Jour.*, Aug. 1878.

As a manual of chemistry it is without a superior in the language.—*Md. Med. Jour.*, Aug. 1878.

ATTFIELD (JOHN), Ph.D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL, AND PHARMACEUTICAL; including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, $2 50; leather, $3 00. (*Just Ready.*)

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it, little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition. The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*Am. Jour. of Pharmacy*, May, 1879.

A standard work like Attfield's Chemistry need only be mentioned by its name, without further comments. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. The author has bestowed arduous labor on the revision, and the extent of the information thus introduced may be estimated from the fact that the index contains three hundred new references relating to additional material.—*Druggists' Circular and Chemical Gazette*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges in the United States. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Cincinnati Medical News*, April, 1879.

The popularity which this work has enjoyed is owing to the original and clear disposition of the facts of the science, the accuracy of the details, and the omission of much which freights many treatises heavily without bringing corresponding instruction to the reader. Dr. Attfield writes for students, and primarily for medical students; he always has an eye to the pharmacopœia and its officinal preparations; and he is continually putting the matter in the text so that it responds to the questions with which each section is provided. Thus the student learns easily, and can always refresh and test his knowledge.—*Med and Surg. Reporter*, April 19, '79.

We noticed only about two years and a half ago the publication of the preceding edition, and remarked upon the exceptionally valuable character of the work. The work now includes the whole of the chemistry of the pharmacopœia of the United States, Great Britain, and India.—*New Remedies*, May, 1879.

BLOXAM (*C. L.*),

Professor of Chemistry in King's College, London.

CHEMISTRY, INORGANIC AND ORGANIC. From the Second London Edition. In one very handsome octavo volume, of 700 pages, with about 300 illustrations. Cloth, $4 00; leather, $5 00. (*Lately Issued.*)

e have in this work a complete and most excel- t text-book for the use of schools, and can heart- recommend it as such.—*Boston Med. and Surg.* rn., May 28, 1874.

he above is the title of a work which we can most icatiously recommend to students of chemis- It is as easy as a work on chemistry could be , at the same time that it presents a full account t science as it now stands. We have spoken e work as admirably adapted to the wants of nts; it is quite as well suited to the require- s of practitioners who wish to review their istry, or have occasion to refresh their memo- n any point relating to it. In a word, it is a to be read by all who wish to know what is emistry of the present day.—*American Prac- er*, Nov. 1873.

It would be difficult for a practical chemist and teacher to find any material fault with this most admirable treatise. The author has given us almost a cyclopædia within the limits of a convenient volume, and has done so without penning the *useless* paragraphs too commonly making up a great part of the bulk of many cumbrous works. The progressive scientist is not disappointed when he looks for the record of new and valuable processes and discoveries, while the cautious conservative does not find its pages monopolized by uncertain theories and speculations. A peculiar point of excellence is the crystallized form of expression in which great truths are expressed in very short paragraphs. One is surprised at the brief space allotted to an important topic, and yet, after reading it, he feels that little, if any more should have been said. Altogether, it is seldom you see a text-book so nearly faultless.—*Cincinnati Lancet* Nov. 1873.

LOWES (*FRANK*), *D.Sc., London.*

Senior Science-Master at the High School, Newcastle-under Lyme, etc.

N ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS. Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. From the Second and Revised English Edition, with about fifty illustrations on wood. In one very handsome royal 12mo. volume of 372 pages: cloth, $2 50. (*Just Issued.*)

hort, concise, and eminently practical. We e heartily commend it to students, and espe- those who are obliged to dispense with a Of course, a teacher is in every way desi- t a good degree of technical skill and prac- owledge can be attained with no other r than the very valuable handbook now nsideration.—*St. Louis Clin. Record*, Oct.

rk is so written and arranged that it can be ended by the student without a teacher, and iptions and directions for the various work are so simple, and yet concise, as to be interesting and intelligible. The work is unincumbered with theoretical deductions, dealing wholly with the practical matter, which it is the aim of this comprehensive text-book to impart. The accuracy of the analytical methods are vouched for from the fact that they have all been worked through by the author and the members of his class, from the printed text. We can heartily recommend the work to the student of chemistry as being a reliable and comprehensive one.—*Druggists' Advertiser*, Oct. 15, 1877.

'S TECHNOLOGY; or Chemistry Applied to rts, and to Manufactures. With American ions by Prof. WALTER R. JOHNSON. In two very handsome octavo volumes, with 500 wood engravings, cloth, $6 00.

RRISH (*EDWARD*),

Late Professor of Materia Medica in the Philadelphia College of Pharmacy.

TREATISE ON PHARMACY. Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Fourth Edition, thoroughly revised, by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations; cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

r. Parrish's great work on pharmacy it only s to be said that the editor has accomplished k so well as to maintain, in this fourth edi- e high standard of excellence which it had d in previous editions, under the editorship of mplished author. This has not been accom- without much labor, and many additions and ements, involving changes in the arrange- the several parts of the work, and the addi- much new matter. With the modifications ected it constitutes, as now presented, a com- n of the science and art indispensable to the cist, and of the utmost value to every oner of medicine desirous of familiarizing with the pharmaceutical preparation of the which he prescribes for his patients.—*Chi- Med. Journ.*, July, 1874.

work is eminently practical, and has the rare of being readable and interesting, while it pre- strictly scientific character. The whole work the greatest credit on author, editor and pub It will convey some idea of the liberality which n bestowed upon its production when we men- at there are no less than 280 carefully executed trations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honored place on our own bookshelves.—*Dublin Med. Press and Circular*, Aug. 12, 1874.

We expressed our opinion of a former edition in terms of unqualified praise, and we are in no mood to detract from that opinion in reference to the present edition, the preparation of which has fallen into competent hands. It is a book with which no pharmacist can dispense, and from which no physician can fail to derive much information of value to him in practice.—*Pacific Med. and Surg. Journ.*, June, '74.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiegand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

FARQUHARSON (ROBERT), M.D.,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA. S

cond American edition, revised by the Author. Enlarged and adapted to the U. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of pages: cloth, $2.25. (*Just Ready.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ. of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodyi latest revision of the Pharmacopœia, together w the antidotes to the more prominent poisons, such of the newer remedial agents as seemed ne sary to the completeness of the work. Tab weights and measures, and a good alphabetic dex end the volume.—*Druggists' Circular Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity which a second edition is demanded may be as an indication that the sense of appreciation value of reliable information regarding the remedies is not entirely overwhelmed in the tion of pathological studies, characteristic of t sent day. This work certainly merits the su has so quickly achieved.—*New Remedies*, Jul

---

STILLÉ (ALFRED), M.D.,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Tr

on the Action and Uses of Medicinal Agents, including their Description and Hi Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of abo pages. Cloth, $10; leather, $12; half Russia, $13. (*Lately Issued.*)

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct. 1875.

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents, Dr. Stillé's is "*par excellence*" the work. The work being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely reissuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg. Journal*, Dec. 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia o peutics.—*Chicago Medical Journal*, Feb. 1

The rapid exhaustion of three editions and versal favor with which the work has been by the medical profession, are sufficient pr excellence as a repertory of practical and formation for the physician. The edition fully sustains this verdict, as the work has b fully revised and in some portions rewritt ing it up to the present time by the ad chloral and croton-chloral, nitrite of amyl ride of methylene, methylic ether, lithi pounds, gelseminum, and other remedi *Journ. of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival multitude of its citations and the fulness of search into clinical histories, and we must a place in the physician's library; not, i fully representing the present state of know pharmacodynamics, but as by far the most co treatise upon the clinical and practical side question.—*Boston Med. and. Surg. Journal*, 1874.

GRIFFITH (ROBERT E.), M.D.

A UNIVERSAL FORMULARY, Containing the Methods of Pr

ing and Administering Officinal and other Medicines. The whole adapted to Physici Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by J MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In o and handsome octavo volume of about 800 pp., cl., $4 50; leather, $5 50. (*Lately I*

To the druggist a good formulary is simply indispensable, and perhaps no formulary has been more extensively used than the well-known work before us. Many physicians have to officiate, also, as druggists. This is true especially of the country physician, and a work which shall teach him the means by which to administer or combine his remedies in the most efficacious and pleasant manner, will always hold its place upon his shelf. A formulary of this kind is of benefit also to the city physician in largest practice.—*Cincinnati Clinic*, Feb. 21, 1874.

A more complete formulary than it is in ent form the pharmacist or physician could desire. To the first some such work is ind ble, and it is hardly less essential to the prac who compounds his own medicines. Much is contained in the introduction ought to b mitted to memory by every student of me As a help to physicians it will be found inva and doubtless will make its way into librar already supplied with a standard work of th —*The American Practitioner*, Louisville, J

Prof of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa.

Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex.

Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready.*)

PREFACE TO THE SECOND EDITION.

e demand which has exhausted in a few months an unusually large edition of the National ensatory is doubly gratifying to the authors, as showing that they were correct in thinking the want of such a work was felt by the medical and pharmaceutical professions, and that efforts to supply that want have been acceptable. This appreciation of their labors has ulated them in the revision to render the volume more worthy of the very marked favor which it has been received. The first edition of a work of such magnitude must necessarily ore or less imperfect; and though but little that is new and important has been brought ht in the short interval since its publication, yet the length of time during which it was ng through the press rendered the earlier portions more in arrears than the latter. The rtunity for a revision has enabled the authors to scrutinize the work as a whole, and to duce alterations and additions wherever there has seemed to be occasion for improve- or greater completeness. The principal changes to be noted are the introduction of seve- ugs under separate headings, and of a large number of drugs, chemicals, and pharma- al preparations classified as allied drugs and preparations under the heading of more ant or better known articles: these additions comprise in part nearly the entire German acopœia and numerous articles from the French Codex. All new investigations which to the authors' notice up to the time of publication have received due consideration.

series of illustrations has undergone a corresponding thorough revision. A number have dded, and still more have been substituted for such as were deemed less satisfactory.

new matter embraced in the text is equal to nearly one hundred pages of the first edition. erable as are these changes as a whole, they have been accommodated by an enlargement page without increasing unduly the size of the volume.

numerous additions have been made to the sections which relate to the physiological of medicines and their use in the treatment of disease, great care has been taken to them as concise as was possible without rendering them incomplete or obscure. The ave been expressed in the terms both of troy weight and of the metrical system, for the of making those who employ the Dispensatory familiar with the latter, and paving the its introduction into general use.

Therapeutical Index has been extended by about 2250 new references, making the total r in the present edition about 6000.

articles there enumerated as remedies for particular diseases are not only those which, authors' opinion, are curative, or even beneficial, but those also which have at any time employed on the ground of popular belief or professional authority. It is often of as consequence to be acquainted with the worthlessness of certain medicines or with the limits of their power, as to know the well attested virtues of others and the conditions which they are displayed. An additional value possessed by such an Index is, that it ins the elements of a natural classification of medicines, founded upon an analysis of the s of experience, which is the only safe guide in the treatment of disease.

evidence of success, seldom paralleled, clearly how well the authors have met the g needs of the pharmaceutical and medical ions. Gratifying as it must be to them, they mbraced the opportunity offered for a thor- evision of the whole work, striving to em- within it all that might have been omitted in mer edition, and all that has newly appeared cient importance during the time of its col- tion, and the short interval elapsed since the us publication. After having gone carefully h the volume we must admit that the authors abored faithfully, and with success, in main- g the high character of their work as a com- m meeting the requirements of the day, to one can safely turn in quest of the latest in- ion concerning everything worthy of notice in tion with Pharmacy, Materia Medica, and peutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

with great pleasure that we announce to our the appearance of a *second* edition of the al Dispensatory. The total exhaustion of the dition in the short space of six months, is a at testimony to the value placed upon the by the profession. It appears that the rapid the first edition must have induced both the s and the publisher to make preparations for edition immediately after the first had been d, for we find a large amount of new matter d and a good deal of the previous text altered improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

CORNIL (V.), ***AND*** ***RANVIER (L.).***
Prof. in the Faculty of Med., Paris. *Prof. in the College of France.*

MANUAL OF PATHOLOGICAL HISTOLOGY.

Translated, wi Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Sur to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in U of Penna., and by HENRY C. SIMES. M D., Demonstrator of Pathological Histology the Univ. of Pa. In one very handsome octavo volume of over 700 pages. with 350 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

The work of Cornil and Ranvier is so well known as a lucid and accurate text-book o important subject, that no apology is needed in presenting a translation of it to the Amer profession. It is only necessary to say that the labors of Drs. Shakespeare and Simes h been by no means confined to the task of rendering the work into English. As it appear France, in successive portions, between 1868 and 1876, a part of it, at least, was somewh arrears of the present state of science, while the diffuseness of other portions rendered co sation desirable. The translators have, therefore, sought to bring the work up to the and, at the same time, to reduce it in size, as far as practicable, without impairing its pleteness These changes will be found throughout the volume, the most extensive bei the sections devoted to Sarcoma, Carcinoma, Tuberculosis, the Bloodvessels, the Mamma, the classification of tumors. Corresponding modifications have been made in the very ex sive and beautiful series of illustrations, and every care has been taken in the typograp execution to render it one of the most attractive volumes which have issued from the Amer press.

The translators have done their work very well indeed, rendering it into smooth and excellent English, and in their selection of new material they have in the main used good discrimination. We heartily commend the book as one of the best works on the subject.—*Boston Med. and Surg. Journal*, March 11, 1880.

Their book is not a collection of the work of others, but has been written in the laboratory beside the microscope. It bears the marks of personal knowledge and investigation upon every page, controlled by and controlling the work of others. . . . In short, its translation has made it the best work in pathology attainable in our language, one that every student, certainly, ought to have.—*Archives of Medicine*, April, 1880.

This work, in the original, has for years past occupied a prominent place in the library of French pathologists, as we should naturally be led to believe from the reputation of the distinguished authors Now that it has been presented to the English student for the first time, it will be perused with unusual interest. The illustrations are means the least valuable part of the work. I pensable as they are to any work of this na in the work before us the artist has succee producing cuts which will prove unusually val to the reader. The translation is well done, gives evidence throughout the volume that i made by a person thoroughly conversant wi subject.—*N. Y. Med. Gazette*, Feb. 28, 1880.

This will be found an exceedingly inte and valuable work by all who are engaged i study of or take an interest in, histology— or morbid. The material which was utilized preparation was derived from autopsies and tions in the hospitals of Paris, which are rich in it. Nothing was taken for grant everything verified by microscopical inve by the authors themselves in their own labo assisted by their pupils. As an aid to micro in their investigations it will be found inval in fact, the very best with which we are acqu —*Cincinnati Med. News*, February, 1880.

FENWICK (SAMUEL), M.D.,
Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS.

From Third Revised and Enlarged English Edition. With eighty-four illustrations on In one very handsome volume, royal 12mo., cloth, $2 25. (*Just Issued.*)

GREEN (T. HENRY), M.D.,
Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School.

PATHOLOGY AND MORBID ANATOMY.

Third American, fr the Fourth and Enlarged and Revised English Edition. In one very handsome volume of 332 pages, with 132 illustrations; cloth, $2 25. (*Now Ready.*)

This is unquestionably one of the best manuals on the subject of pathology and morbid anatomy that can be placed in the student's hands, and we are glad to see it kept up to the times by new editions. Each edition is carefully revised by the author, with the view of making it include the most recent advances in pathology, and of omitting whatever may have become obsolete.—*N. Y. Med. Jour.*, Feb. 1879.

The treatise of Dr. Green is compact, clearly expressed, up to the times, and popular as a text-book, both in England and America. The cuts are sufficiently numerous, and usually well made. I present edition, such new matter has been add was necessary to embrace the later results in p logical research. No doubt it will continue to the favor it has received at the hands of the p sion.—*Med and Surg. Reporter*, Feb. 1, 1879.

For practical, ordinary daily use, this is und edly the best treatise that is offered to stude pathology and morbid anatomy.—*Cincinnati cet and Clinic*, Feb. 8, 1879.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY Translated, with Notes and Additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00.

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE;

designed for the use of Students and Practitioners of Medicine. Fourth edition, revised and enlarged. In one large and closely printed octavo volume of about 1100 pp.; cloth, $6 00; or strongly bound in leather, with raised bands, $7 00. (*Lately Issued.*)

is excellent treatise on medicine has acquired elf in the United States a reputation similar to enjoyed in England by the admirable lectures r Thomas Watson. We have referred to many most important chapters, and find the revi- poken of in the preface is a genuine one, and e author has very fairly brought up his matter level of the knowledge of the present day. The has this great recommendation, that it is in one e, and therefore will not be so terrifying to the nt as the bulky volumes which several of our h text-books of medicine have developed into. —*ish and Foreign Med.-Chir. Rev.*, Jan. 1875.

of course unnecessary to introduce or eulogize ew standard treatise. The present edition en enlarged and revised to bring it up to the r's present level of experience and reading. His own clinical studies and the latest contributions to medical literature both in this country and in Europe, have received careful attention, so that some portions have been entirely rewritten, and about seventy pages of new matter have been added.—*Chicago Med Jour.*, June, 1873.

Has never been surpassed as a text-book for students and a book of ready reference for practitioners. The force of its logic, its simple and practical teachings, have left it without a rival in the field. *N. Y.—Med. Record*, Sept. 15, 1874.

It is given to very few men to tread in the steps of Austin Flint, whose single volume on medicine, though here and there defective, is a masterpiece of lucid condensation and of general grasp of an enormously wide subject.—*Lond. Practitioner*, Dec. '73.

THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases.

Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

here that the skill and learning of the great n are displayed He has given us a store- of medical knowledge, excellent for the stu- venient for the practitioner, the result of a of the most faithful clinical work, collect- energy as vigilant and systematic as un- nd weighed by a judgment no less clear observation is close.—*Archives of Medi-* . 1879.

hor of the above work has anticipated a g felt by those for whom it was especially —the clinical student during his pupilage, busy practitioner. He has given to the profession a very necessary and useful mplete in detail, accurate in observation, statement.—*St. Louis Courier of Med.*, 79.

is every reason to believe that this book e well received. The active practitioner is tly in need of some work that will enable obtain information in the diagnosis and nt of cases with comparatively little labor. hat has the faculty of expressing himself clearly, and at the same time so concisely as to enable the searcher to traverse the entire ground of his search, and at the same time obtain all that is essential, without plodding through an interminable space.—*N. Y. Med. Jour.*, Nov. 1879

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*S. Louis Clin. Record*, Oct. 1879.

It is venturing little to say that there are few men so well fitted as Dr. Flint to impart information on these last mentioned subjects, and the present work is a timely one as relates both to the author's capacity to undertake it and the need for it as an accompaniment to the multitude now issued, in which the subject of treatment is but little considered.—*New Remedies*, Nov. 1879.

THE SAME AUTHOR.

ESSAYS ON CONSERVATIVE MEDICINE AND KINDRED TOPICS.

In one very handsome royal 12mo. volume. Cloth, $1 38. (*Just Issued.*)

ATSON (THOMAS), M.D., &c.

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,

Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE. Se

American edition, revised by the Author. Edited, with Additions, by JAMES H. H INSON, M.D., Physician to the Penna. Hospital. In one handsome octavo vol nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half B $6 50. (*Now Ready.*)

In reprinting this work from the recent thoroughly revised second English editi author has made such corrections as seemed advisable, and has added a chapter on I The Editor has likewise revised his additions in the light of the latest experience, work is presented as reflecting in every way the most modern aspect of medical scie as fully entitled to maintain the distinguished position accorded to it on both sides Atlantic as an authoritative guide for the student, and a complete though concise reference for the practitioner. Notwithstanding the author's earnest effort at comp the additions have amounted to about one-tenth of the previous edition: but by the enlarged page these have been accommodated without increasing the size of the volume a reduction in the price renders it one of the cheapest works accessible to the profession.

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science. The chapter on diseases of the skin and of the nervous system, with a new one on insanity compiled from the best sources outside of the author's own long experience, and the valuable portion relating to general pathology, aid greatly in completing an exceptionally good book for purposes of reference and instruction.—*Boston Medical and Surgical Journal*, February, 1880.

The popularity of the work depends, a upon the clear and incisive way in whi written, and the attention to details likely in practice, rather than the discussion of q of theory.—*New Remedies*, Jan 1880.

What we said of the first edition, we c increased emphasis, repeat concerning this: page is characterized by the utterances of a ful man. What has been said, has been w and the book is a fair reflex of all that is *known* on the subjects considered."—*O Recorder*, Jan. 7, 1880.

This is not only one of the latest and m prehensive works out on the general Theory and Practice of Medicine, but it is tionably one of the best.—*So Med. Pra* Jan. 1880.

HABERSHON (S. O.), M.D.

Senior Physician to and late Lecturer on the Principles and Practice of Medicine a Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING T

of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, tines, and Peritoneum. Second American, from the third enlarged and revise lish edition. With illustrations. In one handsome octavo volume of over 500 Cloth, $3 50. (*Now Ready.*)

This valuable treatise on diseases of the stomach and abdomen has been out of print for several years, and is therefore not so well known to the profession as it deserves to be. It will be found a cyclopædia of information, systematically arranged, on all diseases of the alimentary tract, from the mouth to the rectum. A fair proportion of each chapter is devoted to symptoms, pathology, and therapeutics. The present edition is fuller than former ones in many particulars, and has been thoroughly revised and amended by the author. Several new chapt been added, bringing the work fully up to th and making it a volume of interest to the pra in every field of medicine and surgery. P nutrition is in some form associated with all we have to combat, and we need all the li can be obtained on a subject so broad and Dr Habershon's work is one that every pra should read and study for himself.—*N. Y Journ.*, April, 1879.

REYNOLDS (J. RUSSELL), M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE. WITH NOTES AND ADDITIONS BY HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. Sold only by subscription. Price per vol., in cloth, $5.00; in sheep. $6.00: half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

UME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.
ME II. (*just ready*) contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.
ME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR
SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE
CUTANEOUS SYSTEM.

ynolds's SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance
first volume, the well-deserved reputation of being the work in which modern British
ine is presented in its fullest and most practical form. This could scarce be otherwise in
of the fact that it is the result of the collaboration of the leading minds of the profession,
subject being treated by some gentleman who is regarded as its highest authority—as for
nce, Diseases of the Bladder by Sir HENRY THOMPSON, Malpositions of the Uterus by
Y HEWITT, Insanity by HENRY MAUDSLEY, Consumption by J. HUGHES BENNET, Dis-
f the Spine by CHARLES BLAND RADCLIFFE, Pericarditis by FRANCIS SIBSON, Alcoholism
NCIS E. ANSTIE, Renal Affections by WILLIAM ROBERTS, Asthma by HYDE SALTER,
al Affections by H CHARLTON BASTIAN, Gout and Rheumatism by ALFRED BARING GAR-
Constitutional Syphilis by JONATHAN HUTCHINSON, Diseases of the Stomach by WILSON
Diseases of the Skin by BALMANNO SQUIRE, Affections of the Larynx by MORELL MAC-
, Diseases of the Rectum by BLIZARD CURLING, Diabetes by LAUDER BRUNTON, Intes-
iseases by JOHN SYER BRISTOWE, Catalepsy and Somnambulism by THOMAS KING CHAM-
Apoplexy by J. HUGHLINGS JACKSON, Angina Pectoris by Professor GAIRDNER, Emphy-
the Lungs by Sir WILLIAM JENNER, etc. etc. All the leading schools in Great Britain
ntributed their best men in generous rivalry, to build up this monument of medical sci-
St. Bartholomew's, Guy's, St Thomas's, University College, St Mary's in London, while
burgh, Glasgow, and Manchester schools are equally well represented, the Army Medical
at Netley, the military and naval services, and the public health boards. That a work
ed in such a spirit, and carried out under such auspices should prove an indispensable
y of facts and experience, suited to the daily wants of the practitioner, was inevitable, and
ess which it has enjoyed in England, and the reputation which it has acquired on this
he Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.
ge size and high price having kept it beyond the reach of many practitioners in this
who desire to possess it, a demand has arisen for an edition at a price which shall ren-
cessible to all. To meet this demand the present edition has been undertaken. The
mes and five thousand pages of the original have, by the use of a smaller type and double
, been compressed into three volumes of over three thousand pages, clearly and hand-
printed, and offered at a price which renders it one of the cheapest works ever presented
American profession.

not only is the American edition more convenient and lower priced than the English;
o better and more complete. Some years having elapsed since the appearance of a
of the work, additions are required to bring up the subjects to the existing condition
ce. Some diseases, also, which are comparatively unimportant in England, require more
e treatment to adapt the articles devoted to them to the wants of the American physi-
and there are points on which the received practice in this country differs from that
abroad. The supplying of these deficiencies has been undertaken by HENRY HARTS-
M.D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored
er the work fully up to the day, and as useful to the American physician as it has proved
his English brethren. The number of illustrations has also been largely increased, and
t spared to render the typographical execution unexceptionable in every respect.

y too much praise can scarcely be given to
e book. It is a cyclopædia of medicine
by some of the best men of Europe. It is
eful information such as one finds frequent
in one's daily work; for no one head can
carry all the knowledge one needs in gen-
ctice, and one must refer sometimes to one's

Louisville Med. News, Jan. 31, 1880.

ynolds' System of Medicine" is justly con-
the most popular work on the principles and
of medicine in the English language. The
utors to this work are gentlemen of well-
reputation on both sides of the Atlantic.
ntleman has striven to make his part of the
practical as possible, and the information
ed is such as is needed by the busy practi-
—*St. Louis Med. and Surg. Journ.*, Jan. 20,

Hartshorne has made ample additions and
, all of which give increased value to the
, and render it more useful to the Ameri-
ctitioner. There is no volume in English
literature more valuable, and every pur-
r will, on becoming familiar with it, congrat-
himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar.—*Gaillard's Med. Journ.*, Feb. 1880.

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Dia Prognosis, Morbid Anatomy, and Treatment. A Manual for Students and Pract In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*New*

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope, there is no book which for clearness of expression, and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has a plain, practical book, by aid of which, chooses may train his eye to the recog light but significant differences. The de are neither too vague nor over-refined; t tions for treatment are clear and succinct.— *Brain*, April, 1880.

The author has handled his subject in a concise manner, and as a text-book to st manual will be found useful.—*Medical a cal Reporter*, March 27, 1880.

The author's task has been well done and duced one of the best recent works upon th subject of which it treats; there is no work which gives a better view of the element and principles of dermatology.—*New Orlea cal and Surgical Journal*, April, 1880.

This excellent little book is the first w distinguished pupil of Jonathan Hutchins commends itself above all by its clearness, and precision.—*Paris Annales de Derma de Syphiligraphie*, 23 April, 1880.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,

Professor of Venereal Diseases at the Col. of Phys. and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL

EASES. Including the results of recent investigations upon the subject. Fourth revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half $6 25. (*Just Ready.*)

This work, on its first appearance, immediately took the position of a standard auth its subject wherever the language is spoken, and the success of an Italian translatio that it is regarded with equal favor on the Continent of Europe. In repeated editions the labored sedulously to render it more worthy of its reputation, and in the present revi pains have been spared to perfect it as far as possible. Several years having elaps the publication of the third edition, much material has been accumulated during the by the industry of syphilologists, and new views have been enunciated. All this confirmed by observation and experience, has been incorporated; many portions of the been rewritten, the series of illustrations has been enlarged and improved, and the wh be regarded rather as a new work than as a new edition. It is confidently presented as a level with the most advanced condition of syphilology, and as a work to which the tioner may refer with the certainty of finding clearly and succinctly set forth whatev within the scope of such a treatise.

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and, we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.— *of Medicine*, April, 1880.

This now classical work on venereal dis to us in its fourth edition rewritten, e materially improved in every way. Dr. we had every reason to expect, has perf part of his work with unusual excellence that what has been written has done but tice to the merits of this truly great tre *Louis Courier of Medicine*, Feb. 1880

We find that we have here practically —that the statement of the title-page, as that it has been largely rewritten, is a modest announcement for the important the text. After a thorough examination sent edition, we can assert confidently th mous labor we have described has been faithfully and conscientiously perform *Journ. Med. Sci.*, Jan. 1880.

It is one of the best general treatises diseases with which we are acquainted, cially to be recommended as a guide to the of syphilis.—*London Practitioner*, March

COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN.

Fourth Edition, revised and enlarged. In one handsome octavo volume of about 750 pages, with illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

ery marked favor with which this work has been received wherever the English lan- is spoken, has stimulated the author, in the preparation of the Fourth Edition, to spare s in the endeavor to render it worthy in every respect of a continuance of professional ce. Many portions of the volume have been rewritten, and much new matter intro- but by an earnest effort at condensation, the size of the work has not been materially d.

period which has elapsed since the third f the work, so extensive have been the ad- at whole chapters required to be rewritten, ly a page could pass without some material or addition. This labor has occupied the sely, and he has performed it conscien- o that the book may be considered a faith- lture of an exceptionally wide clinical e in infantile diseases, corrected by a care- of the recent literature of the subject.— *Surg. Reporter*, April 5, 1879.

rcely necessary for us to say the work be- a standard work upon diseases of children, work has a higher standing than it upon ions. In consequence of its thorough re- work has been made of more value than may be regarded as fully abreast of the e cordially commend it to students and There is no better work in the language of children.—*Cincinnati Med. News*, 9.

hor has evidently determined that it shall ound in the esteem of the profession for e latest knowledge on that important of medicine. He has accordingly in- in the present edition the useful and sults of the latest study and experience, can and foreign, especially those bearing atics. Altogether the book has been proved, while it has not been greatly in size.—*New York Medical Journal*,

This excellent work is so well known that an ex ended notice at this time would be superfluous. The author has taken advantage of the demand for another new edition to revise in a most careful manner the entire book; and the numerous corrections and additions evince a determination on his part to keep fully abreast with the rapid progress that is being made in the knowledge and treatment of children's diseases. By the adoption of a somewhat closer type, an increase in size of only thirty pages has been necessitated by the new subject matter introduced.—*Boston Med. and Surg. Jour.*, May 29, 1879.

Probably no other work ever published in this country upon a medical subject has reached such a heighth of popularity as has this well-known treatise. As a text and reference-book it is pre-eminently the authority upon diseases of children. It stands deservedly higher in the estimation of the profession than any other work upon the same subject.—*Nashville Journ. of Med. and Surg.*, May, 1879.

The author of this work has acquired an immense experience as physician to three of the large charities of New York in which children are treated. These asylums afford unsurpassed opportunities for observing the effects of different plans of treatment, and the results as embodied in this volume may be accepted with faith, and should be in the possession of all practitioners *now*, in view of the approaching season when the diseases of children always increase. —*Nat Med. Review*, April, 1879.

RIGBY'S SYSTEM OF MIDWIFERY. With notes and Additional Illustrations. Second American edition. One volume octavo, cloth 422 pages, $2 50.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American, from the second revised and enlarged English edition. In one handsome octavo volume, cloth, $2 50.

THOMAS (T. GAILLARD), M.D.,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. F edition, enlarged and thoroughly revised. In one large and handsome octavo vo 800 pages, with 191 illustrations. Cloth, $5 00; leather, $6 00. (*Just Issued.*)

A work which has reached a fourth edition, and that, too, in the short space of five years, has achieved a reputation which places it almost beyond the reach of criticism, and the favorable opinions which we have already expressed of the former editions seem to require that we should do little more than announce this new issue. We cannot refrain from saying that, as a practical work, this is second to none in the English, or, indeed, in any other language. The arrangement of the contents, the admirably clear manner in which the subject of the differential diagnosis of several of the diseases is handled, leave nothing to be desired by the practitioner who wants a thoroughly clinical work, one to which he can refer in difficult cases of doubtful diagnosis with the certainty of gaining light and instruction. Dr. Thomas is a man with a very clear head and decided views, and there seems to be nothing which he so much dislikes as hazy notions of diagnosis and blind routine and unreasonable therapeutics. The student who will thoroughly study this book and test its principles by clinical observation, will certainly not be guilty of these faults.—*London Lancet*, Feb. 13, 1875

Reluctantly we are obliged to close this unsatisfactory notice of so excellent a work, and in conclusion would remark that, as a teacher of gynæcology, both didactic and clinical, Prof. Thomas has certainly taken the lead far ahead of his *confrères*, and as an author he certainly has met with unusual and merited success.—*Am Journ. of Obstetrics*, Nov. 1874.

This volume of Prof. Thomas in its revised form is classical without being pedantic, full in the of anatomy and pathology, without po translation of pages of German literature, d distinctly the details and difficulties of eac tion, without wearying and useless minuti in all respects a work worthy of confidence, ing the high regard in which its distingui thor is held by the profession.—*Am. Sup Obstet. Journ.*, Oct. 1874.

Professor Thomas fairly took the Professi United States by storm when his book first appearance early in 1868. Its reception wa enthusiastic, notwithstanding a few adve cisms from our transatlantic brethren, the f edition was rapidly exhausted, and in six second one was issued, and in two years a was announced and published, and we are mised the fourth. The popularity of this not ephemeral, and its success was unprec the annals of American medical literature. is a long period in medical scientific re Thomas's work on "Diseases of Women" is leading native production of the United St order, the matter, the absence of theoretica tiveness, the fairness of statement, and the of diction, preserved throughout the entire the book, indicate that Professor Thom overestimate his powers when he conceive and executed the work of producing a ne upon diseases of women.—PROF. PALLEN, *wille Med. Journal*, Sept. 1874.

BARNES (ROBERT), M.D., F.R.C.P.,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND S CAL DISEASES OF WOMEN. Second American, from the Second Enlarged an English Edition. In one handsome octavo volume, of 784 pages, with 181 illu Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

The call for a new edition of Dr. Barnes's work on the Diseases of Females has e the author to make it even more worthy of the favor of the profession than before. B rangement and careful pruning space has been found for a new chapter on the Gyn Relations of the Bladder and Bowel Disorders, without increasing the size of the bo many new illustrations have been introduced where experience has shown them to be ne is therefore hoped that the volume will be found to reflect thoroughly and accurately the condition of gynæcological science.

Dr Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

We pity the doctor who, having any considerable practice in diseases of women, has no copy of "Barnes" for daily consultation and instruction. It is at once a book of great learning, research, and individual experience, and at the same time eminently practical. That it has been appreciated by the profession, both in Great Britain and in this country, is shown by the second edition following so soon upon the first.—*Am. Practitioner*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 628 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should b consulted by the profession.—*Am. Supp Journ. Gt. Britain and Ireland*, Oct. 1878.

No other gynæcological work holds a hi tion, having become an authority every diseases of women. The work has been fully abreast of present knowledge. Eve tioner of medicine should have it upon the of his library, and the student will find it a text-book.—*Cincinnati Med. News*, Oct. 1

This second revised edition, of course, de the commendation given to its predecessor, additional one that it appears to include all all the additions to our knowledge of its su have been made since the appearance of the tion. The American references are, for an work, especially full and appreciative, and cordially recommend the volume to Ameri ers.—*Journ. of Nervous and Mental Di* 1878.

This second edition of Dr. Barnes's gre comes to us containing many additions and i ments which bring it up to date in every The excellences of the work are too well k require enumeration, and we hazard the p that they will for many years maintain its sition as a standard text-book and guide students and practitioners.—*N. C. Med.* Oct. 1878.

CHADWICK (JAMES R.), A.M., M.D.

E PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the

se of Students and Practitioners of Medicine. Second Edition. Thorougly Revised. n one large and very handsome octavo volume of 875 pages, with 133 illustrations. loth, $5; leather, $6; half Russia, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

nusually rapid exhaustion of a large edition of this work, while flattering to the author idence that his labors have proved acceptable, has in a great measure heightened his responsibility. He has therefore endeavored to take full advantage of the opportunity to him for its revision. Every page has received his earnest scrutiny; the criticisms viewers have been carefully weighed; and while no marked increase has been made in of the volume, several portions have been rewritten, and much new matter has been In this minute and thorough revision, the labor involved has been much greater than s apparent in the results, but it has been cheerfully expended in the hope of rendering more worthy of the favor which has been accorded to it by the profession.

ountry of the world has gynæcology re- reattention than in America. It is, then, lisg of pleasure that we welcome a work s of women from so eminent a gynæcolo- Emmet, and the work is essentially clini- ves a strong impress of the author's in- y. To criticize, with the care it merits, hroughout, would demand far more space our command. In parting, we can say ork teems with original ideas, fresh and methods of practice, and is written in a elegant style, worthy of the literary repu- e country of Longfellow and Oliver Wen- .—*Brit. Med. Journ*, Feb. 21, 1880.

ecological treatise has appeared which n equal amount of original and useful or does the medical and surgical history include a book more novel and useful. r and statistical information which it marvellous, both in quantity and accu- annot be otherwise than invaluable to stigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med. Gaz.*, April 6, 1880.

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz.*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

AN (J. MATTHEWS), M.D., LL.D., F.R.S.E., etc.

INICAL LECTURES ON THE DISEASES OF WOMEN,

livered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 es. Cloth, $1 50. (*Just Ready.*)

is every way worthy of their author; look upon them as among the most valu- contributions. They are all upon mat- est interest to the general practitioner. m deal with subjects that are not, as a ately handled in the text-books; others hile bearing upon topics that are usually at length in such works, yet bear such a individuality that, if widely read, as they deserve to be, they cannot fail to exert a restraint upon the undue eagerness with y young physicians seem bent upon fol- wild teachings which so infest the gynæ- the present day.—*N. Y. Med. Journ.*, .

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsonud character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

SBOTHAM (FRANCIS H.), M.D.

E PRINCIPLES AND PRACTICE OF OBSTETRIC MEDI-

E AND SURGERY, in reference to the Process of Parturition. A new and enlarged ion, thoroughly revised by the author. With additions by W. V. KEATING, M. A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWI

Third American edition, revised by the author. Edited, with additions, by Ro Harris, M.D. In one handsome octavo volume of about 700 pages, with ne illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready*)

EXTRACT FROM THE AUTHOR'S PREFACE.

The second American edition of my work on Midwifery being exhausted before th sponding English edition, I cannot better show my appreciation of the kind reception has received in the United States than by acceding to the publisher's request that I myself undertake the issue of a third edition. As little more than a year has elap the second edition was issued, there are naturally not many changes to make, but nevertheless, subjected the entire work to careful revision, and introduced into it a most of the more important recent additions to obstetric science. To the operation o elytrotomy—formerly described along with the Cæsarean section—I have now devote rate chapter. The editor of the Second American edition, Dr. Harris, enriched it w valuable notes, of which, it will be observed, I have freely availed myself.

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy. The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence*, we would undoubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all d necessary for a full understanding of the s omitted.—*Cincinnati Med. News*, Jan. 18

The rapidity with which one edition of follows another is proof alike of its exce of the estimate that the profession has fo It is indeed so well known and so high that nothing need be said of it as a w things considered, we regard this treatise best on Midwifery in the English langua *Medical Journal*, May, 1880

It certainly is an admirable exposit Science and Practice of Midwifery. Of additions made by the American editor, Harris, who never utters an idle word, studious researches in some special dep obstetrics are so well known to the pro of great value.—*The American Practitio* 1880

and that it numbers among its contributors the distinguished names of Lombe Atthil Aveling, Robert Barnes, J. Henry Bennet, Nathan Bozeman, Thomas Chambers, wood Churchill, Charles Clay, John Clay, J. Matthews Duncan, Arthur Farre, Greenhalgh, W. M. Graily Hewitt, J. Braxton Hicks, William Leishman, A donald, Alfred Meadows, Alex. Simpson, J. G. Swayne, Lawson Tait, Edward E. H. Trenholme, T. Spencer Wells, Arthur Wigglesworth, and many othe guished practitioners. Under such auspices it has amply fulfilled its object of pres the physician all that is new and interesting in the rapid development of obstetrical a cological science.

As a very large increase in the subscription list is anticipated under this reduction gentlemen who propose to subscribe, and subscribers intending to renew their subs are recommended to lose no time in making their remittances, as the limited number may at any time be exhausted.

SHMAN (*WILLIAM*), *M.D.*,

Regius Professor of Midwifery in the University of Glasgow, &c.

SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF

REGNANCY AND THE PUERPERAL STATE. Third American edition, revised by e Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia ospital, &c. In one large and very handsome octavo volume, of 733 pages, with over wo hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

orks on this subject have met with as great d as this one appears to have. To judge equency with which its author's views are and its statements referred to in obstetrical , one would judge that there are few phy- voting much attention to obstetrics who ut it. The author is evidently a man of rience and conservative views, and in no f medicine are these more valuable than in *e Remedies*, Jan. 1880.

lly welcome the new edition of this excel- -book of midwifery. The former editions a most favorably received by the profes- th sides of the Atlantic. In the prepara- present edition the author has made such s as the progress of obstetrical science require, and we cannot but admire the h which the task has been performed. r it an admirable text-book for students ir attendance upon lectures, and have re in recommending it. As an exponent wifery of the present day it has no supe- rior in the English language.—*Canada Lancet*, Jan. 1880.

The book is greatly improved, and as such will be welcomed by those who are trying to keep posted in the rapid advances which are being made in the study of obstetrics.—*Boston Med. and Surg Journ.*, Nov 27, 1879.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise. To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

RY (*JOHN S.*), *M.D.*,

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition. Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (SAMUEL D.), M.D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

SYSTEM OF SURGERY: Pathological, Diagnostic, Ther

and Operative. Illustrated by upwards of Fourteen Hundred Engravings. Fift carefully revised, and improved. In two large and beautifully printed imperial oc umes of about 2300 pp., strongly bound in leather, with raised bands, $15; half raised bands, $16.

The continued favor, shown by the exhaustion of successive large editions of this gr proves that it has successfully supplied a want felt by American practitioners and stud the present revision no pains have been spared by the author to bring it in every res up to the day. To effect this a large part of the work has been rewritten, and the w arged by nearly one-fourth, notwithstanding which the price has been kept at its for moderate rate. By the use of a close, though very legible type, an unusually large a matter is condensed in its pages, the two volumes containing as much as four or five octavos. This, combined with the most careful mechanical execution, and its very dur ing renders, it one of the cheapest works accessible to the profession. Every subject belonging to the domain of surgery is treated in detail, so that the student who po work may be said to have in it a surgical library.

We have now brought our task to a conclusion, and have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together, that the busy practitioner, when in difficulty, can at once find the information he requires. His work, on the contrary, is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm "*Primus inter Pares.*" It is learned, schol thodical, precise, and exhaustive. We sca any living man could write so complete and treatise, or comprehend more solid, instruct in the given number of pages. The labor been immense, and the work gives eviden powers of mind, and the highest order of disciplino and methodical disposition, and an of acquired knowledge and personal experi *Med. Journ.*, Feb. 1873.

As a whole, we regard the work as the rep "System of Surgery" in the English lan *Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us a complete view of the surgical knowledge Some years ago we had the pleasure of pr first edition of Gross's Surgery to the pr work of unrivalled excellence; and now w result of years of experience, labor, and stu densed upon the great work before us. An or practitioners desirous of enriching their a treasure of reference, we can simply c purchase of these two volumes of immens *Cincinnati Lancet and Observer*, Sept. 187

A complete system of surgery—not a m of operations, but a scientific account of su and practice in all its departments.—*Br Med. Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJU

and Malformations of the Urinary Bladder, the Prostate Gland, and the Ureth Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., S the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with trations: cloth, $4 50. (*Just Issued.*)

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med.* 1876.

It is with pleasure we now again take work in a decidedly new dress. Indeed, it garded as a new book in very many of its chapters on "Diseases of the Bladder," Body," and "Lithotomy," are splendid descriptive writing; while the chapter on is one of the most concise and clear that we read.—*New York Med. Journ.*, Nov. 1876.

Ashhurst's Surgery is too well known in this country to require special commendation from us. This, its second edition, enlarged and thoroughly revised, brings it nearer our idea of a model text-book than any recently published treatise. Though numerous additions have been made, the size of the work is not materially increased. The main trouble of text-books of modern times is that they are too cumbersome. The student needs a book which will furnish him the most information in the shortest time. In every respect this work of Ashhurst is the model text-book—full, comprehensive and compact.—*Nashville Jour. of Med. and Surg.*, Jan. '79.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

NT (*THOMAS*), *F.R.C.S.*,

rgeon to Guy's Hospital.

PRACTICE OF SURGERY.

Second American, from the Sec-
and Revised English Edition. With Six Hundred and Seventy-two Engravings on
d. In one large and very handsome imperial octavo volume of over 1000 large and
ly printed pages. Cloth, $6; leather, $7. (*Just Ready.*)

k has enjoyed the advantage of two thorough revisions at the hand of the author since
ance of the first American edition, resulting in a very notable enlargement of size and
nt of matter. In England this has led to the division of the work into two volumes,
here comprised in one, the size being increased to a large imperial octavo, printed on
d but clear type. The series of illustrations has undergone a like revision, and will
correspondingly improved.

rked success of the work on both sides of the Atlantic shows that the author has suc-
the effort to give to student and practitioner a sound and trustworthy guide in the
f Surgery; while the simultaneous appearance of the present edition in England and
untry affords to the American reader the benefit of the most recent advances made
surgical science.

so many text-books of surgery, so many
skilled and distinguished hands, that to ob-
or of a third edition in England is no light
Bryant merits this, by clearness of style,
dgment in selecting the operations he re-
in his new editions he goes carefully over
unds, in light of later research. On these
allied points, Mr. Bryant is a calm and un-
server, and his book throughout has the
of maintaining the true scientific, judicial
d.—*Med. and Surg. Reporter*, March 22,

k before us is the American reprint of the
edition, and has the advantage over the
g of more convenient size, and in being
into one volume. The author has rewrit-
ter part of the work, and has succeeded,
nt of new matter added, in making it mark-
tive from previous editions. A few extra
been added, and also a few new illustrations
The publishers have presented the work
le style. As a concise and practical manual
rgery it is perhaps without an equal, and
always be a favorite text-book with the
practitioner.—*N. Y. Med. Record*, March

Another edition of this manual having been called for, the author has availed himself of the opportunity to make no few alterations in the substance as well as in the arrangement of the work, and, with a view to its improvement, has recast the materials and revised the whole. We ourselves are of the opinion that there is no better work on surgery extant.—*Cincinnati Med. News*, March, 1879.

Bryant's Surgery has been favorably received from the first, and evidently grows in the esteem of the profession with each succeeding edition. In glancing over the volume before us we find proof in almost every chapter of the thorough revision which the work has undergone, many parts having been cut out and replaced by matter entirely fresh.—*N. Y. Med. Journ.*, April, 1879.

Welcome as the new edition is, and as much as it is entitled to commendation, yet its appearance at this time is, in a certain sense, a matter of regret, as it will be in competition with another work, lately issued from the same press. But, the difficult task of forming a judgment as to the relative merits of Bryant and Ashhurst we will not attempt, but predict that, considering the high excellence of both, many others will likewise be forced to hesitate long in making choice between them.—*Cincinnati Lancet and Clinic*, March 22, 1879.

ERICHSEN (JOHN E.),

Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise
gical Injuries, Diseases, and Operations. Carefully revised by the author
Seventh and enlarged English Edition. Illustrated by eight hundred and sixty
gravings on wood. In two large and beautiful octavo volumes of nearly
cloth, $8 50 ; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

In revising this standard work the author has spared no pains to render it worthy of
ance of the very marked favor which it has so long enjoyed, by bringing it thoro
level with the advance in the science and art of surgery made since the appear
last edition. To accomplish this has required the addition of about two hundred
while the illustrations have undergone a marked improvement. A hundred and fifty
wood-cuts have been inserted, while about fifty other new ones have been substituted
which were not deemed satisfactory. In its enlarged and improved form it is ther
sented with the confident anticipation that it will maintain its position in the fr
text-books for the student, and of works of reference for the practitioner, while its ex
moderate price places it within the reach of all.

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am Practitioner*, April, 1878.

It is no idle compliment to say that this is the best edition Mr. Erichsen has ever produced of his well-known book. Besides inheriting the virtues of its predecessors, it possesses excellences quite its own. Having stated that Mr. Erichsen has incorporated into this edition every recent improvement in the science and art of surgery, it would be a supererogation to give a detailed criticism. In short, we unhesitatingly aver that we know of no other single work where the student and practitioner can gain at once so clear an insight into the principles of surgery, and so complete a knowledge of the exigencies of surgical practice.—*London Lancet*, Feb. 14, 1878

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

Of the many treatises on Surgery which
our task to study, or our pleasure to read,
which in all points has satisfied us so well
treatise of Erichsen. His polished, clear
dom from prejudice and hobbies, his unsur
of his subject, and vast clinical experience
admirably to write a model text-book. W
at the least cost of time, to learn the most
surgery, we turn, by preference, to his
pleasure, therefore, to see that the appreci
general, and has led to the appearance of
tion.—*Med. and Surg. Reporter*, Feb. 2,

Notwithstanding the increase in size,
much old matter has been omitted. The
has been thoroughly written up, and not
ed by a few extra chapters. A great im
been made in the illustrations. One hun
new ones have been added, and many of
have been redrawn. The author highly
favor with which his work has been recei
can surgeons, and has endeavored to ren
edition more than ever worthy of their
he has succeeded admirably, must, we
general opinion. We heartily recomme
both student and practitioner.—*N. Y.*
Feb. 1878.

Erichsen has stood so prominently
years as a writer on Surgery, that his
world wide, and his name is as famili
ical student as to the accomplished and
surgeon. The work is not a reprint
tions, but has in many places been
ten. Recent improvements in surgery
caped his notice, various new operatio
thoroughly analyzed, and their merits
discussed. One hundred and fifty ne
add to the value of this work.—*N. O.*
Journal, March, 1878.

HOLMES (TIMOTHY), M.D.,

Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE. In o
some octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6;
half Russia, $7 50. (*Just Issued.*)

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med.*
14, 1876.

It will be found a most excellent
gery by the general practitioner who
time to give attention to more minute
works and to the medical student. In
of no one we can more cordially reco
author has succeeded well in giving
practical account of each surgical inj
ease, and of the treatment which is
monly advisable. It will no doubt
lar work in the profession, and especial
book.—*Cincinnati Med. News*, April,

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the fourth and enlarged London Edition. With illustrations. In one 8vo. vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTH
TIONS OF MINOR SURGERY. *New*

MILTON (FRANK H.), M.D.,

Professor of Fractures and Dislocations, &c., in Bellevue Hosp. Med. College, New York.

PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. Fifth edition, revised and improved. In one large and handsome octavo volume of nearly 800 pages, with 344 illustrations. Cloth, $5 75; leather, $6 75. (*Lately Issued.*)

is no better work on the subject in existence
t of Dr. Hamilton. It should be in the posses-
every general practitioner and surgeon.—*The*
rn. of Obstetrics, Feb. 1876.

lue of a work like this to the practical physi-
surgeon can hardly be over-estimated. and the
of having such a book revised to the latest
merely on account of the practical importance

of its teachings, but also by reason of the medico-legal bearings of the cases of which it treats, and which have recently been the subject of useful papers by Dr. Hamilton and others, is sufficiently obvious to every one. The present volume seems to amply fill all the requisites. We can safely recommend it as the best of its kind in the English language, and not excelled in any other.—*Journ. of Nervous and Mental Disease*, Jan. 1876.

TTLESHIP (EDWARD), F.R.C.S.,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

NUAL OF OPHTHALMIC MEDICINE. In one royal 12mo. volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

ok is written in a careful and logical man-
though extremely concise, we have failed
any evidence of ambiguity. It is rendered
pact and homogeneous by frequent refer-
y page number, to other portions of the
petitions are thus avoided, and we have
prised to find how much information our
as succeeded in conveying in so small a
careful study of the book will well repay
l practitioner, even though it should
y as a *monitor*. It is particularly useful
tter regard, as the subject of treatment is
in a thoroughly conservative manner.—
Record, March 6, 1880.

hor has succeeded in touching upon about
nts, operations, diseases of the eye in
general diseases, and has prepared a very
book.—*Cincinnati Lancet and Clinic*,
0.

ltum in parvo, containing all the leading
remembered in the pathology, descrip-
treatment of diseases of the eye. It will
pecially valuable in preparing for exam-
Practitioners will find it convenient as a
ference, when they wish to refresh their

memories in respect to the features of some affections.—*Cincinnati Med. News*, Jan 1880.

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr. Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

A careful examination has convinced us that it is the best work of its class that has come to our notice. While all matter is condensed to the utmost, there are few points that are obscured thereby, and all are rendered really attractive to the average student. We can only hope that every medical student shall be compelled to master the entire volume ere receiving his degree. General practitioners who take care of eye cases would do well to refresh their memories by its careful study.—*Detroit Lancet*, April, 1880.

TER (R. BRUDENELL), F.R.C.S.,

Ophthalmic Surgeon to St. George's Hospital, etc.

RACTICAL TREATISE ON DISEASES OF THE EYE. Edit-
, with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one
adsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75. (*Just*
ued.)

great pleasure that we can endorse the work
valuable contribution to practical ophthal-
r. Carter never deviates from the end he has
nd presents the subject in a clear and concise
easy of comprehension, and hence the more
. We would especially commend, however, as
f high praise, the manner in which the thera-
f disease of the eye is elaborated, for here the
particularly clear and practical, where other
e unfortunately too often deficient. The final

chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

LLS (J. SOELBERG),

Professor of Ophthalmology in King's College Hospital, &c.

REATISE ON DISEASES OF THE EYE. Third American,
om the Fourth London Edition. Thoroughly revised by Chas. S. Bull, M.D., Clinical
rofessor of the Eye and Ear in the Women's Medical College of New York. Illustrated
ith numerous engravings on wood, and six colored plates. Together with selections
om the Test-types of Jaeger and Snellen. In one large and very handsome octavo
olume. (*Preparing.*)

WNE (EDGAR A.),

Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

W TO USE THE OPHTHALMOSCOPE. Being Elementary In-
structions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustra-
tions. In one small volume royal 12mo. of 120 pages: cloth, $1. (*Now Ready.*)

CE'S HANDY-BOOK OF OPHTHALMIC
RY, for the use of Practitioners. Second
, revised and enlarged. With numerous
rations. In one very handsome octavo vol-
, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT, AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A , M.D.,

Aural Surg. to the Presb. Hosp., Surgeon-in-charge of the Infr. for Dis. of the Ear,

THE EAR, ITS ANATOMY, PHYSIOLOGY, AND DISE

A Practical Treatise for the Use of Medical Students and Practitioners. In
some octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50;
$5 50; half Russia, $6 00. (*Now Ready.*)

Recent progress in the investigation of the structures of the ear, and advances ma modes of treating its diseases, would seem to render desirable a new work in which al sources of the most advanced science should be placed at the disposal of the practitio it has been the aim of Dr. Burnett to accomplish, and the advantages which he has e the special study of the subject are a guarantee that the result of his labors will prove to the profession at large, as well as to the specialist in this department.

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Trölsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work, which as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well
busy practitioner in the pleasure he will de
the agreeable style in which many oth
and mostly unknown subjects are treat
specialist the work is of the highest val
sense of gratitude to Dr. Burnett will, we
proportionate to the amount of benefit he
from the careful study of the book, and a
reference to its trustworthy pages.—
Med. Jour., Aug. 1878.

The book is designed especially for the
dents and general practitioners, and plac
disposal much valuable material. Such
the present one, we think, has long been ne
we may congratulate the author on his
filling the gap. Both student and practiti
study the work with a great deal of be
profusely and beautifully illustrated.—
pital Gazette, Oct. 15, 1877.

Dr. Burnett is to be commended for havi
the best book on the subject in the Englis
and especially for the care and atte
given to the scientific side of the subj
Med. Journ., Dec. 1877.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

POISONS IN RELATION TO MEDICAL JURISPRUDENC

MEDICINE. Third American, from the Third and Revised English Editio
large octavo volume of 850 pages; cloth, $5 50; leather, $6 50. (*Just Issu*

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to leg
tions.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the
of this volume, stores of learning, exp
practical acquaintance with his subject,
beyond what any other living authority
ogy could have amassed or utilized. He
sustained his reputation by the consum
and legal acumen he has displayed in th
ment of the subject-matter, and the result
on Poisons which will be indispensable to
dent or practitioner in law and medicine.—
lin Journ. of Med. Sci., Oct. 1875.

BY THE SAME AUTHOR.

MEDICAL JURISPRUDENCE. Seventh American Edition.

by John J. Reese, M.D., Prof. of Med. Jurisp. in the Univ. of Penn. In
octavo volume of nearly 900 pages. Cloth, $5 00; leather, $6 00. (*Lately*

To the members of the legal and medical profession, it is unnecessary to say anything commendatory of Taylor's Medical Jurisprudence. We might as well undertake to speak of the merit of Chitty's Pleadings.—*Chicago Legal News*, Oct. 16, 1873.

It is beyond question the most attractive as well as most reliable manual of medical jurisprudence published in the English language.—*Am. Journal of Syphilography*, Oct. 1873.

It is altogether superfluous for us to offer anything in behalf of a work on medical jurisprudence by an author who is almost universally esteemed to be the best authority on this specialty in our lan
this point, however, we will say that we
Taylor to be the safest medico-legal auth
low, in general, with which we are acqua
language.—*Va. Clin. Record*, Nov. 1873.

This last edition of the Manual is probab
of all, as it contains more material and is
to the latest views of the author as exp
last edition of the Principles. Dr. Reese,
of the Manual, has done everything to
work acceptable to his medical countrym

ANITY AND ITS TREATMENT: Lectures on the Treatment, edical and Legal, of Insane Patients.

With a Summary of the Laws in force in the nited States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very ndsome octavo volume of 471 pages; cloth, $3 25.

isfies a want which must have been sorely e busy general practitioners of this country. the form of a manual of clinical description rious forms of insanity, with a description de of examining persons suspected of in- We call particular attention to this feature k, as giving it a unique value to the gene- ioner. If we pass from theoretical conside- descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

(HENRY C.).

PERSTITION AND FORCE: ESSAYS ON THE WAGER OF AW, THE WAGER OF BATTLE, THE ORDEAL, AND TORTURE.

Third Revised d Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, 2 50. (*Just Ready.*)

luable work is in reality a history of civi- as interpreted by the progress of jurispru- . . In "Superstition and Force" we have ophic survey of the long period intervening primitive barbarity and civilized enlight- . There is not a chapter in the work that not be most carefully studied, and however sed the reader may be in the science of dence, he will find much in Mr. Lea's vol- which he was previously ignorant. The a valuable addition to the literature of cience.—*Westminster Review*, Jan. 1880.

ppearance of a new edition of Mr. Henry C. Superstition and Force" is a sign that our scholarship is not without honor in its na- ntry. Mr. Lea has met every fresh demand work with a careful revision of it, and the edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration, is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

HE SAME AUTHOR. (*Lately Published.*)

TUDIES IN CHURCH HISTORY—THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION.

In one large royal 12mo. volume of 516 pp.; cloth, $2 75.

story was never told more calmly or with learning or wiser thought. We doubt, indeed, other study of this field can be compared with clearness, accuracy, and power.—*Chicago iner*, Dec. 1870.

Lea's latest work, "Studies in Church History," ustains the promise of the first. It deals with subjects—the Temporal Power, Benefit of , and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

SOLD ONLY BY SUBSCRIPTION.

SYSTEM OF MEDICINE.

BY J. RUSSELL REYNOLDS, M.D.,

Professor of the Principles and Practice of Medicine in University College, London.

WITH NOTES AND ADDITIONS BY

HENRY HARTSHORNE, M.D.,

Late Professor of Hygiene in the University of Pennsylvania.

n three large and handsome royal octavo volumes, containing 3052 closely printed, double-columned pages, with 317 illustrations.

***Price per volume, in cloth,* $5; *in sheep,* $6; *in half Russia, raised bands,* $6 50. *Per set, in cloth,* $15; *sheep* $18; *half Russia,* $19 50.**

ME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.
ME II. (*just ready*) contains DISEASES OF THE RESPIRATORY and CIRCULATORY SYSTEMS.
ME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYS-ES, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE CUTA-OUS SYSTEM.

large size and high price of "Reynolds" having kept it beyond the reach of many practi- in this country who desire to possess it, a demand has arisen for an edition at a price which nder it accessible to all. To meet this demand the present edition has been undertaken. The umes and five thousand pages of the original have, by the use of a smaller type and double , been compressed into three volumes of but little over three thousand pages, clearly and ely printed, and offered at a price which renders it one of the cheapest works ever pre- to the American profession.

ot only is the American edition more convenient and lower priced than the English; it is ter and more complete. Some years having elapsed since the appearance of a portion of k, additions are required to bring up the subjects to the existing condition of science. seases, also, which are comparatively unimportant in England, require more elaborate t to adapt the articles devoted to them to the wants of the American physician; and there nts on which the received practice in this country differs from that adopted abroad. plying of these deficiences has been undertaken by HENRY HARTSHORNE, M.D., late Pro- f Hygiene in the University of Pennsylvania, who has endeavored to render the work to the day, and as useful to the American physician as it has proved to be to his Eng- thren. The number of illustrations has also been largely increased, and no effort spared the typographical execution unexceptionable in every respect.

too much praise can scarcely be given to s book. It is a cyclopædia of medicine y some of the best men of Europe. It is eful information such as one finds frequent n one's daily work; for no one head can arry all the knowledge one needs in gen- nce, and one must re er sometimes to one's As a book of reference it is invaluable. It ith the times. It is clear and concentrated and its form is worthy of its famous pub- —*Louisville Med. News*, Jan. 31, 1880.

olds' System of Medicine" is justly con- the most popular work on the principles and of medicine in the English language. The tors to this work are gentlemen of well- reputation on both sides of the Atlantic. ntleman has striven to make his part of the practical as possible, and the informa- tained is such as is needed by the busy ner.—*St. Louis Med. and Surg. Journ.*, 1880.

artshorne has made ample additions and re- so far, all of which give increased value to me, and render it more useful to the Ameri- actitioner. There is no volume in English literature more valuable, and every pur- will, on becoming familiar with it, congrat- imself on the possession of this vast store- of information, in regard to so many of the with which he should be familiar.—*Gail Med. Journ.*, Feb. 1880.

is no medical work which we have in times ore frequently and fully consulted when per- by doubts as to treatment, or by having un- or apparently inexplicable symptoms pre- to us, than "Reynolds' System of Medicine." its contributors are gentlemen who are as nown by reputation upon this side of the h as in Great Britain, and whose right to with authority upon the subjects about they have written is recognized the world They have evidently striven to make their s as practical as possible, and while these are ally full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

By recent additions made necessary by the onward march of science, and the addition of some diseases, also, which are comparatively unimportant to the English reader, which, in this edition, are treated in that comprehensive and elaborate manner to fully adapt them to the American practitioner, the work is materially enhanced in real value, and is fully brought up to the wants of the day. We feel confident in the assertion, that it will certainly prove as useful to the American physician as it has to his English brethren. We have been able to give but a cursory glance at the first volume, yet we have seen quite enough to assure us of the real intrinsic merit of the work, and would most heartily commend it to the profession. The second and third volume will be issued in the next three or four months, at which time we hope to be able to give a more extended notice of its value and worth. —*So. Practitioner*, Jan. 1880.

We are pleased to notice that the American editor took occasion to comment on and add to a number of the chapters his own and the opinions of other eminent American physicians on the subjects treated of, which adds materially to the well-deserved reputation of this great work. . . From a careful examination we are impressed with the belief that this work gives an excellent presentation of modern British medicine in a full and practical form. In fact, it is a cyclopædia of medicine, the result of the collaboration of the leading men in the profession.—*Cincinnati Lancet and Clinic*, Dec. 13, 1879.

HENRY C. LEA'S SON & CO.—Philadelphia.

NOTICE TO SUBSCRIBERS.

INCREASED INDUCEMENTS FOR 1880.

With a view of increasing the attractions of the "American Journal of the M cal Sciences," and of bringing within the reach of all members of the professio immense amount of information now presented by it and its accessory periodicals, "Medical News and Library" and the "Monthly Abstract," the two latter wi after be merged together, under the name of "The Medical News and Abstr commencing January 1, 1880. The "News and Abstract" will consist of sixty pages per month, handsomely printed, in a neat cover, and will contain all the ma heretofore presented in both periodicals, with the exception of the sixteen pages o "Library Department." Its price will be Two Dollars and a Half per annum, riably in advance, at which rate subscribers will receive nearly *eight hundred large pages per annum*, free of postage.

Not only will this monthly thus be in itself one of the cheapest periodicals offer the profession, but it will be furnished in commutation, without charge, to advance-p subscribers of the "American Journal of the Medical Sciences," the subscripti which will remain, as heretofore, Five Dollars per annum. For this very mod sum, therefore, subscribers will receive two periodicals of the highest class, a Quar and a Monthly, containing in all nearly two thousand pages per annum, stored with choicest original and selected matter that can be furnished by the medical literatu both hemispheres.

These terms may be recapitulated as follows:—

TERMS FOR 1880.

The American Journal of the Medical Sciences, published quarterly (1150 pages per annum), and The Medical News and Abstract, published monthly (768 pages per annum),	Five D per an in adv

SEPARATE SUBSCRIPTIONS TO

The American Journal of the Medical Sciences, when not paid for in advance.	Five Dol

The Medical News and Abstract, invariably in advance, Two Dollars and a Half

---

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, lettered, for binding the volumes of the Journal (two annually) and the News Abstract (one annually), free by mail, on remitting ten cents for each cover.

It is evident that only a very considerable increase to the existing subscriptio will justify the unexampled terms thus offered, by which the equivalent of three or large octavo volumes is furnished, handsomely printed in a form for preservation, for trifling sum of Five Dollars. Gentlemen, therefore, are respectfully requested to no time in remitting their subscriptions to avoid the risk of disappointment from exhaustion of the edition printed; and it is suggested that they may aid in rende the enterprise permanent by kindly communicating to their friends the very great ind ments thus offered.

The safest mode of remittance is by bank check or draft, or postal money order d to the order of the undersigned. Where these are not accessible, remittances for "Journal" and "News and Abstract" may be made at the risk of the publisher forwarding in registered letters. Address

THE
MEDICAL NEWS
AND
ABSTRACT.

A CONSOLIDATION OF THE "MEDICAL NEWS AND LIBRARY" AND THE "MONTHLY ABSTRACT OF MEDICAL SCIENCE."

EDITED BY

I. MINIS HAYS, A.M., M.D.

QUE PROSUNT OMNIBUS.

PHILADELPHIA:
HENRY C. LEA'S SON & CO
1880.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

ntered according to the Act of Congress, in the year 1880, by HENRY C. LEA'S SON & Co., in the Office of the Librarian of Congress. All rights reserved.

BRISTOWE'S PRACTICE—New Edition—Just Ready.

A TREATISE ON THE PRACTICE OF MEDICINE. By John Syer Bristowe, MD, F.R.C.P., Physician and Joint Lecturer on Medicine, St. Thomas's Hospital. Se American edition, revised by the Author. Edited, with additions, by James H. Hu inson, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nea 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; very handsome half Ru $6 50.

The notes and an article on "Hæmophilia," by the American editor, add to the excellent work very valuable information upon matters of particular importance to the American practitioner. In the volume before us, the author and editor have succeeded in a manner which has undoubtedly secured position for the result of their labor of a most gratifying character.—*St. Louis Courier of Medicine*, April, 1880

There is no treatise on the Practice of Medicine which we can recommend with more confidence. The notes and additions by Dr. Hutchinson are of much value, not only adapting the work to our country, but supplying some important material.—*Pacific Med. and Surg. Journ.*, May, 1880.

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically on this side of the water. We see no rea modify the high opinion previously expressed regard to Dr Bristowe's work, except by our appreciation of the careful labors of the in following the lateral growth of medical The chapter on diseases of the skin and of the ous system, with a new one on insanity co from the best sources outside of the author's long experience, and the valuable portion to general pathology, aid greatly in compl exceptionally good book for purposes of re nd instruction.—*Boston Medical and S Journal*, February, 1880.

Among the many manuals of medicine which hitherto issued from the press, student and tioner alike will find his money most pr invested in the purchase, and his time in the of this second edition of Bristowe's The Practice.—*Canadian Journ. of Med. Sci*, M

LEISHMAN'S MIDWIFERY—New Edition—Just Ready.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY THE PUERPERAL STATE. By William Leishman, M.D., Regius Professor wifery in the University of Glasgow, etc. Third American edition, revised by the with additions by John S. Parry, M.D., Obstetrician to the Philadelphia H In one large and very handsome 8vo. volume of 733 pages, with over 200 illustr cloth, $4 50; leather, $5 50; very handsome half Russia, $6.

It is a book in which not only the student may put his faith, but one which may be studied with profit by the practitioner. Up to the present writing, we know of no similar volume which can more conscientiously be recommended to the favorable consideration of the profession.—*Quarterly Epitome*, Mar. 1880.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic. In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have a great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

The book is greatly improved, and as suc welcomed by those who are trying to keep the rapid advances which are being mad study of obstetrics.—*Boston Med. and Surg.* Nov. 27, 1879.

To the American student the work before prove admirably adapted, complete in all essentially modern in its teachings, and onstrations noted for clearness and pr will gain in favor, and be recognized as a standard merit. The work cannot fail to lar, and is cordially recommended.—*N. O. Surg. Journ.*, March, 1880.

Leishman's is certainly one of the best sy works on midwifery. It is very complete parts essential for such a treatise. To prac and students it is to be strongly recomm a safe and reliable guide to the modern pr midwifery.—*Canada Med. and Surg.* March, 1880.

PLAYFAIR'S MIDWIFERY—New Edition—Just Ready.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY. By W. S. fair, M.D., F.R.C.P., Professor of Obstetric Medicine in King's College, etc. etc. American edition, revised by the author. Edited, with additions, by Robert P. M.D. In one handsome octavo volume of about 700 pages, with nearly 200 illust Cloth, $4; leather, $5; very handsome half Russia, $5 50.

The third edition—so soon following the second—shows that the good qualities of the book have been recognized by the profession. The second American has been exhausted before the second English edition, and this is therefore especially prepared and revised by the author for this country; a fact which ought to be satisfactory as to the profession here being furnished with the latest work upon all subjects pertaining to obstetrics.—*Am. Journ. of Med. Sci.*, April, 1880.

The favorable reception of former editions of this work in this country, has induced the author to make a careful revision of this, the third edition, the practical value of which is enhanced by the notes and additions of the well-qualified American editor. The work is cordially recommended to all in need of a really practical book on obstetrics.—*Med. Monthly*, June, 1880.

The rapidity with which one edition of th follows another is proof alike of its excel of the estimate that the profession has form It is indeed so well known and so highly that nothing need be said of it as a whol things considered, we regard this treatise very best on Midwifery in the English lang *N. Y. Medical Journal*, May, 1880.

It certainly is an admirable exposition Science and Pathology of Midwifery. Of additions made by the American editor, Dr Harris, who never utters an idle word, and studious researches in some special depart obstetrics are so well known to the profe of great value.—*The Am. Practitioner*, April,

CLINICS.

Clinical Lectures.

THE SUMMER DISEASES OF THE SKIN, AND THEIR TREATMENT.

INICAL LECTURE DELIVERED AT RUSH MEDICAL COLLEGE, CHICAGO, JUNE 4, 1880.

By JAMES NEVINS HYDE, M.D.,
PROFESSOR OF SKIN AND VENEREAL DISEASES.

TLEMEN: I desire to describe this morning certain disorders of kin occurring most frequently in this latitude during the season of er, and to make some suggestions respecting their treatment. But roper to remark at the outset, that the occurrence of such disorders strictly confined to what we are accustomed to call the "heated " With our artificial habits of life, a severe erythema may be in- by heat in midwinter equally with an attack of cholera morbus the ingestion of unripe fruit. It is also true that there are disorders skin which seem to be greatly benefited by the advent of hot weather, isappear then, to return with the early part of the ensuing season.

title of our subject introduces us at once to questions of etiology. ummer disorders of the skin should be those influenced by solar or by agencies which that heat arouses to activity. Yet ignorance, lice, and even the speculations of science still strive to show that affections are real eruptions—"breakings out" upon the surface of dy of morbid humors in the fluids which circulate beneath. The who labours long over her washtub on a hot summer day and a rash upon the skin, still comes to the dispensary asking for hing to "cleanse her blood." She, and those who agree with her, e correct in their views, but, until they can demonstrate to us the nature of the supposed changes effected in the blood, you and I e content with studying the more tangible sources of the diseases e at present to consider.

, it is true that the inhabitants of tropical countries suffer rather from skin diseases than do those who live in colder latitudes; but the difference is not so great as is commonly supposed. Certainly the vegetable parasites flourish best in high temperatures; but you will more acne-sprinkled faces in London and New York than in Havana St. Paul de Loanda. It is really the sudden changes from cold to h which influence sensitive skins among Americans. In some parts of country the temperature ranges annually through 150° F. It is the s inured to the severe cold of our Northern winter which reacts patholo cally beneath the rays of the summer sun. Under these circumstan imperfectly anointed by its natural unguent, subjected to various exte irritants, and hastily summoned to a profuse diaphoresis, it responds i series of interesting phenomena.

The stimulating influence of heat, when applied to the surface of body, is usually first announced by an increase in the quantity of secretion poured out by the sudoriferous glands. This secretion is signed, as you know, to accomplish several ends; and among these is reduction of the temperature of the body by evaporation. Altho sensible and insensible perspiration are not in ordinary states irritatin the sound skin, they yet may prove so to the congested or inflamed s and that probability is immensely increased when the sweat is chemic altered and mingled with a foul-smelling sebum. You have seen a si difference between the action of healthy and ammoniacal urine in co with the integument. Suppose that we add to the concurrent effec heat and moisture, the influence of friction. Friction upon the surf the body, either by articles of clothing or contiguous portions of skin only stimulates the action of the glands, but also, as I have heret shown, actually increases the temperature of the part to which it is ap Let us now suppose that these three important agencies coöperate production of their effects upon an integument long uncleansed by abl supported by an abundant cushion of fat, and exposed in the adve of active toil. We shall then have a picture of the most fruitful fiel the study of the effects we have in view.

We should naturally look for these effects upon those parts of the su most exposed to the sun's rays; those best supplied with large-sized gl those most frequently in contact with similar parts or with the cloth and those where the disposition of the latter or the postures of the most favour the accumulation of secretions. Such parts are the uncov face, wrists, and hands; the little pockets behind the ears; the beneath the chin and at the back of the neck; the hollows about clavicles; the axillary and ano-genital regions; the interscapular interdigital spaces; the vulvo-femoral and the scroto-femoral angles; faces of the thighs which are in contact superiorly; the flexures of joints; and the larger or smaller spaces covered by the breast of female as it lies upon the surface of the thorax. The symmetrical di bution of disease in some of these regions is a curious and beautiful tration of the causes operating to produce it. Thus it is not rare to an erythematous blush sweeping from the perineum down upon the i face of one thigh, its margin sufficiently distinct to be traced with a and the whole exactly reproduced upon the corresponding face of the limb.

But there are other causes which we must not fail to consider as op tive in the summer season. Many of the inhabitants of our larger

---

[1] On the Non-Venereal Cutaneous Affections, etc. Boston Med. and Surg. Jo June 27, 1878, p. 824.

are accustomed, at this period of the year, to resort for recreation to the
mountains, the seaside, and the forests, and to engage in the unwonted
ctivities of an out-door life—health-giving to the many, but with preju-
icial results to the few who at all times are prone to excesses. In one
egion, the shell-fish when eaten are capable of producing urticaria; the
nats and mosquitos of the favourite resorts of sportsmen in the North-
est inflict wounds which result in severe inflammation of exposed sur-
ces; the rays of the sun, aided by vivid reflection from the surface of
ater, exhibit their effects in those diffuse and localized pigmentations
nown as "tan" and "freckles;" and, in city or country, the improper
e of alcoholic beverages may stimulate the perspiratory secretion to the
rge of follicular congestion. Pedestrians in the fields and woods may
me in contact with the poison ivy (*Rhus toxicodendron*), and thus beget
eczematoid affection. Coarse, dyed flannel underclothing next the
in, a truss, a suspensory bag, a waistband or corsets, worn with impunity
winter, may beget trouble on a hot summer day; and this is true of a
g list of predisposing or exciting causes, which at other seasons are
ppreciated or inoperative. The restless, teething baby during a hot
ht becomes covered with a lichenoid rash; the preputial sac of an adult
le, which has tolerated well its sebaceous secretions in the month of
nuary, will often rebel with a balanitis or herpes in July; and the ano-
ital region at all ages is none the less sensitive in hot weather. The
te swallowed in one month with happiest effect, in another produces
ofuse diaphoresis or an intolerable pruritus; and the diabetic, rheu-
ic, and malarial disorders are most often the sources of disagreeable
ing when the temperature of the air is increased. A young woman,
ged throughout the winter with impunity in sewing up rents in the
y bags of the United States mail, showed me lately an eczema of the
ds which appeared during the hot weeks of the past month. The palm
the left hand and the fingers adjoining gave an exact tracing of the
nner in which each bag had been seized, and the fingers of the right
mber showed equally well the points of contact where the needle was
d and pushed. Do not forget the vivacity and pertinacity of the animal
asites under the stimulus of heat; and that the self-inflicted wounds by
finger-nail in scratching are most potent for evil when aggravated by
y of the causes we are considering. Never commit the blunder of
ting a patient for "prickly heat" or "disorder of the blood," who has
n the bed-fellow of a colony of bugs.

Now the effects produced by these and many other agencies which might
named, whether we call them "hives," "rashes," "itches," "prickly
at," or by other popular terms, are readily assignable to pathological
sses. They are either, first, affections of the skin proper, congestive or
dative; or, secondly, affections of the secreting apparatus of the skin,
hibited in congestion or exudation in and about the follicular walls, and
ompanied by disturbance of function (alteration, suppression, or pro-
ion of discharge); or, third, they are anomalies of pigmentation. All
se may be coincident or successive phenomena, the result being pro-
rtioned to the intensity and endurance of the cause; the degree of
mperature and the nature of the media by which it is conveyed to the
in; the susceptibility of the individual; and the extent of surface in-
lved.

Hyperæmic conditions are all characterized by their redness, varying
om a rosy pink to an empurpled hue—whence the name, erythema—

occurring in diffuse, punctate, or macular lesions (split-pea, finger-nail-sized, etc.), scarcely elevated above the level of the normal integument, and accompanied by subjective sensations of heat, tenderness, itching, smarting, or intense burning. They usually terminate in a few days by epithelial desquamation, the effete epidermis often first exhibiting numerous minute cracks or furrows, through which the red, tender, and newly formed epidermis appears.

According to Hebra, hyperæmia of a transitory character is induced in the skin by temperatures above 100° F.; but beyond 165° F. the erythema does not disappear at once when the source of the heat is removed, its subsequent history being that just described. At 212° F. there is usually destruction of the epidermis, with vesication and the formation of eschars. I need not add that the congestion is due to engorgement of that delicate plexus of bloodvessels which you can see interlacing just beneath the papillary layer of the corium when you examine a section of the skin with a microscopic objective.

When exudation occurs, it may be acute and transitory, accompanied by disturbance of equilibrium between nerve and blood-supply and muscle, resulting in the formation of evanescent, capriciously-shaped and sized wheals, pinkish and whitish in hue, inducing the well-known pricking, tingling, and stinging sensations which distinguish urticaria. Or, occurring between the apposed surfaces, it may furnish the characteristic ill-smelling secretions of intertrigo. Or the exudation may result in the production of one or several of the forms of eczema (erythematous, vesicular, pustular, papular, squamous), whose career may terminate by the mild sequelæ of desquamation and the formation of light yellowish friable crusts, or by the severer symptoms of eczema rubrum, a raw, tender, and angry looking surface, oozing with serum at numerous points, and covered here and there with its bulkier crusts.

Or, again, the congestive process may be limited to the follicles of the skin, and then we note the sudden occurrence of minute punctate or pin-head-sized papules, with profuse diaphoresis accompanied by pricking, tingling, or burning sensations (*Lichen tropicus*, "prickly heat"). When we examine these little papules with care, we discover that the hyperæmia is rather perifollicular than follicular; and that the projection occurs at the orifice of the duct. In other cases we find an abundant crop of equally small-sized vesicles upon the surface, with limpid or amber-coloured contents (*Miliaria*). In yet another class of cases, still smaller vesicles form, looking like seed-pearls scattered over the horny layer of the epidermis; minute drops of sweat being imprisoned between contiguous layers of the lifeless stratum corneum (*Sudamina*).

Among the anomalies of secretion should be named scanty, profuse, and offensive sweating (*Anidrosis*, *Hyperidrosis*, *Bromidrosis*), the latter, frequently accompanied by chemical alteration of the product of the sebaceous glands. Increase of pigmentation of the surface is a common symptom in both the congestive and exudative disorders; but in the production of both "tan" and "freckles" it is observed in uncomplicated diffuse and circumscribed forms.

You should not fail to remember, lastly, that pruritus, itching of the surface of the skin, may be purely a neurosis; and that it may be unaccompanied by any eruption save that produced by the nails in scratching. Mr. Jonathan Hutchinson, of London, has described a disease which is named by him "summer prurigo,"[1] commencing usually at about the age of puberty, lasting for years with exacerbation in the summer season, affecting by preference the face and upper extremities, and rebellious to treatment. But I am unable to recognize from his descriptions a disease occurring in this country with features sufficient to justify its consideration as a separate malady.

Referring to the subject of treatment, we have merely time to-day to consider briefly the general principles which should guide us in the management of this list of disorders at their onset.

You surely need not be told that an observance of the simplest rules of hygiene furnishes the key to a proper prophylaxis. Attention to the cleanliness of the skin, sponge- and open-air bathing, regulation of clothing nd diet, temperance in the use of alcoholic beverages, daily evacuation f the bowels, a pure air in the sleeping apartment—these are all-important. Extremely sensitive skins require protection from the sun's rays by oves, veils, a "capote," similar to that worn by British officers in India, by dusting the surface, as the face after shaving, with rice-flour or wdered starch. The essential oils are largely used by sportsmen in the orthwest, to protect the face, neck and hands, from the incursions of ects.

Given an inflamed or irritated skin, and the first therapeutic injunction o eliminate the cause of the trouble, and to know what not to do. Too n patients apply to us in great distress, who, strange as it may appear, e been swallowing arsenic, the potassium iodide, and worse proprie- y remedies, by the advice of physicians or personal friends, in order to rify the blood." These all are of positive injury in the disorders we considering, and directly tend to aggravate the complaint. It is often case that a mere suspension of the use of these drugs is followed by ediate relief. There is no internal remedy which will "cure" these eases. An emetic may be useful when the stomach is loaded with nding matters, as in urticaria; a cathartic is usually needful when there constipation or impeded portal circulation, and the refrigerant diuretics, ecially when administered in the popular effervescing waters, are grate- to the palate, if they do not conduce to the relief of the surface con- tion. A solution of the citrate of potassium or the bicarbonate of ium will certainly not prove harmful, if swallowed in medicinal doses the patient who insists on swallowing something.

It is no less important to discover whether the disease has not been gravated by topical applications, stimulated till much physical suffering been endured, by officinal remedies or patented nostrums. I charge you study these symptoms of aggravation. About one-half of all our patients ibit these symptoms, and, once recognized, we are on the high road to best of success in their treatment. Well did Huxley say, that "the ple perish for want of knowledge." Know all that predisposes to, ites, and aggravates, disease, and you need nothing further of the teria medica.

The measures I am about to suggest to you should not be deemed of tle importance in the local treatment of diseases of the skin because y are simple. Show me a crimson-hued, swollen, hot, and tender skin, d I will show you a *noli-me-tangere* quite equal to that which was once e reproach of surgery. Such a skin will usually refuse to be comforted y the most perfect ointment made. A local or general bath of medicated water is preferable, and this at the temperature most grateful to the surface. Remember that cold water is generally followed by a sharp and vivid reaction, that when employed it must be used continuously, and be permitted to evaporate, since water kept in contact with the skin in folded cloths is readily made to serve as a hot fomentation. Tepid and warm water baths are followed by a more or less enduring relaxation of the integument. Hebra medicates the water of the bath by pouring it, in a state of ebullition, upon flour or bruised almonds. In this country it is usual to add to each thirty gallons, about four ounces each of the biborate and bicarbonate of sodium, or a double quantity of either salt alone. It is well to squeeze into the water several times a coarse muslin bag containing a quart or more of common bran, as this imparts a mucilaginous and slightly astringent quality to the fluid. After this, the bag can be dried and used on other occasions, as the custom is in the French bathing houses. Soap is, in general, unnecessary, as the object we have in view is not the cleansing so much as the medication of the surface of the body.

---

[1] Lectures on Clinical Surgery, J. & A. Churchill, London, 1878, p. 126.

Immediately after the bath the skin should be carefully and gently dried with soft, freshly-laundried towels—no harsh rubbing is permissible —and then a dusting-powder applied. Best, and cheapest too, of these is lycopodium. Observe that when I cover the surface of the water in this goblet with a thin layer of the dust, I can plunge my finger to the very bottom of the glass and remove it as dry as when it entered. There is not a drop of moisture clinging to the skin. This valuable property of lycopodium is available when it is desired to protect the skin from its own or foreign accumulations; and it has thus gained great favour among the Germans for use over the ano-genital region of infants, to the exclusion of the articles sold for similar uses in the shops. It can be readily combined with finely-powdered tannin when an astringent effect is desired.

Sometimes, however, it is desirable to make use of a dusting-powder which will supply the anti-pruritic effect of camphor; and this we can order, made of "corn-starch farina," rice flour, bismuth, oxide of zinc, and the ordinary starch of the shops. The chief objection to the starch-containing powders is their tendency to form little rolls or cakes when mingled with sweat and serum. An excellent formula, however, is that of Prof. M'Call Anderson: one ounce of starch, half an ounce of the oxide of zinc, and one drachm and a half of powdered camphor. To be of use, this should be made perfectly impalpable by sifting through millers' bolting cloth, and be kept in a wide-mouthed, stoppered vial, that the pungent aroma of the camphor, which seems to be connected with its anti-pruritic virtue, be not dissipated. A coarsely-triturated powder will decidedly irritate the skin, and patients are apt to find this out for themselves. I had lately in my charge a lady affected with severe intertrigo of the skin beneath two voluminous breasts, who sent for her powder from Italy to London, as she found her chemist there prepared it with the greatest care.

Such powders may be dusted freely over the surface, and also applied on soft, wide-meshed linen rags with which they have been incorporated. These should be well pushed up to the linear abrasion, which usually is the chief source of the secretion when folds of the skin lie in contact. Of course, when these secretions are offensive, a small quantity of the solution of chlorinated soda, or a weak carbolic acid lotion, should be used to correct the odour.

When the surface of the skin does not well tolerate the bath and the powder, it may be soothed with olive oil in various forms, and the most grateful of these is the linimentum calcis of the Pharmacopœia, applied on the antiseptic cotton, now extensively sold in the shops.

Weak lead lotions are justly popular in the treatment of many of these cases. My colleague, Prof. Haines, suggests, on good chemical grounds, that the acetate of morphia be substituted for the opium in the useful "lead and opium wash." My friend, Prof. R. W. Taylor, of New York, has published an excellent formula for a lotion to be used over raw and discharging surfaces, containing two drachms of the liquor plumbi subacetatis; two ounces of the tincture of opium and one of tincture of camphor; and two ounces of glycerine to a quart of water. This is to be carefully and neatly applied n strips of lint, properly adjusted to the part, and repeatedly wetted. Bear in mind that glycerine is but half a fat, and will prove exceedingly ritating to broken or abraded surfaces, if not largely diluted. When dded to any lotion, it should serve merely to render the specific gravity f the latter equal to that of the exuding serum, lest either exosmosis r endosmosis occur; and neither is desirable.

When a mild astringent effect is desired, or merely the application of ert absorbents to the surface, we have the ordinary black wash, or we n add the subnitrate of bismuth or the oxide of zinc to the other lotions, the strength of one or two drachms to the pint of fluid. Among the medies from the vegetable world may be named the infusion of the ves of the red raspberry (*Rubus strigosus*), which is esteemed chiefly its soothing and anti-pruritic effects.

When the acuteness of the early stages of these disorders is at an end, n, and usually not until then, can we use an ointment with advantage. e simplest and best of these is freshly-prepared cold cream, or even eline, which will do well when the greatly-abused benzoated zinc ointnt has failed. Do not forget, however, that we can add the latter, h great advantage in many cases, in any proportion to either of the mer unguents; and that, for greater stimulating or astringent effects, have a wide range from the excellent diachylon ointment of Hebra as dified by Kaposi, to those containing mercurials and the oil of cade or e oil of white birch.

For the removal of "tan" or "freckles" from the skin of the face, my end, Prof. White, of Boston, employs the following formula, which I ve used with advantage: ℞. Hydrarg. bichloridi. gr. vj; Acid. muriat. ʒj; Aq. ℥iv; Alcoholis, Aq. ros., āā ℥ij; Glycerin, ℥j. Misce. is is applied over night, and the skin washed with soap in the morning. re should be taken to test the susceptibility of the skin before it is too ely employed. When irritating effects are produced, the lotion is to be scontinued.

I conclude by suggesting, in the treatment of herpetic and balanitic orders of the adult male, which are exceedingly common in the summer ason, the use of vinous or alcoholic lotions, sufficiently strong to gently imulate the mucous membrane, and rendered astringent by the addition the sulphate of zinc or tannin. In all cases when practicable, lint satu-ted with the lotion should be interposed in the præputial sac. The "follicular vulvitis" of females is best treated in the same general way.

Gentlemen, you must have ere this perceived the impossibility of ex-austing this interesting subject in the hour at my disposal. It has sufficed merely to enable me to give you a few hints respecting the management of the early stage of some of the disorders I have named to you. Usually, however, long before the subsequent stages are reached, we should fail to recognize them as summer diseases of the skin.

CLINICAL REMARKS ON THE USE OF THE CLAMP AND CA TERY IN THE TREATMENT OF HEMORRHOIDS AND PROLAPSUS.

Delivered at King's College Hospital.

BY HENRY SMITH,
Professor of Surgery in King's College.

GENTLEMEN : You have had opportunities of seeing me operate several ti since the beginning of the present session on cases of hemorrhoids and prola of the rectum by means of the clamp and cautery, and the case just brought fore you is one which so well illustrates this particular operation that I think well to make use of it, as it were, as the text for a few remarks on this subje

The operation consists, as you are well aware, in drawing down and embra the tumour within the blades of the clamp; then removing the hemorrhoid a sharp pair of scissors, and, lastly, applying the actual cautery freely to the surface.

Each of these steps of the operation demands a few words from me. It is important to isolate the tumours well, so as to compress them easily, and in cases where the hemorrhoid runs, as it were, abruptly into the surround hypertrophied skin, it is well just to make a slight groove with a pair of scis By this means the blades of the clamp compress the growth more readily at neck. You will have noticed also that in large tumours I use a clamp furni with a light but powerful screw near its handles. By this means I tighten grasp of the blades of the clamp more firmly; then, in removing the part, I great pains not to divide the base of the tumour too close to the clamp. I tissue to the extent of an eighth of an inch, so as to have a fair surface for use of the cautery. The iron is applied very carefully and very freely at a heat, and then, all the cut surface being so treated, the blades are gently gradually released by the screw on the clamp. In this way the pressure is ta off the neck of the tumour, and if any vessel is not thoroughly cauterized it mediately bleeds. The blades are then quickly screwed up again, and the iron is applied to the vessel until it ceases bleeding. Sometimes it is necess as in a case of huge prolapsus you saw me operate on a little time ago, to reap the hot iron several times to the same vessel before bleeding ceases. You m however, rest assured that with proper care you can stop bleeding from any sel here by the use of the cautery.

Each tumour, and there are generally three or four, is treated in this way, then, when an opiate suppository is introduced by the finger well oiled, the op tion is completed. If there is much hypertrophied skin I remove a portion of and if the sphincter ani is very tight, I divide it, as in fissure of the rectum. do this because I fancy in these cases there is less pain after the action of bowels; for I find that in those cases of long-standing hemorrhoids or prolap when the sphincter is very loose, the patient as a rule complains very little pain after the action of the bowels.

The after-treatment consists in locking up the bowels by occasional opiates, strictly dieting the patient. In the majority of cases the patient complains more or less severe pain for an hour or two, and then it goes off. This pain much alleviated by the application of hot water by means of a sponge. Ret tion of urine sometimes occurs, but not very frequently, more often in wome who generally suffer much more severely from hemorrhoids than do men. As rule, the patient leaves the hospital in a week, the bowels being acted upon b castor oil three clear days after the operation, and then again two days subs quently. Sometimes blood in a coagulated form comes away with the first movement of the bowels, and frightens the patient, but it is only for the most part blood which ran into the bowel at the time of the operation and remained there. At times there may be a little arterial bleeding, but I have never once had to use any stronger measures than to apply a speculum and throw up iced water for stopping any such bleeding.

Now the advantages I claim for this operation are—that it is all completed at once; that it is eminently safe; that the after-suffering is slight, and that the period of convalescence is short. In the old-fashioned method of applying ligaures, the operation may truly be described as not completed at one sitting, for of ecessity the threads are left to come away, not rarely a most tedious and painful rocess. I have seen the most horrible suffering for hours and days after the use f ligatures. Then, again, we may meet with those uncomfortable sequelæ as the sult of the presence of foreign bodies, and the subsequent ulceration, tetanus, ffuse inflammation, and pyæmia. Several cases of death have occurred after e use of the ligature from these and other causes; one or two, I regret to say, my own hands. Some of these cases have been made known, whilst others, pecially those occurring in private, have not been heard of. Now, ever since I gan the clamp and cautery treatment in this hospital, in the year 1864, I am ppy to say we have not had a single fatal or really serious result; and in my n private practice, where during the same period I have operated on several dreds of cases—some of the most severe description, and at all ages up to ty—I have only had one death which could fairly and honestly be placed to account of the operation itself, and this resulted from an accident which ought to have happened, and occurred several years ago. Three other cases, it is e, died after I had performed an operation, but in these instances, all of which e been published, the condition of the patients was such that it would be very air to attribute the fatal result to the operation alone.

was afraid, however, I should at last meet with a fatal result at the hospital, this leads me to call your attention to that case of huge prolapsus in which I rated a few weeks ago. The patient was an elderly man who had a prolapsus big as a cocoa-nut always coming down, and rendering his life a burden. He already been operated upon twice by a hospital surgeon, but in vain. The ient was then sent to me, and, formidable as the case looked, I determined to ertake it. I applied the clamp deeply in three different directions. There a great deal of bleeding, and I had to apply the cautery over and over again ore I could stop it; and then, just as I was finishing the operation, a most toward event occurred—severe vomiting, as the result of the anæsthetic, took ce. The prolapsus was forced still further down; and before I and my assist- s could return the parts, the violent action of the abdominal muscles was such t the weakened coat of the bowel gave way, and a knuckle of small intestine ally protruded through the rent thus made. I carefully returned this as soon the vomiting ceased, and anxiously waited the result. Our house-surgeon, . Newmarch, watched the patient with great care and treated him with great ll, keeping him constantly under the influence of opium, and locking up his wels for several days. The result was not a single bad symptom of any kind. the first action of the bowels there was no protrusion, nor afterwards; and as n as the man was fairly recovered I removed three longitudinal folds of skin m the anus, so as further to tighten the parts. The man was completely cured. ow, the lesson this case teaches is this—not to employ an agent which could e vomiting; because, of course, in such a terribly severe case as this it is olutely needful to clamp deeply, and thus weaken the bowel. It was a most looked-for accident, not likely to occur again; in fact, it is hardly reasonable to expect to meet with another such case for operation. I have, however, been called to cases as bad or worse, but where no operation could be recommended.

Simple and safe as is the operation by the clamp and cautery, it has gone through an ordeal of severe criticism; and although it has for some time bee established as the best proceeding for hemorrhoids and prolapsus, I may refer t the objections advanced against the plan. First, it has been stated that it is rough and painful treatment; but this argument does not hold good now anæsth tics can be used. A more solid objection is, that hemorrhage of a serious nat is liable to occur. I admit this. I am sorry to say I have known of cases wh most serious bleeding has occurred, and I have been informed of two instan where death ensued from this cause; but I maintain that when such accide occur it is in consequence of an error on the part of the surgeon. He either u a faulty clamp or allows a vessel to recede from the blades, so that it does n get touched by the cautery, or he applies the cautery inefficiently. I became little careless after I had operated on a great number of cases, and did not ta sufficient trouble to thoroughly cauterize the vessels, and I had about half-a-do cases of somewhat severe bleeding; but since then—now some five years ago— do not let a single vessel escape without being well cauterized, and I have been troubled by hemorrhage at all. Stricture of the bowel may occur, but t is due to the too free removal of tissue, and especially of the skin about the orifice, and of course may be prevented. As a rule, after very severe operatio I advise the patient to use a bougie for a few weeks; this is a protection agai any possible contraction.

Before concluding, I wish to say a word to you about the history of this op tion. Those of you who have heard my remarks before will remember th have always distinctly disclaimed having introduced this clamp and cautery t ment, and that I invariably give the credit of the origination of the plan to late Mr. Cusack, of Dublin, and you will find this statement in my Letts Lectures;[1] but I have always claimed what merit there may be of improving clamp in such a way that it can be used with the greatest efficacy and saf Hence my name is associated with this means of treatment, and in nearly e important work on surgery the instrument as now used is described and figure mine. I have also in my Lettsomian Lectures, and in various papers, promine drawn the attention of the profession to the subject, and, I believe, have b the means of getting the operation established as it is amongst surgeons both this country and our colonies. I claim no other credit. I should not have m tioned this matter to you to-day were it not for the fact that an attempt has be made in certain quarters to ignore my claim to any little credit which my surgi brethren at large allot to me. The alleged dangers of this operation, too, h been spoken of in such a way as to lead one to suppose that the proceeding is tended with some considerable risk; but I need only repeat to you what I ha told you before, that a fatal result has never happened in this hospital during fifteen years in which the operation has been constantly performed, and und most adverse circumstances, and I have told you of the results of my priv practice; so I must leave it to you to judge how far the operation can be c sidered a dangerous one. In fact, so far as I am concerned, the idea of dang as connected with this proceeding is not associated in my mind when I underta a case of this kind, and so I honestly tell my patients when asked the questio For even in some of those desperately bad cases where the patients have be brought down to the lowest ebb by profuse hemorrhage going on for weeks months, and where some serious result might be anticipated, the safety and su cess of the operation by the clamp and cautery are more marked than in instance of much less severity.—*Lancet*, March 13, 1880.

Hospital Notes.

Cystic Sarcoma of Breast; Extirpation; Neuber's Bone Drainage-tube; Good Result.

A. D., aged 37, single, was admitted into Dr. **Bantock's** ward at Samaritan Hospital, Nov. 26, 1879. She had a cystic tumour of the right breast as large s a turkey's egg, without any glandular enlargement in the axilla. The tumour fected the outer half of the mamma. She had also an abdominal tumour, hich presented all the characters of an uterine fibroid. Its connections were ch as to forbid any surgical interference. The former, however, called for rly operation, as the skin over the most prominent part was becoming very in, and threatened early rupture.

The tumour when first observed, about two years and a half before, was as ge as a pigeon's egg, and was situated near the outer edge of the breast. It s then tender to the touch, but not painful. It had increased most rapidly ring the last six months.

On Dec. 17th the tumour was removed, with the whole mamma, by two ellip-al transverse incisions embracing the nipple. Three arteries were tied with kworm gut, and the ends of the ligatures were cut off short. Compression eeps sufficed for other bleeding points. The wound was closed in its inner f (three inches) by a continuous suture, and in its outer by interrupted sutures silkworm gut. Before the latter were tied a bone drainage-tube nearly three hes long, about a quarter of an inch bore, and about half a line thick, pre-ed according to Neuber's instructions, was inserted. The operation was per-med under phenol spray, but the wound was not washed out. The outer end the tube was trimmed level with the skin, and, instead of the small safety-pin ommended by Neuber, it was secured by means of a piece of silkworm gut ed through it transversely, with ends two inches long. Next the wound, d over the end of the tube, were placed fourfold pledgets of thymol gauze, n alternate layers of thymol and carbolized gauze to the extent of probably enty folds, and they were secured by a many-tailed gauze bandage. Over s a thick pad of salicylic wool was placed, then Lister's eight-fold dressing, d again a many-tailed bandage, with shoulder straps, also of gauze. As much charge was not anticipated, it was thought unnecessary to follow Neuber to e letter in the matter of the dressing.

On the 18th, under the spray, the dressings were removed. There was very tle discharge, and the wound looked as well as possible. The dressings were pplied in the same order, with the exception of omitting the first bandage. enstruation reappeared.

On the 24th the wound was exposed without the spray, and seen to be united roughout. There was not a trace of redness; only the gauze over the tube's outh was soiled. The tube was quite fixed, flattened, and the presenting por-on was dry and otherwise unchanged. The whole of the continuous suture, d two of the others, were removed. Vaginal discharge was very free.

On the 27th, with a view of ascertaining what was becoming of the tube, the ound was again exposed. The gauze was soiled to about the size of a shilling, st going through four folds. Another suture was removed, leaving the one ext the opening. All the white and unchanged portion of the tube was cut way. Beyond this granulation tissue had invaded it. *In fact it had become rganized.* The patient was allowed out of bed, although the uterine discharge ad not ceased.

On the 30th the last suture was removed. No trace of bone could be seen, but a flattened body could be felt occupying the site of the tube, and it was ev dent that instead of melting down and coming away in the discharge it had b come organized in its entirety.

On January 3d there only remained a small granulating surface, less than t diameter of the tube. By the 9th it was quite dry, and the patient left t hospital on the 13th.

Remarks by Dr. Bantock.—In this country attention was first publicly cal to the bone drainage-tube by Mr. MacCormac in an address delivered befor meeting of one of the Metropolitan Counties Branches of the British Medi Association, held at St. Thomas's Hospital on Dec. 3d last. Mr. Krohne already shown me some of these tubes which he had made according to Neub directions, and on Mr. MacCormac's suggestion. I was then waiting for the ti when my patient would be ready for operation, and I made up my mind to the new tube so highly spoken of by Neuber, who is supported by Esmar Neuber cannot be said to have been in a hurry to proclaim his invention, fo was not till he had observed thirty-six cases to their termination that he publis his paper.

The following represents his general conclusions. He says that when a b tube is put into a fresh wound in a good subject, no particular change is obs able within the first twenty-four hours, but soon after that time the outer surf loses its smoothness and presents a worm-eaten appearance, and the thicknes the tube seems to diminish gradually under a slow melting process. In this its solidity is so much impaired that by the fourth or fifth day it collapses un the pressure to which it is subjected. After six or seven days it is reduced pulpy gelatinous mass of more or less cylindrical form, and by the tenth day trace of the tube has disappeared, except the part which is not exposed to action of the tissues, and which is usually to be found loose in the dressings this period. The rapidity of absorption varies in different individuals, dep ing on constitutional conditions and the state of the wound. In one ca amputation of the leg (to which he specially calls attention) in a patient weakened by long illness, and the subject of albuminuria, the tube was absorbed in fifteen days, although the wound had healed almost throughout first intention. In another case of a more vigorous patient, after amputation a large part of the scrotum, no trace of the tube could be found after the te day. He observed that the tube disappeared quicker in cases attended with charge than in those without. He especially claims for his method that fe dressings are required than with the ordinary India-rubber drain, and that it p duces no irritation.

As far as my case goes I think I must admit both these claims. Had it been for my anxiety to see how the tube was behaving, instead of exposing wound on the seventh day, I might have left it undisturbed for a whole fortnig So perfect has the healing process been, that the skin slips freely over the und lying tissues, and the tube moves with it. This indicates the only point of ference—viz., that after a lapse of twenty-six days the tube can still be f apparently of its original size, but flattened. Is it an unmixed gain that it become organized instead of being absorbed or coming away in the discha after having served its purpose? Still, on the whole, the result is very sa factory. The lips of the wound at the end of twenty-four hours appeared to perfectly glued together. Throughout the whole course of the treatment patient felt nothing of her breast wound, and I am inclined to attribute the e vation of temperature on the second and third days, when it ranged betw 99.6° and 100.4°, to the disturbance in the fibroid uterus. One of her us periods had only just ceased a few days before the operation, and the same nig the discharge returned, attended with considerable pain, especially for the fir

our days. All this time, however, the pulse was unaffected. In length
ent this case does not compare favourably with the last case of the same
rhich the tube was removed on the fifth day, and the healing process
complete by the eighth day. But of the two subjects the latter was
the more favourable for operation.

table of cases Dr. Neuber gives three cases of ovariotomy, of which
(of peritonitis), and one recovered. The date of the first dressing in
vas the twelfth day. I do not hesitate to say at once that in this ope-
bone-tube is wholly unsuitable, and that to use it is only to court dis-
this case the principle is entirely different, and the peculiarities of the
are at once seen to defeat the object in view.

ntock adds: Since the above was written I have again used Neuber's
., in a case of irreducible hernia of omentum through the femoral ring,
I unwittingly performed the radical operation for hernia introduced by
Socin of Basle. The case was rather obscure, as at no time while she
my observation had any intestine descended. On the 17th inst. I cut
n the swelling, and at once saw its nature. Completely isolating the
n opened it, broke down an adhesion of the omentum, and tried to
As it resisted reasonable efforts I applied a ligature close to the ring,
way the omental mass. The stump at once receded. I then put a
ound the neck of the sac, and cut it off. Both these ligatures were of
gut, and the ends were cut off short. A small bone-drain was put in,
ound closed by six sutures. On the 19th, the blood, which had escaped
ube, had dried up in the gauze dressing, and the wound was quite dry
t. On the 22d there was only a slight stain on the gauze just over the
uth, and I cut away the end of the tube as close as possible, for this
ressing back the skin, so that the edge of the skin overlapped the tube.
4th the skin had come together and united, and the healing was thus
On this day I removed the sutures. In this case also the tube was
ly fixed at the first dressing, and its organization was even then assured.
o be felt under the skin. There is reason to hope that this operation
a radical cure, as the ring was not stretched, and the ligatured neck
a firm and resisting plug.—*Lancet*, May 1, 1880.

Gangrene of the Lung; Recovery.

n M——, aged twenty-seven, a barman, was admitted into Dr. STUR-
rd at the Westminster Hospital, 7th October, 1879. He had rheumatic
n a child, but no other illness previous to the one complained of. Five
ore admission he had been much exposed, and caught cold, complaining
pain in the left side of the chest, profuse expectoration, and dyspnœa.
nptoms became more marked, and the patient also complained that his
d sputa were very offensive, and that the dyspnœa frequently came on
paroxysms.

s very anæmic in appearance, and seemed very weak, having lost flesh
bly. His breath and sputa were of the characteristic odour of pulmonary
; the fetor was so intolerable as to make it most difficult to approach
was noticeable throughout the ward. The sputa were frothy at the
ut had a blackish-gray layer below, the sputa having the same odour as
h. On percussion, there was a patch of dulness over the left base behind,
ree inches square, and on auscultating over this patch crepitation of
character was heard during inspiration and expiration. The other parts
ngs gave evidence of bronchitis.

urges diagnosed the case as gangrene of the lung, and ordered the patient to be placed in a complete atmosphere of carbolic acid vapour. A tent was placed round the bed head, and vapour of carbolic acid was passed into the tent. Th strength of the solution was one per cent. One drachm to half a pint of wat was used for vapourizing, and then gradually strengthened.

The patient was kept in this atmosphere for five weeks; for the first fourte days the symptoms of cough and dyspnœa were no better, but the offensive odo of the expectoration disappeared; sputa still giving evidence of pulmonary brea down. During the remaining three weeks of this treatment the symptoms grad ally improved, and the patient became better and stronger, and increased i weight.

On November 12th he was examined, and it was found that the physical sig at the left base had much improved, the breathing being fairly healthy. T sputa were no longer black and offensive.

On the 20th the patient was discharged in fair health.

There was nothing to remark about the temperature; the diet was mainly mi beef-tea, and light puddings; meat during convalescence. The carbolized vap had evidently prevented the gangrene from spreading after the slough had b thrown off in the sputa; the lung gradually regained its normal character. *Lancet*, April 10, 1880.

Whooping-Cough in a Man of Sixty-six treated with Drosera Rotundifoli

William H——, aged sixty-six, beadle, came under Dr. **Murrell's** car the Royal Hospital for Diseases of the Chest, in January, 1879, suffering f whooping-cough. He stated that he had had it for about three months. attacks of coughing ended up with a distinct whoop and a violent struggle breath. He had usually six or seven bad attacks in the day. They were accompanied by vomiting, but terminated in the expectoration of thick phlegm. The cough was most violent, and exhausted him very much, an was glad to lie down after each paroxysm. There had been no hæmoptysis, shortness of breath, and no night-sweating. He had lost flesh a little, but thi attributed to his loss of appetite. He was hoarse, and could not lead the sin as usual. His chest was carefully examined, but nothing wrong was detec There was no doubt about the nature of the complaint, and one Sunday morn he whooped in church, to the consternation of the congregation He had b exposed to whooping-cough, more or less, all his life, and thought he had cau it from some of the school children. This was his second attack, for he had it as a child. He mentioned incidentally that his wife had it when she was si

He was ordered fifteen grains of bromide of potassium in an ounce of w three times a day, and this he took for a fortnight with only slight benefit. was then ordered a one-in-ten tincture of drosera rotundifolia (*The Lan* August 3, 1878), in five-drop doses, every four hours, in a little water. He t this for a week, and then returned, saying that it had made him much worse. increased the spasm and cough, and made him whoop more; he whooped as m as a dozen times in a single paroxysm of cough. It increased the expectora too, and he begged that he might be allowed to discontinue the medicine. was then ordered half-drop doses of the same tincture in half an ounce of w every three hours. At the expiration of a week he reported that there had b a very great improvement; the cough was less, and he rarely had more than attack in the twenty-four hours. He slept better, and his appetite had improv He took the medicine for a fortnight longer, when the cough had completely him. He was quite well, and was able to sing bass and lead the choir once mor

The points of interest in the case are—the age of the patient, and the fact of th drosera having succeeded in small doses after having failed in large.—*Lance* April 17, 1880.

MONTHLY ABSTRACT.

Anatomy and Physiology.

Growth of the Human Hair.

ference to the amount of hair produced on the head and beard in rela- me, Professor Moleschott (*Untersuch. zur Naturlehre*, Band 12, p. found by frequent cutting of the hair in an observation extending over eleven persons, a maximum production of 0.28, a minimum of 0.14 ; the average being 0.20 gramme daily. The watery contents of the nt on an average to 13.14 per cent.; the loss of nitrogen in this way o 0.0287 gramme = 0.0615 gramme of urea. 2. As regards the growth r in relation to age and to the weight of the individual, the daily growth 8 and 26 years of age is, on the average, 0.20 gramme; between 32 ars of age, on the contrary, only 0.14. The smaller production of hair ed with the larger body-weight, but the greater body-weight was always ciated with an older age. 3. Concerning the influence of the time of as ascertained that the production of hair is stronger in the summer than ter. The hair has, indeed, in summer, a larger amount of water; but ins the considerable difference only in very small part. 4. Concerning nce of the frequency of hair-cutting on the growth of the hair, Mole- ertained that the ordinary notion that frequent cutting increases the n is correct. 5. Concerning the growth of the nails, in the course of a uthor produced on his hands 1.825 grammes, that is, 0.267 gramme of or 0.572 of urea; in another year, 2.086 grammes of nail-substance, nitrogen. The growth of the nails is more rapid in summer. 6. As e reproduction of the skin, after a boil on the volar side of the fingers, tt lost a piece of epidermis which measured 75 square millimetres; it millimetre in thickness, and weighed 0.0227 gramme. The loss was vered in 34 days. The surface of the body measures on an average are metres. If it be assumed that the epidermis of the whole surface dy is renewed to the thickness of 0.125 millimetre in 34 days, there is a of 14.35 grammes of epidermic substance through the unobserved des- n. This quantity corresponds to 2.1 grammes of nitrogen, or 4.5 of urea. Salkowski, who abstracts this communication in the *Berl. latt für die Medicin Wissensch.*, observes that the whole calculation of the renewal observed as a sequel of a pathological process after epi- ad been removed, and gives, doubtless, too high a figure. 7. As re- influence of disease on the renewal of the epithelial tissues; Moleschott three weeks from catarrh of the bladder; during that time the produc- air and nails was diminished. 8. In his conclusion, Moleschott points that, by the elimination of the epidermic tissues, one-seventh of the of nitrogen which is found in the urine is daily eliminated.—*London Med.* April 15, 1880.

Materia Medica and Therapeutics.

Acetate of Alumina as an Antiseptic.

The expense and the want of durability of Lister's carbolic gauze have led to several attempts to replace the carbolic acid by other antiseptics. Of these, acetate of alumina, which was used as early as 1827 by Gannal for embalming corpses, and which has of late been introduced into surgery by Burow, von Bruns, Billroth, and Maas of Freiburg, appears to deserve special attention. It has been largely tried in Professor Maas's wards since June, 1879, and his assistant, Dr. PINNER, gives an account of its physical properties, and of the method employed and results obtained in its surgical application at Freiburg, in Nos. 12 and 13 of the *Berliner Klin. Wochenschrift*, 1880, from which the following facts are abstracted.

The solution of acetate of alumina (for the salt is not stable in the solid form) is made by dissolving 1000 parts "colloidal alumina," prepared by the firm of Löwig & Co., Dresden, in 800 parts dilute acetic acid. The liquid is filtered after standing twenty-four hours, and contains about 15 per cent. of acetate. For antiseptic purposes much weaker solutions are required. Dr. Pinner finds that a 0.5 per cent. strength will prevent urine or meat infusion from putrefying, while 1.5 to 2 per cent. solutions will stop all movement in a bacterial liquid, as well as sterilize the bacteria, so that no multiplication of them takes place in tubes containing Pasteur's fluid, and carefully isolated. Dr. Pinner does not wish, however, to assert that the bacteria are actually *killed;* to effect this, much larger quantities of this or any other antiseptic than it is possible to use in practice are probably required, as well as exposure to high temperatures. His view of surgical antiseptics is "to create such conditions in the wound as to render the fungi innocuous, unable to cause injurious decomposition, or to penetrate the surface of the wound and enter the blood."

The method of operating with acetate of alumina as an antiseptic, in accordance with these principles, is as follows: The skin is first washed with 5 per cent. carbolic acid solution in the ordinary way, and dried. The reason for this is that acetate of alumina is not saponifiable. Carbolic acid has also been used for disinfecting the instruments, as the acetate solution is so acid that it blunts and corrodes them. For every other part of the operation the acetate of 2½ per cent. strength is alone used. Owing to the admixture of steam the actual strength of the spray which reaches the wound does not exceed 1 to 1½ per cent.; but this answers all purposes. The acetate spray never causes anæsthesia of the operator's hands, as carbolic acid is liable to do, but it makes them rather rough. Professor Maas uses catgut for ordinary ligatures, and Czerny's antiseptic silk for atheromatous vessels or for deep-seated or large arteries. The sutures and drainage-tubes are inserted in the ordinary way. For the dressing, the wound is first covered with "protective," and then with loosely folded pieces of gauze, which are pressed firmly over and around it. The gauze has previously been soaked for a long time in 5 per cent. acetate of alumina solution, and wet compresses of the same, one and a half to two metres long and about twenty centimetres broad, four times folded, are used to keep the dressing in its place. From four to eight such compresses are generally needed, the rule being, *e. g.*, for an excision of the knee, to carry the dressing from the lower third of the leg to the upper third of the thigh. The whole is covered with gutta-percha tissue to prevent evaporation, the edges being surrounded with strips of 10 per cent. salicylated wool. To keep everything in place a calico bandage soaked in 2½ per cent. solution of the acetate is used. The dressing is changed on the first or second day after the operation, only every fourth or sixth day; it has never been allowed to remain an the eighth day. On removal the compresses are found impregnated secretion from the wound, which has a sourish smell, and is rather more han when dry bandages are used, the moist compresses being more per- on the other hand, wounds and the surfaces of stumps have a cleaner he healing of the wound takes an absolutely aseptic course. None of the which complicate wounds under the old system (*accidentelle Wundkrank-* ccurred in any of Professor Maas's cases. In three cases it was noticed acetate of alumina spray exercised an astringent effect, and checked the hemorrhage from the part which has been operated on. In this respect rior to carbolic acid.

etate of alumina bandage is cheaper than Lister carbolic gauze. The alumina is sold by Löwig & Co. at forty-five shillings the hundred mes, and dilute acetic acid is also cheap. The compresses can be used over again after boiling and re-washing, and they are easily prepared. apt themselves well to any part of the body, and can be made to exert elastic pressure on the wound. Eczema never occurs beneath them. er gives details in his paper of a number of severe operations treated by e method with success. The acetate has also been used by Professor permanent irrigations. Professor von Bruns, of Tübingen, first recom- it for this purpose—"severe injuries, especially compound fractures me rather late under treatment, cases of extensive sloughing or great on of soft parts, or, in fact, any cases where it is difficult to apply an dressing successfully, can be thus treated." It is best to begin with a nt. solution, and then to reduce its strength to 0.5 per cent., which is be strong enough to disinfect and deodorize perfectly.—*Med. Times and* May 8, 1880.

Medicine.

Growing-Pains.

UILLY, in an article published in the *Revue Mensuelle de Médecine et rgie* and the *Journal de Médecine et de Chirurgie Pratiques*, Decem- , studies, under the appellation of "The Fever of Growth," the attacks tion which occur in the bony tissue of the extremities of long bones, and ay go on to inflammation and coincide with febrile conditions connected th some other distant lesion. The phenomena are of various kinds. In rable number of cases, on the appearance of any insignificant affection, slight angina or a feverish gastric disturbance, there supervenes in chil- ery high fever, lasting, at the most, from twenty-four to thirty-six hours, ifestly connected with the local lesion. In addition, however, the patient pression quite out of proportion with the slight malady from which he is ; during the febrile attacks, and for the two or three subsequent days, especially on pressure, a very decided sensibility over the epiphyses of r, tibia, and humerus; and, if care be taken to measure the child before- ter the attack he will be found to have grown four or six-tenths of an inch. other form, the fever seems to constitute the whole disease. On this I. Bouilly cites two cases observed by himself, in which the symptoms l in a series of paroxysms of intermittent fever, having in one case a ter- l in another a quotidian type, commencing with a morning rigor, followed and terminating early in the night by copious perspiration. At the same time, pressure revealed the presence of decided pain at the level of the great epiphyses, especially at the moment of the attacks, less marked during the intervals. In each of the children, one of whom was thirteen and the other seven years of age, the increase in growth in a week was an inch. The attacks yielded to sulphate of quinine and perfect rest, but convalescence was complicated with a condition of languor and depression, and was much more protracted than might hav been expected after a week's illness in children of good constitution. Here w find a type of the fever of growth, probably connected with congestion of th epiphyses.

Analogous facts have been pointed out by other medical writers. M. Bouchu has reported the case of a child, twenty-five months old, who grew more th three inches in six weeks, being affected with remittent fever, which the auth believed to be connected with this growth. Regnier has also recorded the ca of a youth aged 14, who was excessively short for his age, and was seized wi extremely acute pains pervading all the joints. In six months he grew more th twenty inches. The absence of fever prohibits the supposition that the case w one of acute articular rheumatism. It is very probable that the patient had a seri of attacks of juxta-epiphysary osteitis, which gave rise in six months to this eno mous increase of growth. M. Bouilly, also, in pointing out that these fevers growth are caused by congestive outbreaks in the vicinity of the joints in the ep physary zone, considers them as the mildest stage of osteomyelitis of children a adolescents.—*British Med. Journal*, May 15, 1880.

Salicylic Acid in Acute Rheumatism.

Dr. Von Bokkenheuser contributes to the last number of the *Nordiskt* *dicinskt Arkiv* an interesting paper on the treatment of acute rheumatism salicylic acid. The following are his conclusions:—

1. Salicylic acid is a specific against acute, febrile, articular rheumatism.
2. Its essential properties consist in the power it possesses of causing the aff tions of the joints to disappear and the fever to yield within some few days.
3. This result is effected with equal facility in patients of different sexes a ages; at the same time the effect is the more speedy and complete the earlier the disease the patients come under treatment.
4. Salicylic acid is not capable in any special degree of cutting short the d case; but it alters its character in such a way that the patients, after the lapse the first few days, do so well that they no longer feel themselves ill.
5. The treatment with salicylic acid does not always prevent a relapse, even an "after-cure" is employed; but as a rule such a relapse can be brought to yie again in a very short time.
6. It is possible, and even probable, that the treatment with salicylic acid often capable of preventing the outbreak of acute affections of the heart and lung and it is certain that these, when they do arise, pass off in a milder way th they otherwise usually do. In particular, it may be laid down that this treatme almost excludes the occurrence of an attack of pleuritis.
7. Salicylic acid is capable of stopping, in the course of a few days, an acu exacerbation of a chronic articular rheumatism.
8. Against monarticular pains salicylic acid is ineffective.
9. It likewise appears to be ineffective against attacks of a febrile acute artic lar rheumatism, even when these are of a polyarticular and wandering nature.
10. Against rheumatic hyperpyrexia salicylic acid has no effect.
11. In the case of a very few patients there seems to be such an immunity against salicylic acid that it produces no effect upon them.

2. The treatment with salicylic acid does not exclude all other methods of tment, such, for example, as the use of baths, protective bandages, and the

. No definite contraindication to the use of salicylic acid seems to exist; but times circumstances may require us to discontinue the medicine either for a or altogether.—*Med. Times and Gazette*, June 5, 1880.

The Spirilli of Relapsing Fever.

. **Paul Guttmann** (*Verhandlungen der Physiol. Gesellschaft zu Berlin*, 7, 1880) has examined the blood of more than two hundred relapsing-fever nts treated in the Berlin Barrack Hospital, and has never succeeded in ting the characteristic spirilli of Obermaier except during the pyretic period. e case he found spirilli motionless in the blood of a corpse thirty-six hours death; in another they were still alive thirty-six hours after the patient's . What becomes of the spirilli in the intervals between the relapses is still tery. Dr. Guttmann rejects Arndt's supposition that these bodies are not ites, but processes emitted from the red blood-corpuscles owing to the high At present, however, all his attempts to cultivate the spirilli outside the n body have failed. The blood of relapsing-fever patients also contains a er of very minute moving corpuscles, which are rather more numerous the febrile periods than in the interval. They are not, however, peculiar apsing fever, but occur in many other acute diseases, and, more sparingly, n healthy human blood. They can be cultivated in Pasteur's fluid, and r to be certainly micro-organisms derived from the atmosphere.—*Med. and Gazette*, May 8, 1880.

peutic Value of Salicylate of Sodium in the Intermittent Fever of Children.

J. **Zielewicz**, in the *Deutsche Med. Wochenschrift*, No. 41, 1879, re- 207 cases of intermittent fever treated successfully with large doses of sali- of sodium given during the febrile period. As regards certainty and rapid- action, however, it is inferior to quinine. To children under one year an e amount of 3.5 grammes (with a range of 3 to 8 grammes) was adminis- ; to children of 1 to 4 years, 5 to 6 grammes were given; and to children years, 8 to 10 grammes. The treatment is less expensive than that by qui- —*London Med. Record*, May 15, 1880.

Tuberculosis as a Contagious Disease.

re are few names known to contemporary medical science which arrest the ion of students of pathology more powerfully than that of Professor **Cohn-** of Leipzig. In the early part of his career, he distinguished himself by es of remarkable discoveries, and he is now becoming widely known and ciated as a lucid and suggestive teacher. In none of his published writings which we are acquainted is this power of exposition more happily developed in a small *brochure* from his pen on tuberculosis viewed as a contagious ly,[1] which has been recently published. A short account of the method by the author attempts to harmonize the varied observations which have been tly made on this disease, by showing how they are all explained by the as- tion of the truth of one central fact, for the appreciation of which medicine umanity are indebted to the science of experimental pathology, will prove useful, if it do no more than show how much is being done, and yet remains to be done, in a fruitful and important field of research.

---

[1] ie Tuberkulose vom Standpunkte der Infectionslehre; von Julius Cohnheim. ig: 1880.

In the theory which was originated by Virchow, long adopted in Germany, and now largely taught in this country, it is held that a fundamental difference exists between miliary tubercle—tubercle properly so-called—and the inflammatory products found in scrofulous disease of the lymphatic glands, and in the form of phthisis called by the Germans caseous pneumonia. The latter processes are regarded by Virchow as purely inflammatory in their nature, and as differing from other inflammatory processes only in that there is neither absorption nor further development. This theory is based on certain anatomical facts, and may be conveniently termed the anatomical theory. One of the objects of Professor Coh heim's *brochure* is to show that, since Villemin has proved that tubercle can be transmitted by inoculation, this anatomical theory has been completely shattered. The test for tubercle now no longer consists in certain qualities of colour or co sistence, nor in the presence of certain microscopical elements—tests which, i any case, have been shown, during the last few years, not to have the value whi had been assigned to them—but in the capacity of a morbid product, when i troduced into the body of a rabbit or a Guinea-pig, to produce tuberculosis in t animal. What produces tuberculosis is tubercle, what fails to produce tuberc losis is no tubercle. Judged by this criterion, the caseous pneumonia and mili tubercle are manifestations of one virus; and the doctrine of Laennec, which a time had been in the shade, has now received ample confirmation. Furth the scrofulous lymphatic gland is found to contain the same poison.

For the application of this test all animals are not equally reliable. "Do for example, show little susceptibility, whilst rabbits and Guinea-pigs have it a remarkable degree. The way in which the tuberculous substance is introd into the animal is almost a matter of indifference; the common and most co nient method of procedure is inoculation by a small incision either into the cutaneous tissue, the pleural or peritoneal cavities, or the anterior chamber of eye. Chauveau and others have infected rabbits by feeding them with tuberc matter, and in Munich animals were rendered tubercular by inhalation of tub cular sputa in spray. Whether there is much or little tubercular substance e ployed, whether it is used alone or mixed with other tissues—as, for examp pieces of lung containing tubercular nodules—is of little importance; of greater consequence, on the other hand, is it that the substance used should fresh and free from decomposition. The fresher it is, the less likely is the ex riment to be affected by septic and similar influences, and infection is the m certain. How the infection takes place, is best seen in animals when the tub cular matter has been introduced into the anterior chamber of the eye. In t case, if the substance be absolutely fresh, the irritation produced by the int duction soon passes away, the small portion introduced becomes gradually smal and smaller, and may even completely disappear. Then, for a time, the eye completely clear and intact, until suddenly on the iris a smaller or larger numb of minute gray nodules appear, which grow to a certain size, and then case exactly as happens with human tubercle. In the rabbit, Salomonsen and Co heim observed the eruption usually about the twenty-first day after inoculati in Guinea-pigs, as a rule, a week earlier. In the rabbit, also, the period of i cubation is sometimes shortened to fourteen days."

It is this test that, applied to human tubercle on the one hand, or caseati scrofulous products on the other, shows that they are both caused by the sa virus. All these morbid products are effective, and in the same degree. If piece of tubercular peritoneum or cerebral membrane be introduced into the pe toneal cavity of a rabbit, typical tuberculosis, beginning in the abdominal orga

e result. But inoculation with a piece of lung affected with caseating pneu-
ia, or of a caseating testicle, produces exactly the same effect, and nothing
eeds better than a freshly excised scrofulous lymphatic gland from the neck.
hose who are convinced that all contagious virus is due to a parasite will, of
se, not hesitate to believe that the tubercular poison is corpuscular, and that,
not very distant future, this corpuscle will be demonstrated in the tubercle-
le and in scrofulous products. Until, however, this goal has been reached,
remains no other test for tubercle than that of infection. The leading
ciple here, as in all infecting maladies which produce local changes, is that a
rcular or scrofulous product is generated wherever the tubercular virus is
ent and remains for a certain time. The chief factor, therefore, in deter-
ng the localization of the disease, is the mode of introduction into the sys-
Once introduced, its further extension is influenced by the conditions of
structure of the part, and takes the direction of the natural roads of the
nism. Consequently, whilst, on the one hand, the course which the disease
is very different in different cases, the eventual entrance of the virus into
circulation affords the conditions for the development of tubercle in distant
ns. The influence of the point of introduction is strikingly exemplified by
lation experiments. When a small piece of tubercle is introduced into the
oneal cavity, there constantly follows, in the first instance, tuberculosis of the
oneum, spleen, and liver; after inoculation into the anterior chamber of the
the iris is first affected; after feeding with tubercular matter, the intestine
he mesenteric glands; after the inhalation of pulverized sputa, the lungs and
chial glands; and, when the material has been introduced into the subcuta-
s connective tissue, it is the nearest lymphatic glands in which the disease
develops.

hat the lungs are affected with tubercular disease in a far larger ratio than
r organs shows, in Professor Cohnheim's opinion, that the poison is intro-
d into the human economy most frequently with the inspired air. This con-
ion finds support, he believes, in the frequency with which the bronchial and
eal lymphatic glands are affected in a very early stage of the disease—so
h so, that an extensive tubercular pleurisy, and still more frequently advanced
ation of the glands, is found, whilst in the lungs there are only found a few
les or a very scant amount of caseous infiltration. An analogous condition
und in the certainty and rapidity with which inhaled carbonaceous particles
h the pleura and bronchial glands. The conditions which determine whether
inhaled virus shall produce disseminated tubercle or caseous pneumonia are
unknown.

hilst the pleura and bronchial glands become diseased immediately after or
ltaneously with the lungs, the anatomical relations of the air-passages with
other and the digestive canal furnish the means for further development of
disease. So soon as a breaking down of tubercular products and consequent
ration have taken place, a certain quantity of tubercular, that is to say, of
cting matter, must leave the lungs. This reaches the trachea and larynx,
if it take root there, tubercle and tubercular ulceration are the consequence.
n come the pharynx, the soft palate, the root of the tongue, and tonsillar
on, which are all exposed to the same influence. A certain proportion of the
ter is swallowed, but the passage through the œsophagus is too rapid, and un-
btedly the acid reaction of the gastric juice too adverse to the local inocula-
and further development of the organized tubercle-poison, to favour the
elopment of the disease in the gullet and stomach, where tuberculosis is ex-
dingly rare. When, in consequence of the swallowing of large quantities of
ercular matter, catarrh of the stomach has been produced, the chief obstacle

to the transmission of the virus into the intestine is overcome. In the bowel infection will most likely follow at points where the intestinal contents are longest detained; that is to say, in the neighbourhood of the ileo-cæcal valve, the lower portion of the ileum, the cæcum, and ascending colon. The upper and lower extremities of the tube are less exposed. It is easily ascertainable in what parts of the intestinal wall the tubercle is most likely to fix itself—on those points, namely, where all absorbed substances are first retained; that is to say, in the lymphatic structures, the isolated and grouped lymph-follicles. These are, in fact, as is well known, the seat of caseating and tubercular ulcers of the intestine. Simultaneously with or immediately following the development of the virus in the follicles comes the devolopment in the mesenteric glands; whilst, on the other hand, the tubercular ulcers admit the poison into the branches of the portal vein, and the liver is then endangered. How frequent is tuberculosis of the liver, every one knows who has taken the trouble to examine this organ with sufficien care in all cases of chronic tuberculosis. With this combination, consumptive disease of the lungs and intestine frequently ends, but further developments some times take place. The disease may enter the ductus choledochus and produc tuberculosis of the bile-ducts. More frequent and more important is transmissio to the peritoneum from deep ulcers of the intestine. And the virus inhaled wit the atmospheric air may take root directly in the larynx and trachea, producin the so-called primary tuberculosis of the larynx.

Whilst the tubercular disease of the digestive tube which has been describ in the foregoing sketch is secondary to the affection of the lungs, there are cas in which the intestinal canal admits the virus into the system for the first tim Amongst this class of cases, Professor Cohnheim reckons advanced tubercul disease of the mesenteric glands and peritoneum, without disease, or with only very slight disease of the lungs—a form of the affection rare in adults, but fortunately very common in young children. The reason why young child are specially exposed to this danger may, perhaps, be found in the experime of Gerlach, Klebs, Orth, and others, who have shown how close is the connecti between the virus of the consumptive disease of cattle and that of human tube culosis, and have further proved that the virus from the diseased cows is contain in their milk. Whether the milk of tubercular women contains the virus do not seem yet to have been investigated; but, with the well-known prevalence tuberculosis amongst cattle on the one hand, and with the widespread prevalenc of the habit of bringing up children on cow's milk on the other, an explanatio of the frequency of primary consumptive disease of the intestines is ready to hand. Perhaps the influence of food in producing tubercular disease has even wider extent. The question may at least be entertained whether all the so-called scrofulous inflammations of the lips, mouth, and pharynx, and especially th caseating swellings of the lymphatic glands of the neck, are not due to the direc inoculation of the tubercular virus contained in food, and more especially here, also, in infected milk.

Professor Cohnheim's remarks on uro-genital tuberculosis are very suggestive. Direct infection from one sex to the other, as by syphilis, although not impossible, is scarcely to be expected. If the virus from tuberculosis of the uterus ever is transmitted *in coitu* to the male urethra, or, perhaps, what is not so unlikely, if a man with tuberculosis of the lungs or other organ can transmit the tubercular virus to the genital mucous membrane of a woman, such cases must still be very exceptional. As a rule, uro-genital tuberculosis is a disease of excretion. The virus, from whatever source it has entered the blood, is excreted by the kidneys, and doubtless, like cinnabar particles, oil-drops, milk-globules, and bacteria, through the glomeruli. It by this means gets access to the urinary passages, and, hatever point it gets a hold, tuberculosis develops. Most frequently, this s place in the open canaliculi of the pyramids; but the disease may develop in the pelvis of the kidney, in the ureter, and the bladder, and even in the tatic portion of the urethra tuberculosis may occur. It may cross in the der to the other ureter, and ascend to the other kidney; more frequently, ever, it is the urethra that is attacked. In the male, the virus attacks the tate, thence passes by the *ductus ejaculatorii* to the seminal vesicles, and rds to the vas deferens, the epididymis, and testicle, but it can also pass tly where the ureter and the vas deferens cross. In the female, the anacal arrangements of parts renders the route by the urinary passages very imable. In the great majority of cases, the parts affected are the Fallopian and the uterine mucous membrane, the virus entering the tube from the oneum, which is scarcely ever found free from tubercle in genital tubercuin the female.

though analysis shows that uro-genital tuberculosis is scarcely ever the primary eak, this cannot be said of all the parts where tubercle is localized. In ngeal tuberculosis, there are cases, especially in children, in which the usual its in the lungs or glands are not to be found. How, in such cases, and in those in which the deposits in other organs are present, is the transmission e virus to the meninges of the brain to be explained? Dr. Cohnheim is in instances disposed to accept Weigert's explanation, who has suggested that oison gets access to the membrane of the brain from the nose, passing through oramina of the ethmoid bone.

ll more difficult of explanation are cases of tubercular disease of bone and ting tubercular disease of joints, occurring in individuals in whose other s no tubercular deposit is to be discovered. Although in most such cases evelopment of the local disease is traced to an injury, yet it is not to be supl that an injury can beget the tubercular poison. Professor Cohnheim cons it to be possible that, in such persons, the virus is already circulating in the l, and that, with the exudation which follows the injury, the poison leaves loodvessels and engrafts itself in the tissues.

a rule, the tubercular poison is not spread through the medium of the circion, although in favourable instances this occurs; and metastatic tubercle, arable to the most developed forms of metastatic inflammations and tumours, metimes found. When we add to this mode of infection the direct transon from the peritoneum to the spleen, through the lymphatics of the diagm to the pleura, from the pleura to the pericardium, etc., we need not wont the number of organs that are sometimes found affected with tuberculosis. explanation of instances of acute miliary tuberculosis come the cases deed by Ponfick, in which, as a cause of the contamination of the blood with quantities of the poison, tuberculosis and caseous infiltration of the thoracic were found. A more frequent cause, however, of this rapid form of the se is tuberculosis of the bloodvessels of the lungs, instances of which are ded by Weigert. A local tuberculosis of the pleura, bronchial glands, or iastinum has extended into the wall of a pulmonary vein, and a large surface seating tubercular substance has projected into the lumen of the vessel. In ight of these discoveries, acute miliary tuberculosis loses much of its mystery. hen the chronic nature of scrofulous affection of the lymphatic glands, and immunity to the general health that often follows it and scrofulous disease of joints, are compared with the rapid and deadly course of acute tuberculosis, ay seem extraordinary that they are all attributable to the same poison; but ulation of rabbits shows that they all produce the same disease—a pure tubersis. In endeavouring to account for the comparative innocence of some classes of cases, it must not be forgotten that the human organism may even overcome entirely the poison. Tuberculosis can heal. Pathological anatomy has long known cretification and cicatrization after tubercular deposit and ulceration. Profes Cohnheim, assuming the error of the dualistic theory of syphilis, compares th localization of tubercular affections with cases of syphilitic infection in whi there is no manifestation of disease further than the nearest lymphatic gland Individual differences in the behaviour of the organism which has been infected by tubercle are seen even in inoculated rabbits. When equally large pieces of th same caseating lymphatic gland are introduced into the peritoneal cavity or int the anterior chamber of the eye of a number of Guinea-pigs or rabbits, the fir outbreak of tuberculosis takes place at about the same time and in the same ma ner in all of them, but the further progress shows the greatest imaginable diver sities. One animal succumbs after five weeks, and, on examining the body nodules and caseation are found in almost every organ: the peritoneum, liv spleen, lymphatic glands, the lungs, vascular walls, etc. A second lives over tw months; a third, three months, and longer; in another, not only the eye but th lungs are almost completely filled with tubercle; in another, the respirato organs are almost entirely free, whilst the abdominal organs are extensive affected; in a sixth, the eye is completely destroyed by caseous panophthalmit whilst the animal is otherwise perfectly healthy, is not emaciated, eats well, a is strong and lively; and when finally, after many months, it is killed, tuber is found nowhere except in the eye.

Professor Cohnheim will not have it that the different powers possessed by i dividuals of resisting the tubercle poison are due to the presence or absence of phthisical or consumptive habit of body. The so-called consumptive habit body has nothing to do, he believes, with a facility for receiving the virus, b a product of the disease. Individuals with this phthisical habit of body are specially predisposed to tubercle, they are already tubercular. In their case, disease has been either acquired in early life or has been inherited. That tu culosis is hereditary is too well known to require to be more than stated; b translated into other language, that means nothing more or less than that tubercle-virus can be transmitted in the semen and in the ovum: whether can, like the virus of smallpox, be transmitted to the fœtus through the placen circulation, remains yet to be learned. The only difference in this respect b tween it and the syphilitic poison is that, while the latter manifests itself in th offspring before or soon after birth, in the case of the tubercle poison the deve opment takes place at a later period.

Thus, in the whole history of tubercle everything is due to the special natu of the poison and its effects. According to the present manner of looking at th subject, every man is tubercular in whose body the tubercular virus has tak root. There is, accordingly, no predisposition for tubercle any more than the is a predisposition for syphilis, although some persons are more easily infecte than others. Nor is there any constitutional predisposition that causes hype plastic or inflammatory products to caseate like tubercle instead of being absorbe or changed into connective tissue, but only those pathological products underg the specific change which are already the product of the tubercular virus. Othe than this, there is nothing in the whole course of tuberculosis wherein there is difference in principle between it and other diseases arising from local infection. Not even the fever is pathognomonic.

The summary which we have given of Professor Cohnheim's views, and as far as possible almost literally in his own words, will, we hope, give some idea of the nature of one of the problems that have been for the last few years earnestly engaging the attention of pathologists, and will also indicate the line of observa-

and investigation that inquirers are now following in endeavouring to acquire
er knowledge of the nature of tubercular disease. The small *brochure* on
n we have so freely drawn, well merits the attention of all who are engaged
e active practice of medicine; and as this is hardly possible so long as it is
accessible in the original German, we would fain hope that some competent
nay translate it in its entirety.—*British Medical Journal*, May 8, 1880.

Note on a Case of a Severe Attack analogous to Gastric Vertigo.

an interesting communication on this subject, Dr. JAMES RUSSELL, of the
ngham General Hospital, makes the following instructive remarks:—

ere are few forms of disease in which clinical phenomena illustrate in a
interesting manner the results afforded by the minute dissection of the
s, characteristic of the anatomy of the present day, and the relations held to
nother by certain nerves in their ultimate distribution, than that large and
s group of cases which have vertigo for a leading symptom. The explana-
f the phenomena presented by Menière's disease, which is based upon the
nce exerted on the semicircular canals in directing the equilibrium of the
is in striking agreement with the observations made by the late lamented
art Clarke, in his laborious dissection of the medulla oblongata, reported
Philosophical Transactions for 1868. It is there explained that the outer
nner auditory nuclei are derived mainly from the gray matter of the resti-
body and of the posterior pyramid (the restiform and post-pyramidal
); and, further, that one division of the root of the auditory nerve (the
or division) may be traced to the superior vermiform process of the cere-
n.

h this demonstration by Dr. Clarke, of the connection between the central
s of hearing and the cerebellum, may be connected the suggestions of Dr.
lings Jackson as to the office held by the cerebellum in directing the auto-
movements of the muscles and limbs, and especially in maintaining the
orium of the body, which are epitomized in the *Medical Times and Gazette*,
er 26, 1878. But the group of cases to which this explanation applies has
argely extended by Dr. Woakes, who has brought the well-known cases of
ch vertigo within the same category, although in these cases the auditory
atus, central and peripheral, is itself quite free from disease. Altered cir-
on within the labyrinth, and consequent compression of the endolymph,
tute the basis of Dr. Woakes's explanation; and he refers, in confirmation,
relations which are effected in the inferior cervical ganglion, between cer-
fferent nerves from the stomach and the vaso-motor branches of the sympa-
present in the vertebral plexus. (*Am. Journ. Med. Sci.*, N. S., vol. lxxv.,
page 419.) But the nervous connections which subsist in the inferior cer-
ganglion are shown by Dr. Woakes to comprise, in addition, the inhibitory
of the heart, besides the vaso-motor plexus of the vessels of the arm: hence,
similar explanation, other cases come to be included, in which the symptom
rtigo has not been present, but in which the phenomena point rather to car-
ailure as the chief cause of the derangement. In not a few of these last-
ioned cases, the patient talks of being giddy, but, on inquiry, it is found that
vertigo has never been experienced. In other cases, again, a mixed condi-
prevails, in which it is difficult to apportion the relative responsibility between
eart and the equilibrating apparatus.

t, entirely apart from the interest attaching to these anatomical details, the
anation of attacks such as those to which I refer has much importance by
ving the case from the dreaded category of epileptic attacks, and placing it

under a more hopeful aspect. It is true that, occasionally, the true vertigin disorder is so intense that there seems little to choose between it and true ep lepsy. A case of Menière's disease is described by M. Charcot (*Le Prog Médical*, December 11, 1875), in which the patient was restricted to the m absolute stillness in the recumbent position; still, as a rule, the cases now question have a more cheerful look-out, and, at the worst, are without some the most dreaded results of confirmed epilepsy, viz., loss of mental control. T diagnosis, however, is sometimes not easy; and I have met with several cases which the more unfavourable conclusion had been arrived at. It is with ref ence, more particularly, to the last-mentioned view of the subject that I inse brief note of the following case; simple as the symptoms appear, when a report had been obtained, the derangement was so severe for two or three d that, having nothing but the present condition before us, the diagnosis shif between epilepsy and meningeal hemorrhage. The history subsequently obtai from the patient made the matter clear.

J. B., a healthy-looking man, with gray hair and spare habit, was brought the Birmingham General Hospital, having been "taken in a fit." It was af wards found that he had been subject for the last two years to attacks, of wh the only account he could give was, that they began with violent belching: t what he thought was the wind came on, and seemed to go all over him, rende him tremulous, making his head very queer, and causing him to feel much d culty in keeping on his feet. He had never been rendered helpless by the att nor had he lost consciousness until the present occasion, when the unconsci ness was only partial, though, when seized in the street, he had felt great fe to his ability to reach his destination. He had never staggered, nor been scious of giddiness. The attacks were brief, though some had lasted for a qu of an hour. He was always relieved by a small dose of brandy. Sometime attacks had occurred in the night, and then he had been compelled to arou wife, in order to get the dose of brandy. He had been a healthy man, excep that some time ago he had indigestion, attended with pain across the chest. was placed on milk diet, and soon recovered. He was, however, very morb impressible. His habits had been strictly temperate. A certain degree of ri ity in the radial arteries was the sole evidence of fault in his physical organizat His optic disks were healthy. The commonest cause of the attacks was abstinence from food; but the most certain means of inducing them was affor by a meal of tea; he had been compelled in consequence to substitute cocoa. the morning of his present attack, he had had tea for his breakfast. He engaged in emptying boats, when he suddenly cried out that "he was bad;" did not fall, but was helped into the hut near the boat, and, having had s brandy, was conveyed to the hospital. In the out-patient room, Dr. Si found the patient unable to stand, and, suspecting that intracranial hemorrh had occurred, sent him into the wards. That was about 10 A. M. Dr. Ma the house-physician, found the patient sitting on a chair, having, every few m utes, attacks of fearfully violent eructation, effected with a loud noise; during intervals of belching, the man was only half conscious; he could not be made reply to any question, and hardly to protrude his tongue, which was very furr After a bath, he had an attack of apparent unconsciousness; he then lay on back, almost like an apoplectic; the pupils were dilated, and feebly sensitive light; respiration was stertorous; the cheeks were blown out and drawn in w respiration. The face was dusky, and there was profuse perspiration. T pulse was very soft and full, and was accelerated. It was some hours before recovered from this condition, and he was not fully himself until the followi morning; for two or three days he appeared dazed and confused. His recove eedy and complete. He had only an imperfect recollection of what had lace; he remembers being conveyed to the hospital and being placed in h, but there his memory becomes at fault. The attack just described ed on December 1st of last year. On March 6th he visited the hospital ct health. He had been taking liquor strychniæ.—*British Med. Journal*, , 1880.

Alterations in the Alimentary Tract in Pulmonary Consumption.

uigi Mazzotti (*Bulletino delle Scienze Mediche*, February, 1880) con- rom the preceding number his researches on the changes in the digestive hich occur in pulmonary consumption. Out of fifty cases, he found ulcer- esent more or less in thirty-seven. (See *Monthly Abstract*, April, 1880,) In one case only did he find tubercles. In twelve cases there were no whatever. In nine, however, of these the pulmonary lesions were com- ly slight, and were associated with other and more or less important . As regards the situation of the ulcers, the author divides them into) where one part only of the digestive tract was invaded; this was so as l the small intestine in eleven cases and as regards the large in five; (*b*) wo parts were involved, viz., in eighteen cases, both the large and small , and in one case the pharynx and small intestine; (*c*) where three parts olved, viz., in one case the stomach and small and large intestines; (*d*) our were involved, viz., in one case the tongue, pharynx, large and small . In all these positions the morbid process had commenced with tume- of the lymph-follicles, followed by ulceration, which spread from the mu- mbrane to the subjacent tunics. In the case of ulcers of the stomach, the ions present were those referable to ordinary catarrhal inflammation. In ases examined tubercles were found, with varying frequency and of vary- ances from the patches of ulceration. Subserous tubercles were found in , in which the typical lesions of phthisis were wanting. Tubercles of the membrane without ulcers were found in one case of phthisis, and in a cancroid of the scrotum. He concludes from these researches that it is ectly correct to speak of "tubercular ulcers of the digestive tract" as symp- of pulmonary phthisis or tuberculosis. Tuberculosis and tubercular ulcer- the intestines are not synonymous expressions.—*Lond. Med. Record*, , 1880.

Albuminuria.

w and very simple method of investigation has been introduced for the f the place of origin of albuminous exudations. It consists in causing the oagulation of the albuminous elements by heat or other means, and so hem for future examination. The first to make use of this method was and it has since been adopted by Posner, Ribbert, and Litten. ethod commonly employed has been the quick coagulation of the n by heat. This fixes it in the localities in which it existed during hereas other modes of hardening, instead of doing this, have the disadvan- extracting it. Boiling water hardens the fragment of tissue in a few s; its elements present no change; the chemical reactions with colouring are the same; and the fragment can be preserved in alcohol or chromic uids, with the sole difference from uncooked preparations that instead of aces being empty they are seen to be filled with coagulated, clear, finely ar albuminous masses. These are so striking that Posner asserts that no ination of a tissue infiltrated with an albuminous fluid can be regarded as exhaustive which is not controlled by this method. Applicable to various inv tigations, it is especially valuable in the examination of the kidneys. T slightest degree of albuminuria can, the same writer asserts, be demonstra anatomically by this method with certainty. The transuded albuminous ma can be fixed both *in statu nascenti*, and after exudation. They are seen characteristic aspect in the capsules around the glomeruli, and thence can traced into the urinary tubules. When the effusion is not merely from glomeruli, but also from the capillaries around the tubules, it can be seen tween the membrana propria and the displaced epithelium. In the large w kidney, for instance, the naked-eye appearance is seen, in preparations by method, to depend chiefly on distension of the capsules and urinary tubules albuminous fluid.

The information which this method supplies regarding the translucent fibri cylinders is of especial interest. Some facts have been adduced to prove that tube-casts arise by transformation of the epithelium of the tubules, but the re obtained by "cooking" suggest the opposite conclusion. Even in the hu kidney, in which the process is complex, distinct transitions are met with betw albuminous and homogeneous masses. Posner found that, three days ligature of the ureter, the kidney was distended and spotted with hemorrh and the examination by this method shows that the condition is due to quantities of exudation, partly serous, partly sanguinolent, partly in proce transformation, in homogeneous masses, and situated in part within the tub

Litten found that if the renal artery is ligatured, the kidney in two ho intensely congested with serous exudation, which, after the ligature is rem and blood allowed to flow through for twenty-four hours, comes away as cylinders. Chromic preparations show abundant exudation, inclosing cell the early stage of the formation of tube-casts can be traced as a fine netw fibres (due to the precipitation), and visible first close to the cells. Fro and other experiments, by producing venous obstruction, Posner con that the formation of tube-casts may be regarded as independent of cell-de tion.

The subject has lately been reinvestigated, after the same method, by Li He finds the methods of coagulation by heat and by strong alcohol give eq satisfactory results. Having first satisfied himself that, in the animals ex mented on (rabbits), the capsules around the glomeruli did not contain alb nous exudation, he tied the renal vein for two hours, and found throughout whole cortex the capsules raised by coagulated albumen, which could be tra in some cases, as far as the commencement of the twisted tubules. In cases a number of red blood-corpuscles were found between glomerulus and sule. The vessels themselves seemed to be intact, uncompressed. The ep lium of the tubules was normal, but within the tubes there was, in many pl the same material as filled the Malpighian capsule.

In another series of experiments the renal artery was tied for two hours. structure of the kidneys was everywhere intact. Within the capsules was same albuminous material, but in somewhat smaller quantity. Much intense changes were found when the artery had been tied for a time, and the blood allowed again to flow. The exudation within the capsules was greater, so as to press the vessels away from them, and it extended into tubules throughout their entire extent, the epithelium, however, within being intact. The epithelium of the capsules was much swollen, and p separated by the exudation.

It must, therefore, be regarded as certain that in mammals the alb transudes at the Malpighian capsules—a fact which Nussbaum first de l to be true of the frog. The question arises under what physiological or ogical conditions may the albumen transude in this situation? The transu-, Litten thinks, occurs under conditions which have this in common— e renal vessels undergo a transient dilatation of their calibre. He believes ter ligature of the artery this dilatation occurs when the blood is allowed r. Thus he explains the occurrence of albuminuria after section of the otor nerves, and not after section of the secretory nerves of the kidney, o its occurrence after some brain injuries. In all these varied states he only one common character, the dilatation of the vessels, and the conse-etardation of the blood-current through them. In acute inflammation he tes the escape of albumen to the same mechanism; in chronic inflamma- doubt changes in the wall of the vessel occur. Litten, from his experi- agrees also that the exudation of albumen is probably not confined to the uli, but takes place also in the tubules.—*Lancet*, March 20, 1880.

Treatment of Prurigo by Pilocarpine.

n the observation of the fact that sufferers from prurigo feel relief when retion of the sudoriparous glands is active—as, for example, in summer— ON (*Allgem. med. Centr. Zeitung*) has been led to try the preparations carpine, and of jaborandi itself, in this distressing condition. A very us series of trials have persuaded him of the beneficial action of this of treatment. In adults he uses a subcutaneous injection of pilocarpine, ribes a syrup of jaborandi. The patients, soon after the administration nedicine, are enveloped in blankets for two or three hours. In patients g from psoriasis the perspiration is very scanty, while in pruriginous s it is very abundant. The effects of this mode of treatment were, abate-f the accustomed sense of pruritus, softening of the skin, and diminished cy to relapse. In general the case did not last longer than a fortnight, very severe cases three weeks.—*Dublin Journal of Med. Science*, April, rom *Lo Sperimentale*, Gen. 1880.

Surgery.

Extraction of Metal from the Vitreous Body by the Magnet.

J. **Hirschberg** (*Berlin. Klin. Wochenschrift*, 1879, No. 46) brought lowing case before the Berlin Medical Society on the 15th of October

d sixteen years of age, when working in the smithy with his father, on the eptember, at 8 A. M., suddenly felt that his right eye had been hurt and t dimmed. Having travelled six and a half hours by road and rail, he en by Dr. Hirschberg at half-past 3 P. M. There was a wound in the two and a half millimetres in length and one millimetre and a half above p of the cornea, presenting some clear vitreous humour between its lips. ornea was plaited vertically. It was at once presumed that a foreign body enetrated into the eye. The eye having been bandaged, thorough rest in a ned room was prescribed. In the evening, the sight was said to be much ved; the wound was closed; the cornea was clear; the aqueous humour arent; the iris free; the pupil moderately dilated, and egg-shaped, with oint upwards: the iris was evidently dragged up to the wound, or adherent to the inner aperture of it; no prolapse, and normal reflexion from the pup A dark thread was seen in the vitreous body, tapering straight downwards fr the wound. On the patient being made to look down, a pretty large piece iron came into view, some distance behind the lens, in the lower part of vitreous body, black, irregular in shape, sharp-edged. The optic nerve retina were normal.

The state of things being unaltered the next morning, and not only the itself, but even its fellow, being thought to be in danger, the following opera was resorted to: Thorough anæsthesia having been induced, a semicircular c junctival flap was formed inwards from the intended line of incision, and refle back over its base towards the temple. The retractor was now inserted, and eye, by an assistant with forceps, turned inwards as far as possible. A meridi incision four millimetres in length was made through the whole of the membr by slow sawing movements with von Gräfe's cataract-knife behind the cil body in the direction of the equator, the edge of the knife being turned tow the latter. Vitreous humour showed in the wound, but did not escape. Ge pressure on the inner lip of the wound having proved unavailing, an ele magnet, resembling in shape the arm of a curved iris-forceps without teeth, inserted in the wound, with its point turned towards the sclera. As no effect obtained, the magnet was withdrawn and the incision lengthened to seven or millimetres with scissors. The magnet was inserted as before, only a little m deeply, and so twined as to bring its point nearer to the lower vertex of equator of the bulb. On cautiously withdrawing the magnet, it was now fo to have caught hold of a black splinter of metal, which issued with it from eye. A pad of cotton was gently pressed upon the eye, the fading anæst fully re-established, the conjunctival flap re-turned over the incision and by two sutures. Both eyes were properly bandaged, and the patient was into his bed. The fragment of metal was three millimetres by two by one metre in thickness, free from rust, with sharp and irregular edges, one side what convex, the other plane, and weight twenty milligrammes.

The next day, the eye was free from irritation, T — 2, the cornea sli plaited, the pupil contracted. On the second day, a drop of atropin solu was applied; but it was not before the evening of the third day, when the was able to make out the time on an ordinary watch, that the pupil bec dilated. The refracting media were now found clear, and the scleral cica left from the operation could be clearly distinguished. On the fourth day, sutures were removed, and a clear bead of vitreous humour was still to be at the point of the sclera where the metal had entered. About a fortnight the operation, the cicatrix was complete, the conjunctiva still a trifle swe over the incision. The small thread in the vitreous body then still observ gave way in another fortnight, when the patient was discharged. The aut goes on to indicate the exact details of the appearance of the fundus, and visual field, which are both represented by figures, surveys the literature on subject, in which Dr. McKeown, of Belfast, is assigned the place of honour, winds up with a description of the magnet employed by himself. — *Bri Medical Journal*, May 22, 1880.

Case of Complete Amaurosis from the Use of Salicylate of Soda.

Dr. FRANCISCO GATTI (*Gazzetta degli Ospitali*, February 29, 1880) rep a case of sudden and complete amaurosis, which lasted ten hours, and was induc by the medicinal use of salicylate of soda. The patient, a girl aged 16, was fering from acute articular rheumatism, for which 12½ grains of the drug prescribed every hour during ten hours. After taking this amount the artic

were relieved, but the patient was seized with deafness, noises in the ears,
omplete blindness. The pupils were widely dilated, and the sclerotic and
on each side highly sensitive. After perception of light had returned,
driasis still continued. The ophthalmoscopic examination generally gave
e results. Neither the urine nor the saliva yielded the characteristic re-
of salicylic acid in presence of ferric perchloride. The ocular symptoms
n all about ten hours, but left no permanent impairment of sight.—*London
Record*, May 15, 1880.

—

Transparent Cysts of the Eyelids.

RT sums up his conclusions (*Recueil d'Ophthalmologie*, Feb. 1880) as
these growths as follows: 1. A peculiar form of cystic tumour occurs on
lids, but it is decidedly rare; it seldom attains the size of a bean, and
contains a perfectly limpid fluid. 2. The most striking and constant
n in these tumours is their transparency. 3. They have nothing in com-
th hydatid cysts, and are totally distinct from them. 4. Their point of
not, as might be supposed, in the sudoriparous glands, but the sebaceous
, the hypertrophied walls of which secrete a serous fluid. 5. The best
nt consists in the excision of a portion of the follicle, and cauterization
undus of the *cul-de-sac* with a crayon of nitrate of silver.—*London Med.*
April 15, 1880.

—

Deaf-Mutism.

OUCHERON has lately read a paper at the Paris Academy of Sciences on
of treatment of certain infantile cases of deafness, or deaf-mutism. The
which he referred are those arising from naso-pharyngeal catarrh, causing
us of the Eustachian tube to swell and stop the passage; the stirrup-bone,
, being, through pressure of external air on the tympanum, made to press
on the liquid of the labyrinth, injuring the acoustic nerve. M. Bouche-
s chloroform to the child, and practises catheterism, insufflation of air,
ryngeal cauterization with a brush dipped in iodine solution.—*British
ournal*, May 8, 1880.

—

Adenoid Vegetations in the Naso-Pharynx, and their Treatment.

ner method of removing adenoid vegetations in the naso-pharynx has
ded by LANGE (*Monatschr. für Ohrenheilkunde*, Feb. 1880). Dr.
formerly assistant to Dr. Meyer of Copenhagen, whose work on this sub-
ell known, thinks that in treating these growths it is practically only
y to regard those situate on the roof and upper part of the posterior wall
harynx. He relies almost entirely on digital examination for the purpose
nosis in the first instance. After removal of the greater portion of the
, the rhinoscope comes into play. Following all the more recent
, the author recommends removal of the growths from the mouth, and
this purpose a ring-shaped knife, attached to a stem suitably bent. With
trument, the author removes all the growths at one sitting, and subse-
cauterizes the naso-pharynx about six times with solid nitrate of silver,
vals of five or six days. The removal of the growths is frequently fol-
y considerable temporary swelling, which renders the application of the
ouche impossible, and great care is therefore necessary under these cir-
nces to prevent the fluid from entering the ears. The author has never
y bad symptoms in the ears result from the operation. He attributes to
ni the merit of having convinced otologists of the necessity of being
r with the use of the rhinoscope.—*London Med. Record*, May 15, 1880.

Occlusion of the Larynx: Internal Laryngotomy.

Professor K. STÖRK relates, in the *Wiener Medizinische Wochenschrift* (46, 1879), the case of a boy aged 7, who three years previously had diphthe for which tracheotomy had been performed, and he had since worn an unfe trated cannula. Some time after the operation, he was brought to Dr. Störk consequence of having become dumb. Laryngoscopic examination showe normal condition of the parts as far as the interior of the larynx; beyond vocal cords, a *cul-de-sac* was noticed. The vocal cords moved, but with sound; there was a remarkable absence of secretion. Dr. Störk diagnosed c plete adhesion of the cricoid cartilage. On examination with a small trach speculum, a wall of mucous membrane was found to have been formed betw the larynx and trachea, arching over the latter like a dome. Dr. Störk co quently resolved to perform internal laryngotomy. For this purpose he use knife one-fifth of an inch long, set at a right angle to the hand, with which carefully divided the adherent parts from below upwards and from behind wards; this having been done, a specially constructed dilating apparatus applied. There was little hemorrhage during the operation; and the only culty arose from the narcosis. After the operation, the laryngeal opening hav been dilated and the tracheal opening closed, the patient was able to sp —*British Med. Journal*, May 8, 1880.

A new Subcutaneous Method of Operating for Removal of Growths from Interior of the Larynx.

A simple, and therefore excellent, plan of operating on laryngeal grow described by Professor ROSSBACH, of Würzburg, in the *Berliner Klin. We schrift*, No. 5, 1880. All the preparation required by the patient is th shall have learned to be laryngoscoped quietly. He sits before the oper the ordinary way, but with his head supported by a photographer's rest. holds his tongue himself with the right hand covered with a rough well-f glove, and must take care not at the same time to hide the middle line of his by his closed hand. The operator either holds the laryngeal mirror with hi hand, or, in the case of a very manageable patient, fixes it in position i pharynx by means of an appropriate stand. The mirror must illuminate larynx well, and give a clear view of the part to be operated on, as well as o lower end of the epiglottis and the anterior commissure of the vocal cords. the operation itself, a very sharp-pointed, delicate knife, with triangular and smooth cylindrical shank, is held in the right hand and pushed through median lamina of the thyroid cartilage, a few millimetres below the lower of the thyroid notch, exactly in the middle line, into the larynx. The pr distance of the puncture from the notch depends on the seat of the growth i particular case, and it varies from one to five millimetres below it. The poi the knife then appears above and close to the vocal cords. There are no bl vessels of any importance either on the anterior or posterior surface of the me lamina of the thyroid cartilage, so that no bleeding is to be feared; the hy cartilage also, of which it consists, is so easily penetrated even in old people, so seldom ossified, that scarcely any effort is required to make the knife enter larynx through it. With the laryngeal mirror the entrance of the knife ca watched, and its movements regulated with the greatest ease during the neces incisions, etc. The patient feels nothing except the external prick; he is conscious of the presence of the knife in his larynx, nor does it excite cough, as a rule, any desire to swallow. Should deglutition occur, however, it is u cessary to withdraw the knife, and the latter should be retained between and forefinger, the finger resting on the larynx, so that the hand and the nay follow the upward and downward movements of the thyroid cartilage. withdrawing of the knife the opening in the cartilage closes hermetically ; y skin-wound requires no other treatment than a small piece of plaster. A dull pain is all the patient feels after the operation.

essor Rossbach uses knives of different breadths of blade according to the the growth to be removed. Owing to their thin cylindrical shank they moved in any direction, and, if necessary, can be bent to meet special cases. nks his method applicable to a large number of operations which have o been performed by the introduction of instruments through the mouth, extreme simplicity seems to us to justify his estimate of it. He mentions . A. Eysell, of Halle, had previously suggested a somewhat similar plan, of however, he was ignorant until his colleague, Professor Gerhardt, told him In any case Rossbach claims the first removal of a polypus in this way. interested in the operation will find some valuable hints upon its previous nance on animals at the end of Professor Rossbach's paper, which our space t allow us to reproduce. The operating knife is also figured.—*Med. and Gazette*, April 10, 1880.

Resection of the Ribs in Empyema.

e current number of the *Birmingham Medical Review* is a paper by Mr. AM THOMAS, one of the surgeons to the Birmingham and Midland Free l for Sick Children, on the surgical treatment of empyema, as illustrated ral cases in which resection of one or more ribs has been practised. The recorded by Mr. Thomas is very marked. He has performed the opera- e times ; four of the children have recovered with expansion of the lung oration of the excised rib, in three others all discharge has ceased and the e in various stages of expansion ; another case is "doing well," and the se was almost moribund when operated on, and died six hours later from . The case of Dr. F. Taylor and Mr. G. Howse is also recorded in the pa- he object of the operation is to allow of full retraction of the ribs and efficient e of the pleural cavity. It is of course obvious, but yet not always borne , that an empyema can never be cured unless the cavity of the pleura is ted by the expansion of the lung, the displacement of viscera, or the fall- of the chest wall, or all of these together. But only when the lung ex- o its former size have we any right to speak of a "cure" having been lished ; in the other cases recovery may have resulted, but the patient is ippled, having a much diminished breathing power. We cannot keep sideration too constantly and clearly in view ; it is not enough to save the uch cases, we ought also to save the lungs, and it is as much a stigma on to allow a patient to recover with a collapsed useless lung, as to permit sis of the hip to occur in a false position. This is not a mere quibble, want of a clear perception of this point leads to errors in practice which ry disastrous results : patients with pleuritic effusion are left alone so long rious symptoms arise, there is a long delay before the fluid is withdrawn, anwhile the lung is being compressed and possibly bound down, so that it er fully expand again. We know that of late years paracentesis thoracis ome much more generally adopted and employed at an earlier period in ease than formerly, but we want still further progress in the same direc- The main issue to consider in any case of pleurisy is the injury to the lung, covery with a damaged lung ought never to be looked upon as a satisfac- rmination to a case. There is no period in the disease, after effusion has place, too early for aspiration of the inflamed pleura ; there is no consideration more pressing than the speedy removal of the force compressing the lung. These being our views, we look upon such an operation as resection of the ribs as evidence of failure in the earlier treatment of the case. The removal of a portio of a rib allows freer drainage than can otherwise be obtained, and no doubt per- mits of a more complete recession of the chest walls than is otherwise possibl and the bone is eventually reproduced; but we must again repeat that recour to it is an admission of failure to obtain a "cure," the effect of which is in ma cases as disastrous as the saving of a life at the expense of a limb.—*Lancet*, Ma 22, 1880.

Antiseptic Nephrectomy for Hydronephrosis of the Left Kidney in a Young Child; Recovery.

Dr. W. H. Day, Physician, and Mr. J. Knowsley Thornton, Surgeon the Samaritan Hospital for Women and Children, report (*Lancet*, June 5, 18 the following almost unique case which we transcribe in full.

A. B——, aged seven, a healthy-looking girl, was admitted into the Dors street branch of the Samaritan Hospital, under the care of Dr. Day, on Oct. 1879, suffering from an abdominal tumour, which was first noticed when she two years of age. No accurate history could be obtained, as the mother was de and the child for the last two years had been away from the father. She three sisters and one brother living, and they were all healthy. The child had whooping-cough and scarlet fever, but no bad effects followed either dis At no period had she complained of any pain or discomfort in her body.

On examination there was an abdominal tumour of irregular outline, and fr movable, rather firm in some places, but elastic in others. It was particu elastic and prominent between the umbilicus and pubis, where fluctuatio detected. The outline was not unlike that of a large multilocular ovarian and on deep inspiration it could be seen extending an inch above the umb The superficial veins were enlarged over the whole abdomen, and there considerable quantity of free fluid in the peritoneal cavity. There was no enl ment of the spleen or liver, which occupied their normal position. Traced b wards towards the left renal region, the tumour seemed as though it might sp from the left kidney. A coil of intestine crossed it from left to right cross and then from right to left. Midway between the umbilicus and pubis there a soft elastic fluctuant swelling to the right of the umbilicus, and between it the right anterior spine of the ilium the note was tympanitic (cæcum). lower ribs, especially on the left side, were much pressed outwards, and the cussion note was very resonant over both hypochondriac regions. The gir the umbilicus was 26½ in.; on the right side it was 12¾ in.; on the left, whe was most prominent, it was 14 in. There was no pulmonary or cardiac dis The urine was normal. It was stated that for a long time before admission patient had only passed urine once a day, and that the quantity was small.

Many opinions were expressed with regard to diagnosis: (1) Mr. Spe Wells thought there was distinct hydatid fremitus in the prominent part of tumour below and to the left of the umbilicus; he thought it might be remo (2) Dr. Champneys expressed a similar opinion. (3) Dr. Greenhalgh and Dr. Granville Bantock regarded the case as of ovarian or hydatid origin. (5) Savage considered the tumour renal. (6) Mr. Thornton also thought the tu renal, but the question of hydatid, of mesentery or omentum, ought not to be cluded. He was in favour of a careful antiseptic tapping with a fine trocar in or that the fluid might be examined. (7) Mr. Meredith considered the tumour due to hydronephrosis, or to hydatid disease; he also advocated tapping wit fine aspirating needle. (8) Mr. Doran thought it an ovarian cyst, with the tu

colon adherent along its upper portion, but was doubtful, and advised an
oratory incision.

ov. 4th. The bowels having been freely emptied by an enema, the child
narcotized with bichloride of methylene, and under the carbolic acid spray,
Knowsley Thornton introduced a fine trocar into the fluctuating part of the
ur, midway between the umbilicus and the anterior superior spine of the
, when six pints and a half of a brownish-coloured fluid were drawn off,
g an acid reaction and urinous odour. The puncture was dressed with
lized gauze, and a flannel bandage applied.

the following day the patient passed three pints of clear, normal urine, and
ext day forty-four ounces. The general health was undisturbed. After this
uantity diminished to nine ounces in the same space of time, till three weeks
the operation for removal of the cyst, when twenty ounces of clear, non-
inous urine were passed daily. On the 13th the cyst was fast filling up,
here appeared little doubt that it would be necessary to remove it.

Dec. 14th the cyst had refilled, and the circumference of the abdomen was
twenty-six inches.

Jan. 2d, 1880, the child was transferred to the surgical wards in Lower
our-street, and on the following day, bichloride of methylene having been
istered by Dr. Day, Mr. Thornton, assisted by Mr. Meredith and Mr.
, removed the tumour by abdominal section. An incision commencing an
above the umbilicus was carried down to its left side to three inches and a
When the peritoneum was reached it was caught up by artery forceps and
lly divided; the cyst was exposed, and slight adhesions round the tapping
ure were easily separated by the finger, great care being necessary, as the
vall was very thin. The small ovarian tapping trocar was used to empty it,
o difficulty was experienced in performing this part of the operation without
cape of any of the fluid into the peritoneum or over the incision. The cyst
ound to be inclosed between the layers of the descending meso-colon, the
nding colon having been pushed forward and to the right as the cyst enlarged;
gmoid flexure was also much displaced, and lay across the lower part of the
and between it and the bladder; the latter was distended with urine, and
onsiderably above the pubes. Great care was required in enucleation, which
erformed through an opening made in the capsule to the inner side of the
nding colon. No distinct ureter could be found, but a thin cordlike structure
l downwards from the lower part of the cyst, and, becoming intimately con-
l with the parietal peritoneum, was lost in its reflection on to the fundus of
adder. The cyst having been thoroughly enucleated to its base, was turned
, and the renal vein could then be *seen* and the artery *felt* pulsating behind
blunt aneurism-needle was passed between them threaded with a double
re of No. 1 Chinese silk, and they were tied separately about an inch from
orta. Another ligature of No. 2 Chinese silk was then tied round the whole
le on the distal side of the first ligatures, and the cyst cut away a good half
from the ligatures. There was very little sponging necessary, even in the sac
f which the cyst had been enucleated, and none of the general peritoneum.
the sponging the parts fell very nicely together, so that on looking into the
nen there was nothing to indicate where the cyst had been removed. Two
shreds of capsule were ligatured and cut away; all the other bleeding points
merely squeezed for a time in Wells's artery forceps. The incision was
l with No. 1 Chinese silk sutures, and the usual gauze dressing without pro-
ve applied.

he operation was prolonged by the little patient taking the anæsthetic badly,
retching a good deal, and by the care required in the enucleation. It occupied

an hour and a half. From first to last every detail was carried out strictly according to Lister's method. At 9 A. M., half an hour before the operation, the patient's temperature was 99.4°, and twenty minutes after she was placed in bed it was 97.8°, pulse 116, respiration 28. At 11.45 six drops of laudanum were injected into the rectum, and the same quantity again at 2 P. M. At this hour three ounces of clear, pale urine were drawn off by catheter. It was exactly like that examined the day before the operation, and deposited white urates. She was sick at 2, 3.30, 4.20, 4.30, 5.30, 8, 8.30 P. M., and at midnight. At 3.30 P. M. the pulse had risen to 136, and at 9.30 to 150; respiration 32; temperature 101.6° (the highest point reached at any time during the case). At 3.30 P. M. about an ounce of urine was drawn, dusky in colour, and containing some small black clots. From this time till 3 A. M. on the following morning about an ounce was passed without the aid of the catheter every hour and a half, each specimen being bright-red, as if almost pure blood. At 5.30 P. M. a large linseed-meal poultice was applied over the right kidney. At 11 P. M. two ounces of beef-tea were injected into the rectum, with six grains of bromide of potassium; as the little patient was very restless, a similar injection was given every two or three hours during the next thirty-six hours. At 3 A. M., after the operation, rather more urine was passed quite free from blood, and containing urates as before the operation; and from this time onwards a fair quantity of healthy urine, quite free from albumen, was passed, generally from a pint and a quarter to pint and a half, or more, in the twenty-four hours. During the first twenty-fo hours the total quantity, including the bloody urine, was twenty ounces.

The patient was sick at intervals till the morning of the second day, when ceased, and she began to take bread and milk, and milk and lime-water freel After the urine became normal, eight drops of laudanum were given occasion per rectum, instead of the bromide. At 9 A. M. on the first day the temperat was 98.8°; pulse 140; respiration 26. At 10 P. M., temperature 99.6°; p 132; respiration 16. At 10 A. M., second day, temperature 99.4°; pulse 1 At 9 P. M., temperature 100.4°; pulse 114. The bowels moved on the four day. All the sutures were removed on the sixth day, when the wound was fou well united by first intention. From this time the temperature was normal a the pulse about 96. She was moved into the convalescent ward on the nin day, and was soon after up and running about. She would have left the hospit for a convalescent home at Brighton on the twenty-third day, but her departu was delayed by an attack of ringworm.

Remarks.—On the day following the tapping the patient passed three pints urine, and two pints on the second day. This shows that there was some symp thetic irritation of the right kidney. The excessive congestion of this remaini kidney after the major operation may then have been to some extent due to th same cause. The bloody urine was, however, highly charged with carbolic aci and remained for some days free from putrefaction, while some of the clear uri standing beside it was putrid in twenty-four hours. Both specimens were similar open vessels, and both were tested from time to time by odour a microscopic examination for bacteria. The ordinary urine was highly offensiv and swarmed with bacteria; the bloody urine got gradually darker in colour, b remained free from odour, and several days later contained no bacteria, but so penicillium.

It seems to us probable that the extreme congestion of the kidney was d rather to the carbolic acid than to the sympathetic irritation. It is obvious difficult to assign to each factor its share, but we know that there is often co siderable congestion of the kidneys after ovariotomy, and that this has bee decidedly increased in severity since the introduction of Listerism in abdomin surgery.

The cyst was shown at the Pathological Society as a fresh specimen, and we therefore reserve all description of it for the "Transactions." The patient was shown in good health some weeks after the operation, at a meeting of the Medico-Chirurgical Society. The extremely thin condition of the front of the cyst wall seems to us fully to justify our decision that the time for operation had arrived: a very slight accident would have been sufficient to cause extravasation of the cyst contents into the peritoneum.

There are three very important points worthy of special attention: 1. The safety of the antiseptic exploratory tapping, evidenced by the absence of all subsequent constitutional disturbance. 2. The rapid and satisfactorily convalescence after so prolonged and serious an operation on a young child, also greatly due to the antiseptic precautions. 3. The speedy disappearance of blood and albumen from the urine after such a severe congestion. The urine was frequently examined during convalescence both by tests and the microscope, and was always quite normal.

Hydronephrosis; Nephrotomy; Recovery.

Dr. THOMAS SAVAGE, Senior Surgeon to the Hospital for Women, Birmingham, records (*Lancet*, April 17, 1880) the following case:—

Mary N., aged forty-six, married twenty-one years, with five children, came s an out-patient October 28, 1879. She had noticed a lump in her abdomen r a year and a half; is quite regular, the last period being a fortnight ago. Has ffered from prolapsus uteri, for which she has worn various pessaries. She is in, and looks careworn.

On examination there was a tumour about the size of a fœtal head, occupying e right lumbar and umbilical regions. It was elastic, very movable, and pain- s, clearly a cyst, and appearing to spring from the right kidney. The urine s examined several times, and found to be normal. There was no history of s or blood in the urine, nor of injury in any way, and there was no appearance malignancy, but there was an indistinct history of renal colic, to which the tient referred as having occurred about three or four years ago, and which was arked by intense pain on the right loin, frequent micturition, and the necessity r constant application of hot fomentations. On repeated examinations, seeing at it sprang from above and had clearly no reference to the pelvis, that pressure the right kidney pressed it forwards, and that there was resonance on percus- on over one portion (the lower) of it, the tumour was diagnosed as a hydrone- rosis, with a fairly long mesonephron. Very curiously, it was said to become aller at the menstrual periods. As time went on the patient was sure the ab- men was enlarging, and this, together with the fact that she was getting inner, and was now (January, 1880) quite unable to do her household work, duced a recommendation to come into hospital and submit to an attempt at moval, or at all events, to allow us to make an exploratory incision.

On January 16, the operation was performed, which consisted of a median in- sion, extending from about two inches above to two inches below the umbilicus. he tumour now exposed was seen to be cystic, and was covered by the upper yer of the meso-colon. It was tapped, giving exit to a clear, watery fluid; un- rtunately this got mixed with blood, and was thrown away, and so neither the uantity nor the quality could be ascertained. When the hand was passed down the base it was found that the attachment was very broad—*i. e.*, thicker than e's wrist—and it appeared impossible to tie the artery and the vein, as also tie the mass in bulk, at so great a distance, deep in the abdomen, and close to he spine. The wall of the cyst on the outer and front part was made up of true renal structure—*i. e.*, the dilated pelvis of the kidney, in which were seen the enlarged calyces and papillæ. The other part of the cyst-wall was evidently made up of two portions: an outer, being a continuation of the capsule of the kidney; and an inner, apparently derived from the lining of the enlarged pelvis. The hand was passed into the cyst in search of a calculus in the ureter, but none was found, and it was then sponged out with carbolic solution. A wire clamp was applied about the middle of the collapsed cyst, and about one-half of the distal portion—*i. e.*, about one-fourth of the whole mass of the cyst—was cut away, leaving one-fourth still attached to the distal side of the clamp. This large mass was left for the sake of security against slipping. Perchloride of iron was applied to it, and carbolized lint applied as dressing. About the fourth day afterwards there was noticed a slight welling up of clear fluid in the centre of the stump, which appeared likely to eventuate in the presence of a persistent urinary fistula. The clamp was cut away on the twenty-third day, and the sloughing stump gradually cleaned, so that the patient left the hospital on March 1st.

When seen again on March 15, at my house, the wound had cicatrized with the exception of an area about the size of a threepenny piece, at the bottom of which was a sinus, into which a probe passed for two inches directly backwards and without pain or bleeding. The patient stated that there was a daily discharge of clear fluid of from a tea- to a tablespoonful in quantity. She appeared to be quite well in herself, and there was no tumour to be felt. She expressed herself as being better, and much more comfortable than before the operation.

Remarks.—The surgery of the kidney has of late attracted a considerable amount of attention, more especially with regard to the subject of nephrotomy; and several cases have recently occurred which tend in the direction of making it a justifiable and recognized operation. This has no doubt been brought about by the greater safety of abdominal section now compared with what formerly obtained. It may be deemed suitable in some few cases, in the early stages, of encephaloid and sarcoma; in hydronephrosis, as in the cases related; and in pyonephrosis, where the patient is in a state of hectic, or rather, before that stage, if possible, has come on; and for the removal of calculus in the ureter or in the pelvis.

There appear to be certain difficulties connected with the operation which have occurred to my mind since I operated on the above case. First, there is the thickness of the so-called pedicle or base, which at so great a depth may prove a considerable hindrance to successful ligature and subsequent cutting away. Of course the clamp is out of the question for the entire removal of the kidney, as the mesonephron would seldom, I imagine, be long enough to be brought up to the abdominal wall; and kidney tumours are often very deceptive in this respect, appearing to be freely movable in all directions nearly all over the abdomen, but found to be in reality rather firmly bound down. The clamp could be applied only to the tumour itself, as in my case, and then it is a question how far the part of the cyst left attached may not continue to be a secreting surface, and so the patient, perhaps, be no better for the operation, or leave a fistulous tract, which, though relieving a hydronephrosis, is, to say the least, not a pleasant accompaniment to one's ordinary life troubles. Secondly, there is the difficulty, I imagine, in many cases of having to pass a ligature round so short a vessel as the renal artery and vein are; and, thirdly, there is the question whether, when a ligature has been passed, the shortness of the vessel, and therefore the close proximity of the ligature to the great vascular trunks, will not prevent thrombosis occurring in the proximal side of the ligature, and hence permanent occlusion. I am not prepared to answer these points, but they are such as have occurred to me in thinking on the subject.

The cases reported by Simon, Czerny, Martin, Zweifel, and more recently by

Knowsley Thornton, and A, E. Barker, will do much to bring nephrotomy and nephrectomy before the profession; and the foregoing case is recorded with the same view.

Transverse Perineal Urethrotomy in Obstinate Strictures.

Practical surgeons have long been aware of the difficulties attending external urethrotomy in cases of obstinate and old-standing stricture. Dr. Ruggi (*Bulletino delle Scienze Mediche*, February, 1880) gives particulars of two cases in which, unable to find the urethra by the ordinary longitudinal incision, he had recourse to a transverse one, with complete success. The first case occurred in an individual, aged 54, whose urethra from the meatus to the bulb was impermeable to the smallest bougie. The author, considering that in such a case Syme's operation would be unsuitable, laid bare the perineal triangle formed by the corpora cavernosa, cut through the soft portions at the base of this triangle, carrying his knife parallel with the fascia media, and taking care not to go sufficiently deep to divide the dorsal vein of the penis. The urethra was at once recognized by the thickness of its walls, though the canal was so contracted as scarcely to allow the smallest-sized instrument to pass into the bladder. In the second case, the author had succeeded in passing a small bougie as far as the seat of the stricture, but here it doubled upon itself, and could not be made to proceed further. The patient was aged fifty-three, and his perineum was the seat of several fistulæ. In this case, the perineal incision was crescent-shaped, and measured ten centimetres. The appearance of the parts was so altered that the longitudinal incision did not enable him to find the urethra; this, however, he discovered readily enough on making a large and deep transverse cut. The portion of urethra anterior to the wound was dilated from behind forwards by the urethral dilator, and a gum-elastic catheter with its stylet by this means passed. The perineal fistulæ were slit up, and as much of the brawny cicatricial tissue removed as possible. The patient left the hospital, after a stay of two months, perfectly cured. The author gives certain directions for this operation; he makes his external incision, guided by the raphe if this still exists, if not, then as nearly as possible in the position where he thinks it ought to be. Hemorrhage is best restrained by Péan's hæmostatic forceps. When he considers that the level of the urethra has been reached, he enlarges the margins of his incision, and changes it from a longitudinal into a transverse one. He points out that in this procedure there is little danger from hemorrhage from either veins or arteries, inasmuch as the median artery of the perineum, the arteries of the bulb, and other vessels, have, in the majority of cases, been obliterated by the periurethral infiltration. Should hemorrhage, however, supervene, the temporary application of the hæmostatic forceps will always be found sufficient to check it.—*London Med. Record*, May 15, 1880.

Inguinal Castration.

The following *résumé* is given in the concluding portion of an original memoir on castration in inguinal ectopia by Monod and Terrillon of Paris (*Archives Générales de Médecine*, Nos. 2 and 3, 1880). 1. Inguinal castration is not a dangerous operation, and in a large majority of cases the patient recovers. 2. Peritonitis is not, as has been maintained, an inevitable and constantly fatal consequence of the operation. It is, indeed, an unfrequent result. It was observed but in three of fifty cases, and in one only of these was it fatal. 3. The indications of inguinal castration need not sensibly differ from those of scrotal castration. 4. In cases of tumour, the operation may be practised with less hesitation, since degeneration of the misplaced gland is most frequently of a cancerous nature, and the inguinal testicle is in all cases incapable of generative function. 5. The operation could, and indeed should, be performed at an early period, with the hope of preventing a relapse, which hitherto has been of almost constant occurrence. 6. Inguinal castration is indicated when the misplaced testicle is painful or when it is the seat of serous or repeated inflammatory affections (pseudo-strangulation). The inutility of the organ with regard to its function, is a point in favour of intervention. 7. The operation is an easy one, and does not, a a rule, need the employment of any special proceeding.—*London Med. Recor* May 15, 1880.

—

On the Treatment of Lateral Curvature of the Spine by Steel Supports, Plaster-of-Paris Jacket, and the Poroplastic Jacket.

At a late meeting of the Royal Medical and Chirurgical Society (*British Med. Journal*, May 29, 1880), Mr. Wm. Adams read a paper on this subject. H alluded to the great change in the treatment of curvatures of the spine, both angular and lateral, during the last three years, in consequence of the method introduced by Professor Sayre of New York, *i. e.*, the application of the principle o extension, by suspending the patient from the head and arms, and then applyin a plaster-of-Paris jacket during suspension. The author did not propose to spea of angular curvature from Pott's disease, further than to say that it was in th class of cases that the advantages of the plaster-of-Paris jacket were most co spicuous; and his experience led him to confirm all that Professor Sayre h claimed for it; but in the treatment of lateral curvature, Mr. Adams differ from Dr. Sayre, and believed the plaster-of-Paris jacket to be as useless and i jurious in this class of cases as it was useful in cases of angular curvature.

For practical purposes, the author arranged cases of lateral curvature in th classes, viz., 1. Physiological curves; 2. Confirmed structural curves; 3. Co mencing structural curves. In forming a diagnosis between these three clas the importance of the stooping position as affording evidence of the existence rotation of the bodies of the vertebræ was particularly insisted upon, attenti being directed to the symmetrical relations or otherwise of the angles of the ri in the dorsal region, and of the transverse processes in the lumbar region, rathe than to the spinous processes, the apices of which might preserve their normal straight line in relation to one another, without any lateral deviation, whilst rot tion of the bodies of the vertebræ might have taken place to a considerabl extent, rendering the case incurable. This fact was illustrated by a specime exhibited to the society by Mr. Adams, and described in a paper published wit illustrations in vol. xxxvii. of the *Transactions* of the Society. In the cases o commencing structural curve, in which probably the intervertebral cartilages onl had suffered from unequal compression, arranged in the third class, and formin an intermediate group between the first and second classes, the spinal curvature was much more apparent in the standing than in the stooping position; although, in the stooping position, it did not completely disappear, as in the physiologica curves. Some evidence of commencing rotation was afforded by a slight poste rior projection of the angles of the ribs on one side, and depression on the other and a similar deviation as regards the transverse processes in the lumbar region when the patient was examined in the stooping position.

With regard to treatment of cases in the first class, or physiological curves, no mechanical treatment by any form of spinal support should be given, but reliance should be placed entirely upon physiological means, such as gymnastic exercises, partial recumbency, and attention to the general health. In some cases, an elastic brace attached to stays might be used. In the second class, of confirmed structural curves, mechanical support of some kind must be resorted to, and continued during the period of growth, in the hope of preventing increase and obtaining some improvement in the curvature; but confirmed lateral curvature, whether slight or severe, with its adapted series of structural changes, was essentially incurable. The most efficient retentive spinal support was an instrument made with a pelvic belt and spring plates attached to vertical bars at the back, without any mechanism requiring alteration by the surgeon. In some favourable cases for improvement, the stronger spinal instrument, with steel plates attached to levers, and adjusted by rack-and-pinion movements, might be used with advantage. Sayre's plaster-of-Paris jacket had been largely employed in these cases; but from what the author had observed in the practice of others, he condemned its application on the grounds that it failed as a curative agent, the gain in height by extension being quickly lost; that it weakened the spinal muscles by its constant use, and hindered gymnastic exercises; that it restrained respiratory movements, and prevented active exercise; and that it was an unnecessary restraint at night, and interfered with bathing and cleanliness. The poroplastic ket, which, when softened by steam, was applied in the same way as the ster-of-Paris jacket during suspension, was free from the disadvantages of the r, as it could be removed at night, or at any time for the purpose of gym- ic exercises. etc. It acted as an efficient and light retentive support in many of incurable curvature. Commencing structural curves formed the only ble cases of lateral curvature; and for these the author recommended a com- tion of mechanical support, gymnastic exercises, and partial recumbency. this combination of physiological and mechanical means, the further progress rvature would be arrested, and the best opportunity afforded for recovery such slight structural damage as might have already occurred.

r. **BRYANT** said that Mr. Adams's observations were consonant with what felt by most surgeons. On one point, however, there might be difference of ion, viz., as to the time when curvature ceased to be curable by physiological ns, and passed into the incurable stage, requiring artificial supports. He ld delay assuming the commencement of the incurable stage as long as possi- In many cases of lateral curvature, recovery took place in a remarkable ree. He approved of the means of diagnosis recommended by Mr. Adams. had been accustomed to examine the patients in the stooping position, with hands on the back of a chair. He agreed that the plaster-of-Paris jacket not fitted for lateral curvature; though in some rare instances, of which he seen one, it was the only thing that would support the patients. He would discard the iron apparatus. The poroplastic jacket was preferable to any r; and the addition of steel bars to it, as recommended by Mr. Adams, was doubt an advantage.

Amputation in the Aged.

In the *Centralblatt für Chirurgie* for January 10, Dr. **MAX OBERST** commu- ates a paper detailing the results of the amputations performed in Prof. Volk- nn's clinic at Halle, upon persons of more than fifty years of age. Until ently, he observes, the generally admitted maxim, founded on long experi- ce, prevailed that the results of operations were influenced to a great extent age; and those performed in old persons turned out much more unfavourably n those which were performed in the bloom and vigour of life. The condi- of the cellular tissue exposed it to phlegmon, while the unfavourable cir- stances of the circulation in the aged led to gangrene of the flaps, and conse- ent putrefactive infection. Some surgeons laid down the diminished power of resistance and the increased "vulnerability" of old age as contraindications the operation. It is only since the introduction of the antiseptic system that erroneousness of these views has been shown, by proving that the age of patient exerts no influence on the course or issue of amputations, providing two circumstances be certainly avoided—the septic process and the septic fe arising from it, and a great loss of blood. During the vital energy of youth b sepsis and loss of blood, to a certain extent, can be resisted; while a s amount of these may be too much for the aged, breaking up their strength leading to a rapidly fatal termination. So that if we wish to place all ages an equality in relation to recovery after amputation, we must therefore gu effectually against the origin of the septic process and a considerable loss of blo Both of these we are now happily able to do by means of the Listerian treatm of wounds and the application of Esmarch's bandage.

In proof of what is advanced above, statistics of the Halle clinic may cited, comparing the results of amputations treated antiseptically, without re ence to age, with those which were performed on persons above fifty years Of 220 patients upon whom amputation has been performed since March, 18 9 died, or 4.1 per cent.; and of the 48 patients who were more than fifty ye of age, 2 died, or 4.17 per cent. In other words, the results, as life was c cerned, were not influenced by age. Of these 48 patients, 30 were betw fifty-one and sixty years of age, 13 between sixty-one and seventy, and 4 betw seventy-one and eighty. One patient upon whom amputation of the thigh performed, and who recovered, was eighty-four years old. Of the 48 amp tions 7 were of the forearm, 6 of the arm, 1 disarticulation of the should partial amputation of the foot, 13 of the leg (with two deaths), and 14 of thigh. In one of the fatal cases, amputation of the leg for senile gangrene seventy-four), death was caused by tetanus, a complication with regard prophylaxis of which we still are powerless. The second death occurred amputation of the leg for injury in a man (aged fifty-six) addicted to the alcohol. He died, with the wound in a completely normal condition, sixty after the operation, without ever having completely recovered from the narc The course of the wound in all the cases was unattended with reaction, no p mon, suppuration of bone, or phlebitis occurring. In one-half the cases abs union by the first intention took place, and in the remainder union was dela by slight gangrene at the edges of the flaps or by small suppurating fistulæ.

In the above comparison there have been excluded complicated cases in w amputation has been performed during existing sepsis, amputations coexis with other serious injuries, double amputations, cases in which the patients died of diseases which certainly had no connection with the operation, and joint operations.—*Med. Times and Gazette*, May 15, 1880.

Incomplete Lateral Dislocations at the Elbow.

In a contribution on incomplete lateral luxation at the elbow (*Centralblatt Chirurgie*, No. 9, 1880), Dr. Otto Sprengel, of Halle, states that the freq occurrence of this form of injury has never been fully recognized. In the majo of cases the luxation is not diagnosed, and consequently not reduced; and subsequent treatment is often so unsuitable that the patient retains a more or stiffened, and, not unfrequently, a completely ankylosed joint. The bones the forearm may be displaced either to the outer or to the inner side. In former case, the greater sigmoid cavity surrounds the capitulum instead of trochlea, and the head of the radius rotates freely in the position it occupies luxation outwards. In partial luxation inwards the head of the radius is in co

ct with the trochlea, and the margin of the sigmoid cavity stands away from
s articular surface. The internal condyle of the humerus is completely or
ost completely covered by the olecranon, whilst there is abnormal prominence
the external condyle. In luxation outwards the most prominent sign is dis-
cement of the head of the radius, the articular surface of which can be readily
. On careful digital examination of the joint, a portion of the trochlea may
made out near the inner condyle. The diagnosis is not usually attended with
culty, but when the patient is very young, and the injured joint is much
llen and bruised, it will be necessary to make the examination under chloro-
m. Which of the two forms of partial luxation, the outer or the inner, occurs
re frequently has not yet been determined. According to Hahn, of Stuttgart,
o was the first surgeon to direct attention to the frequent occurrence of partial
eral luxation at the elbow, the displacement of the bones of the forearm is
ost always to the inner side. Of five specimens of lateral luxation, removed
esection of the elbow, in consequence of ankylosis, Hueter found in all that
displacement had been to the outer side. Volkmann found external displace-
t in all the seven cases of partial lateral luxation of the elbow that came under
otice in 1873. An interesting complication of partial luxation intervals was
described by Hueter, who in each of his five specimens found that the inner
ndyle had been broken off, and that it rested in the groove of the trochlea,
s to form a serious impediment to reduction. Dr. Sprengel reports two
esting cases from the clinique of Professor Volkmann; one a case of old
ion of the elbow inwards, with ankylosis of the joint, which was treated by
tion; the other a case of luxation outwards, in which, owing to secondary
ration of the integument, the condition of the injured joint and the altered
ions of the bones could be directly observed.

e patient in the first case was a man, aged 25, who seven months previously,
travelling in South Africa, far from surgical aid, had received a severe in-
to the left elbow through the overturning of a wagon. After the gradual
ppearance of a large swelling about the seat of injury, the joint became stiff,
the forearm quite useless. On his return to Europe there was found to be
rmal prominence of the external condyle of the humerus. The internal
dyle was covered by the olecranon, and could not be felt. At the request of
patient, the ankylosed elbow was resected. Subsequent examination of the
oved joint confirmed the previous diagnosis of partial luxation inwards. The
itulum was apposed to the trochlea, and the ulna had been removed so far
ards that nearly half the sigmoid cavity remained free from contact with this
ular surface. On this free portion of the sigmoid cavity, and connected
the articular cartilage by fibrous tissue, was a piece of bone detached from
epicondyle. Firm fibrous adhesions bound together the opposed surfaces of
humerus and the bones of the forearm. A girl, aged 7, received an injury
the elbow, which was diagnosed as fracture, and treated by the application of
ypsum bandage. On the removal of this bandage five weeks afterwards, a
e opening was found in the integument, through which the inner condyle and
ortion of the inferior articular cartilage of the humerus protruded. The head
the radius could be plainly felt below the external condyle, the ulna had been
placed outwards, and the outer half of the sigmoid cavity embraced the capit-
m. The luxation was reduced under chloroform, six weeks from the date of
injury. Before the bones were replaced in their normal position, most of the
ured joint could be exposed to view, through forcible abduction of the fore-
m, and still further protrusion of the inner condyle through the wound.

From 1873 to 1879, thirty-two cases of partial lateral luxation at the elbow
ere observed in the Halle surgical clinic. There can be no doubt, Dr. Sprengel

states, that Hahn was quite right in his opinion that this form of injury is of frequent occurrence, especially in childhood. In eighteen of the twenty-one c recorded by Hahn the patients were children. Of the subjects of the thirty- cases collected by Sprengel, four were adults and twenty-eight between the of two and sixteen years. The injury was an inward luxation in twenty, an outward luxation in the remaining twelve cases. In fifteen cases the lesion quite recent; in each of these the luxation was reduced, and almost always the administration of chloroform.

The usual method of reduction consisted first in bending the forearm later so as to increase the extent of the displacement. By next moving the limb opposite position, and through direct pressure on the joint, the luxation c be reduced in most instances without much difficulty. In one only of the se teen cases of old luxation could the bones be replaced. This was an instanc luxation inwards of eight weeks' standing. In the remaining cases the object of the treatment was the removal of the ankylosis, or at least an imp ment in the condition of the joint. In two cases of old luxation inwards, in reduction could not be effected, the functions of the injured joints were al completely restored after a treatment consisting in forcible rupture of adhe and passive movements of the limbs. In some of the remaining cases a extent of movement was thus attained, whilst in others the ankylosis wa complete to be relieved by any treatment short of resection of the joint.—*Lo Medical Record*, May 15, 1880.

Subcoracoid Dislocation of Humerus without Rupture of Capsule.

Mr. FREDERICK S. EVE describes the following case of subcoracoid disloc of the humerus without laceration of the capsule, and with an indentation o posterior surface of the head of the humerus; and made some remarks o mode of production of fracture of the anatomical neck with dislocation.

Thomas B., aged 36, was knocked down by a train, while at work on the On admission to St. Bartholomew's Hospital, he was found to have sustai subcoracoid dislocation of the right humerus, presenting the ordinary charac The dislocation was readily reduced by traction with the heel in the axilla. died twelve hours after the accident, from injuries to the thorax At the *mortem* examination, except some laceration of the lower part of the deltoid, muscles of the shoulder were found to be not damaged. The joint was unope but, on incising the capsule, it was found to have been detached from the ante margin of the glenoid cavity, but remained continuous with the periosteum. the posterior surface of the head of the humerus, at the margin of the artic cartilage, a deep vertical indentation or groove was seen, into which the ante margin of the glenoid cavity accurately fitted. Mr. Eve said that the injury probably produced by direct violence. He had been unable to find on reco single case of traumatic dislocation in which the joint was not opened. groove or indentation was, doubtless, from its position and shape, produced the forcible impact of the humerus against the anterior margin of the gle cavity. Malgaigne, who mentioned two specimens of old dislocation forward which somewhat similar grooves had been formed by attrition, thought that t were sometimes produced as in the case related (*Fractures et Luxations*, p. 4 An easy explanation of the mode of production of fraction of the anatomical n with dislocation of the head, was suggested by this case, for, if the blow had b sufficiently forcible, the head would have been chipped off by the anterior m gin of the glenoid cavity, and would then have been displaced forwards. explanation was also given of the cases of impacted fracture of the anatom eck, with rotation of the head of the humerus on its axis, which was borne out several particulars by the two cases recorded by Mr. R. W. Smith (*Fractures d Dislocations*, pp. 196 and 197). In both these, the head was displaced wards.—*British Med. Journal*, May 15, 1880.

—

"*Bone-setting.*"

At a recent meeting of the Clinical Society of London (*Lancet*, April 17, 0). Mr. Marsh reported the following cases of bone-setting:—

No. 1. A countryman, aged fifty, dislocated his shoulder. The dislocation at once reduced, and the arm bandaged to the side. Nine weeks afterwards came to London for advice. It was found that the limb was so stiff that he ld not move the elbow more than two or three inches in any direction; and movement, whether on his part or during examination, produced great sufg; and he complained of constant severe aching from the shoulder to the w. It was noticed, however, that the joint was quite free both from heat swelling. When he had taken gas the scapula was fixed, and the humerus fully rotated on its long axis in the glenoid cavity, and then carried, in a s of short jerks, through all its natural range of movement. Numerous esions around the joint were felt to give way. He now lost much of his pain, could move his arm freely except in an upward direction. A fortnight later rm was carried, while he was under gas, freely above his head; after this is pain ceased and he recovered the full use of his limb.

o. 2. A man, aged twenty-four, in jumping from a cart twisted his foot r him. Great pain and swelling followed, and the limb from the instep to iddle of the calf came out, he said, "all black and blue." He was laid up fortnight, and then took to walking with a stick. Eight months afterwards me to St. Bartholomew's Hospital. The joint was still swollen, and the of severe pain if weight was thrown upon it. He had gone from hospital to ital, and been liberally supplied with bandages, elastic stockings, liniments, the inevitable tincture of iodine; but he got no better. The ankle was d free from unnatural heat, indeed it was unnaturally cold; the skin was h and shiny, and the outlines of the joint were obscured by brawny swelling. heel was a little drawn up, and flexion and extension were almost entirely He took gas, and the joint was carried by short jerks through all its ral range. Numerous adhesions in the sheaths of the surrounding tendons felt to give way. Within an hour he walked freely about the ward, and next morning walked from Hackney to the hospital and reported himself y to go to work on the limb. Six months later he came with the ankle n out of order. He said he had been quite well till three months before, n the joint had become painful and weak. On inspection, nothing could be d amiss, and he was advised to have the part strapped, and to rest it. He, ever, said he was sure if it were "bound" it would be all right. Gas was n, and the joint was carried into full extension and full flexion. During ion some slight adhesions were felt to give way. He wrote next morning to that he had been walking on the limb, and found that he could now do so hout either pain or limping.

No. 3 was a case of a similar character. A man, aged forty-five, could bear weight on his ankle nine months after a severe sprain. The joint was quite from heat. All his symptoms disappeared when the ankle was flexed and tended under gas; and in less than a week he was quite well.

No. 4. A lad, aged seventeen, of strumous family, was reported to have hipease. He could bear no weight on his limb, and the thigh was flexed, abducted, and rotated outwards. There was deep-seated pain at the back of the joint on any movement, and tenderness on pressure in this situation. There was no swelling. On examination, it was found that the hip-joint was sound, but it was believed there was strumous periostitis of the innominate bone beneath the external rotator muscles. He was told to rest, to have a course of blisters, and to take cod-liver oil. Three months later, as he was no better, he was taken to a bone-setter, who moved his limb. After this he lost all his pain, and in a week was "all right." Just twelve months later, having in the interval been quite well, he was, on rising quickly from his chair, seized with his old trouble. He had great pain, and felt sick, and the limb became instantly locked and intensely painful, if any weight was thrown upon it. On examination, the thigh was found flexed, abducted, and rotated outwards; movement at once produced painful spasmodic contractions of the muscles, and there was excessive pain on pressure over the sciatic notch. He was put under gas, and the limb was gently carried through its complete range of flexion, extension, abduction, adduction, and rotation. Directly afterwards, though nothing seemed to give way, or to slip, he lost his pain, and he could freely move his limb. He has had no relapse.

Mr. Marsh remarked that he had brought the subject of bone-setting forward because, undoubtedly, there were a numerous set of cases which forcible movement could speedily cure, but which had not hitherto been treated as commonly as was desirable by this means. These cases, as they made but little progress under the routine treatment of rest, liniments, and elastic stockings, frequently fell into the hands of bone-setters, by whose manipulations many of them were cured. He alluded principally to cases in which adhesions had formed in or around joints, otherwise sound, as the result of injury or inflammation. Sir James Paget was the first to draw attention to this subject in a clinical lecture given as long ago as 1867, and since published in the first and second editions of his "Clinical Essays and Lectures." In this essay the principles of forcible movement as a means of treatment were very clearly and most fully laid down, and were rendered all the more distinct by being brought into contrast with those which regulate the use of perfect rest so essential for joints which were the seat of inflammation, especially of strumous disease. Displacements of cartilages and slipped tendons might be, and doubtless sometimes were, put right by bone-setters; but he believed the cases of adhesions—especially such as occurred after an injury outside a joint, which itself was healthy—afforded by far the most numerous instances of improvement after forcible movement, and he expressed his conviction that they were much more frequent in practice than many had supposed.

After referring to the classes mentioned by Dr. Hood in his lectures, the author stated that all he had observed led him fully to accord with the teaching of Sir James Paget, that when joints after injury have remained stiff, "weak," and painful, and yet free from abnormal heat, beyond the usual period of convalescence, and when they had no history of previous disease, and when a careful examination could detect no evidence of any of the diatheses, such as struma, or severe gout or rheumatism, the patient should be put under gas, and the limb should be carried in all directions through its full range of movement. As to the movement of particular joints, the author had seen good results in the shoulder, the finger joints, the knee, and the ankle. He had not used the method in either the elbow or the hip, having met with no cases which seemed suitable for it. In conclusion, he stated that, if synovitis had been present, movement must be very cautiously employed. In two knee cases lately under observation, in which synovitis had subsided for eight or nine weeks, and the joints had become perfectly free from swelling and abnormal heat, a renewed attack of inflammation, with heat, pain, and considerable effusion, had followed the manipulative treatment.

Mr. HULKE said they were much indebted to Mr. Marsh for bringing this very interesting subject before the Society. It was an opprobrium to surgery that so many people sought advice from bone-setters, not that patients could be prevented from sliding away, but because it was notorious that these empirics were or are in the habit of extracting written guarantees from their patients before proceeding to interfere with them; and thus the bone-setter, having shielded himself from the possible event of malpraxis, promises everything. To show how even intelligent people are blinded by the statements of these men, Mr. Hulke mentioned that he was consulted by a lady who had an enlarged bursa over the ischial tuberosity—a stiff hip-joint compelling her always to sit sideways on her chair. He explained the nature of the case, but the patient was persuaded to go to a bone-setter, who, after giving her oils for inunction, proceeded to put the "bone" in, which he did so effectually that the patient's husband declares that he "saw it go in!" He had no doubt some of the cases treated in this way were instances of adhesions, as Mr. Marsh had said, and the occurrence of such adhesions was long ago pointed out by Bonnet of Lyons. He (Mr. Hulke) had been personally the subject of such a condition. When in the Levant he fell over some rocks and injured his knee, which became acutely inflamed. The acute attack passed away, and left him with a stiff joint, so that he could not walk without support. Falling one day, his knee was bent under him, and, as he supposed, the adhesions must have given way, for on rising he found that he had regained free use of the joint, and could walk well without his supports; so that he thought there were such cases, which admitted of rapid cure when there was no actual disease of the joint. But, he added, we hear only of the benefit done by "bone-setting;" its disasters are carefully concealed. He had seen such disasters—often very grave mischief indeed; and more than once he had to excise a joint damaged from the rough usage it had suffered. One case he knew of, where there was disease of the shoulder and sinuses around the joint; the bone-setter broke down the adhesions, rekindling the inflammation, and the result was the death of the patient. If such cases could be published in their bare truth, the law would hardly shield the author from libel.

Mr. JOHN WOOD said there were cases in which the adhesions were outside the joint, especially the shoulder. A blow or injury on the deltoid was apt to be followed by great pain, lasting for months or even years. In such cases forcible movement was most successful, and the interpretation was that the subdeltoid bursa was inflamed and adherent to the muscle—a condition he had often found on dissection. Such cases were cured by manipulating the limb in different directions, or by acupuncture. But occasionally, after temporary relief, the pain returns. Where the articular cartilages are the seat of adhesions, such manipulative treatment was less likely to be permanently successful. Some of the cases of so-called misplacement of tendons were, he thought, really instances of inflammations of the sheaths of the tendons. The case which Mr. Marsh thought was one of displacement of the obturator tendon, was more likely an instance of effusion into the bursa in this situation; for it was difficult to see how the tendon could slip out of its groove; and the procedure adopted probably caused the rupture of the enlarged bursa. He had seen great mischief due to bone-setters, and this mainly in cases of hip-disease; and he would warn surgeons in such cases of the impropriety of attempting too early movement, lest inflammation of the bone be again set up. He had thus seen very serious symptoms started by movement attempted twelve months after the primary inflammation had subsided.

In old subjects, with tough and extensive adhesions, he had repeatedly se fracture take place from the attempt to break down adhesions. "Sudden jerks, then, were to be deprecated; but gentle and slow movements, gradually increa in range, should be the plan followed. Not long ago he saw a lady who anchylosis of both knees from rheumatism. Gentle manipulations succeeded breaking down the adhesions in one knee; but in the other (which was m firmly anchylosed) the ligamentum patellæ gave way. The smooth porcellan character of the ends of the bones, denuded of cartilage, could be felt; and in advanced a case he was sure breaking down the adhesions did but little go The ruptured ligamentum patellæ healed, but the stiffness returned to the jo There was another class of cases out of which bone-setters made much capital viz., cases of "hysterical spine"—of which he related an instance where a bo setter, pretending that the patient had twisted her spine, proceeded to mani late, and cured the patient at least for some months of the pain from which had long suffered. It was just possible, of course, that in that case one of little interspinal muscles had been displaced, and that it had been reduced manipulation; but he was inclined to think that in the majority of cases hyste was the real cause of the pain, and that the cure was attended by the decep of the patient on the one hand, and the bone-setter on the other.

Mr. T. SMITH asked whether Mr. Marsh advocated these measures for relief of stiffness in a limb following union of fractures. He was inclined believe, with Mr. Wood, that adhesions were often outside a joint, and he followed the procedure in desirable cases of the class pointed out by Sir Ja Paget, Mr. Wharton Hood, and Mr. Marsh. In six cases of Colles's fractur periods varying from six weeks to three months, where the fracture seemed have united badly, he had broken down adhesions of tendons by free and for movement. In no case had any serious disturbance followed; in two or t the manipulation was repeated more than once, and was followed up with s pooing and friction. In one case, where the whole hand was stiff, he began liberating two fingers, and then passed to the others, taking each in turn. same methods were applicable to the after-treatment of other fractures—*e. g.*, thigh and leg; in the former case the knee, and in the latter the ankle, could set free by forcible movement from the stiffness (and in the case of the ankle malposition) so often following fractures. He agreed with Mr. Wood as to improbability of one of the rotator tendons of the hip slipping out of place, its anatomical disposition hardly showed where it could slip to. But no m could he see how an interspinal muscle could be displaced.

Mr. HEATH indorsed Mr. Smith's remarks as to the after-treatment of fr tures. No fracture should be considered cured until the movement of the jo was completely restored; and, were this thoroughly appreciated, many a c would be taken out of the hands of the bone-setters. The same thing appli especially to cases of injury about the shoulder. The pain, etc., were general left to time, but in his opinion time never does cure them, and it was to regretted that some of the most eminent surgeons should take the former vie Many such cases were set right by manipulation under anæsthetics. Wheth there were adhesions inside or outside the joint was an open question. In so cases—*e. g.*, the knee—they were certainly within the joint. In breaking the down often decided loud "cracking" sound was produced, but this must n deter the surgeon. He had once fractured a humerus in this manipulation, but after union had taken place, the patient was better than before. Of course, care must be exercised in the case of old people.

Mr. BARWELL thought cases of slight subluxation, such as occurred in the shoulder and ankle, should not be overlooked. He had seen cases of injury where there were no ordinary signs of dislocation or inflammation, yet there was inability to raise the arm; and a slight manipulation under nitrous oxide would often put them right, so that in many cases the use of the arm was immediately regained. The same held good with the ankle and tarsus, where a condition of slight downward luxation of the scaphoid produced lameness and inability to bear the weight of the body on the foot. He thought there was also a condition of subluxation of the os calcis on the astragalus. He had met with displaced tendons about the malleoli, especially the peroneus longus tendon; although the tendon could be replaced, it was almost impossible to keep it in position. He mentioned an instance where a lameness was cured by manipulation, which reduced a tendon so misplaced; but in another case no device succeeded in keeping the tendon in its groove. He asked what was meant by adhesions within a joint. He had never seen on dissection any adhesions comparable to those of other serous membranes; but hypertrophied synovial fringes might become united, and he had seen union between two cartilages on the knee. He concluded by relating how a lady who was thrown down by a cab, and seen by a bone-setter, who declared a "bone was out," and after manipulation said she was cured. But the reverse was the case, for in addition to a dislocation of the hip, she had also a fracture of the neck of the thigh, probably produced by the manipulation referred to.

Mr. G. BROWN, referring to cases of anchylosis after acute rheumatism, said that owing to wasting of the muscles from impossibility of having early recourse to movement, the patient was unable to move the joint, although this may have been set free by passive motion. What procedure should be adopted in such cases, of which he had recently had an example under his care?

Mr. MORRIS said the debate suggested that it was not well to draw too much distinction between adhesions formed outside or inside a joint; but there were cases—*e. g.*, in shoulder and knee—where the contraction was due to changes in the capsule of the joint itself. He had dissected a contracted knee-joint, which could not be straightened until after division of the posterior ligament. So, again, in the shoulder there might be contractions and adhesions in the capsular ligament itself. If such structures be ruptured in attempt at restoring the limb the relief could only be temporary. He asked whether it was justifiable within six or seven weeks of the injury to resort to passive movement for the relief of stiffness due to fracture of the olecranon or patella. A recent case had brought this to his mind. A gentleman broke his olecranon by a fall on the ice, and a second injury delayed union. At the end of six weeks he became impatient to use the arm. Mr. Morris was averse to moving the limb too early. A further opinion was sought, which was favourable to forcible flexion under chloroform. This broke down the fracture again, and set up inflammation of the joint.

Mr. PRESCOTT HEWETT, who spoke on the invitation of the President, said that no doubt the cases in which the bone-setter succeeds were of the class alluded to by Messrs. Heath and Smith—viz., a slight injury followed by some contraction about a joint. The knee was often the seat of this, where, as in Mr. Hulke's case, an acute synovitis was followed by lameness due to adhesions, which could be readily broken down by forcible movement. He had broken down adhesions in knee and ankle with great benefit; he had been less successful with the shoulder, and least of all with the elbow. He found that Sir James Paget and Mr. W. Hood were of the same opinion as to the slight results following such treatment of the elbow—which is often the seat of adhesion—especially after fractures of one or other condyles. He had practised forcible movement under chloroform to break down the adhesions found in connection with contracted toes, due to wearing short and narrow shoes, such contractions occurring often after the foot had been cramped for a very short time. Some of the ca consulting bone-setters were no doubt instances of slipped tendon; he had se this occur in the case of the biceps tendon, and in those of the peronei muscle these being difficult to maintain in proper position. No doubt great injury is times done by too forcible measures employed at too early a period. He w once present when manipulation employed to break down adhesion about t hip resulted in fracture of the thigh, and that in a powerful young officer. had seen severe inflammation follow attempts to break down adhesions of t knee-joint; and in one case pyæmia followed such an attempt made on t shoulder. The worst example he knew of the injury done by bone-setters w in the case of a young gamekeeper, whose leg became inflamed and gangreno following the manipulations of the bone-setter. The thigh had to be amputat and the patient died.

Dr. E. H. **Greenhow** expressed the hope that the discussion would bear fru not that it would prevent people going to bone-setters, but that it would ena surgeons to lay down the lines of the scientific treatment of such cases, and sh their country friends that such cases were understood and could be ration dealt with. Quite lately a friend of his, the subject of hysteria only, fell in the hands of a bone-setter. Of course, it could scarcely be expected that s geons would do all that the bone-setter proposes to do—they are more cauti than the latter, to whom the adage, "Fools rush in," etc., would well apply.

Mr. **Marsh**, in reply, said that in relieving the stiffness of a shoulder it w essential to fix the scapula, which otherwise accompanied the humerus in movements. The sudden event of the pain and lameness, and the rapidity of cure in his fourth case, made him attribute it to slipping of the obturator inte tendon over a ridge of cartilage. He agreed with Mr. Wood that the j should be slight, and he had seen cases where too much force had been used the thigh fractured. To Mr. Barwell he said that he had seen actual adhe in joints; and he agreed with Mr. Morris that contraction of the ligaments likely enough to occur in severe cases.

Nerve-Stretching.

Mr. **Bartleet**, of Birmingham, in a communication to the April number the *Birmingham Medical Review*, points out that the minor disorders of ner function are rarely associated with mortal disease, or if so associated, are ov looked in the greater malady. The morbid conditions of a combined motor a sensory nerve are accompanied by varying phenomena, and, as far as we kno there are no definite physical conditions, either of a nerve or a nerve-cent which are with any degree of certainty severally associated with the subjective objective symptoms. Hence our treatment of them is, and must be, until w know more of the subject, in the main empirical.

The author refers to a case in which, after amputation of the thigh for injur the patient suffered from very distressing and painful clonic spasm of the stum and at last died absolutely worn out. After death, the part of the anterior cru nerve in contact with the brim of the pelvis was found red and apparently in flamed. Probably it is suggested, some operation directly attacking the site the nerve-irritation would, in this case, have not only increased the patient' comfort, but would even have saved his life. The excision of the painful ne romatous swellings occasionally found in stumps is, according to the author's experience, almost invariably followed by the recurrence of such growths, and by the return of the same distressing train of symptoms. It is believed that in cases of this kind good results are much more likely to be derived from an operation on

the affected nerve in its continuity. Of the propriety of such an operation in
tanus, Mr. Bartleet is inclined to be doubtful, as, in this disease, at all events
hen traumatic, the local nerve-injury which commonly is found to exist, is very
pidly associated with the condition of so-called increased polarity of the nerve-
tres. The result desired by operating upon a nerve in its continuity, is the
rogation, temporary or permanent, of this as a carrier of motor or sensory im-
ssions. This result has been attained in at least three ways: by nerve-stretch-
g, by nerve-pinching, and lastly, by nerve-freezing. During the operation of
ve-stretching, the cellular and vascular connections of the nerve are freely
ered. Any contused or thickened areolar tissue of the nerve, if such existed,
uld probably be altered in bulk or in shape, and the different contents of the
ve-fibres are compressed and displaced. The forcible pulling from above and
low might also, it is thought, sever any small fibres of the nerve proceeding
m it to neighbouring parts, especially if such fibres existed which, from dis-
e, were either more rigid or softer than natural. In the operation of nerve-
hing, the vascular supply of the nerve and its nutrition would be but slightly
fered with, and the chief results of this proceeding would be displacement of
contents of the nerve-tubes and paralysis of its functions. Nerve freezing is
formed by exposing the nerve and freezing it with ether spray. In this ope-
n the cellular and vascular connections of the nerve are undisturbed, as also
contents of the nerve-tubes. These contents, however, are frozen, and might
me permanently injured.

r. Bartleet's personal experience applies only to nerve-stretching, and he pre-
this to the other simpler and less severe operations, for this reason; that,
e we know little of the physical causes of the objective and subjective symp-
for which such operations are performed, and little also of what it is in the
tion that does good, where relief has followed its use, it is well to perform
eration which, while more severe than some others proposed, is yet not dan-
s to life or limb, and one which seems likely to affect the nutrition of the
e more or less permanently.

hree cases are reported in which Mr. Bartleet performed the operation of
e-stretching. An ill-nourished man was hurt in his work, and had to suffer
tation through the upper third of the arm. During the healing of the
p, and for many months afterwards, this patient complained of severe pains
. The stump became very tender and tremulous. No permanent benefit
obtained from change of air, tonics, or subcutaneous injections; and about
years after the amputation the man again came under the care of Mr. Bart-
who found on examination under an anæsthetic, that the stump was a very
one, and free from cicatricial adhesions, but presented nodules, which were
ht to be neuromata. An incision was made over the brachial artery, and
or five nerve-trunks were stretched. The wound healed satisfactorily, but
patient's condition remained unaltered. It was thought that some affected
es had escaped being stretched, but there was also a strong suspicion of
gering. Another operation was afterwards performed, and three cords of
rachial plexus were well stretched. The wound had not healed at the date
e publication of this article, but according to the statement of the patient,
pain had left the stump.

e second case was that of a lad, aged 17, who had had his forearm amputated,
complained for the two years following the operation of severe pain and ex-
e tenderness, which prevented his wearing anything on the stump. At the
r angle of the stump, a neuroma was detected. An incision was made near
this, and a small nerve, probably the radial, was stretched. Unfortunately,

the nerve gave way close to the neuroma. The pain was immediately relie and up to the date of publication, many months afterwards, had not recurred.

A forgeman, aged 31, had been treated unsuccessfully during many weeks a pain in the middle of the back of the left thigh, which pain had come on denly without any known cause. Beyond the pain, which was very severe, quite incapacitated the man for work, there were no objective or subjective sy toms. The patient was easy when lying in bed, but any exertion or motio the limb caused much distress. An incision having been made with antis precautions, the sciatic nerve was exposed, lifted from its bed, and then thoro stretched, being pulled forcibly from above and from below. The wound he in five days. The man was kept in bed for ten days, and suffered no pain. happy result continued after he had been permitted to get up; and the man last seen, eighteen months after the operation, was quite well, and able wi good and strong leg to resume his laborious occupation.

Mr. Bartleet considers nerve-stretching peculiarly fitted for those irregular peculiar cases in which, being ignorant of the cause, we may the more j employ an operation of the mode of action of which we are also ignorant. would certainly, he states, employ this operation in cases of tetanus in w there seemed to be a strong probability of some nerve being torn or irritated foreign body. He would also employ it for those intractable cases of neur such as some cases of sciatica, in which no other remedial treatment has p of any use, and in which it would, he thinks, be quite justifiable to perfor operation not dangerous in itself, not likely to make the patient worse, and might, perchance, relieve the sufferer of the burden of a life-long affecti *London Med. Record*, May 15, 1880.

Nerve-Grafting.

At the recent Surgical Congress in Berlin, Herr GLUCK reported the of some observations which he had made on the transplantation of nerves. experiments had been performed on twelve common fowls, from the sciatic n of which he had removed portions three or four *centimetres* (0.12 to 0.16 long, and substituted for them portions of the sciatic nerves of rabbits. A end of eleven days, the conducting power of the nerves was found to be resto irritation of the sciatic nerve above the transplanted portion (the nerve carefully isolated) producing muscular contraction. The restoration of the ducting power occurred even when the position of the peripheral and ce ends of the transplanted nerve were reversed, the latter being fastened by su to the central end of the divided nerve in the fowl, and *vice versa*. In that the result may be successful, union of the ends of the nerves by the fir tention is indispensable. This, according both to the present and the fo researches of Herr Gluck (described in Virchow's *Archiv*, Band 72), is a regeneration, consisting in the development of ganglionic cells (neurob which, at the end of three days, have united the axis-cylinders of the ce and peripheral portions, while the change of the rows of nerve-cells into nerve-fibres sets in between the sixth and the eleventh day. Herr Gluck pressed the hope that his researches might prove to be of considerable prac value. He was able to show animals which, after the nerve-grafting, walke well as others on which suture of nerves had been practised long before; on the other hand, fowls, from whose sciatic nerves large portions had been removed, still remained lame at the end of eight weeks.—*British Med. Jour* May 1, 1880.

Midwifery and Gynæcology.

Retroversion of the Gravid Womb with Rupture of the Urinary Bladder and Death.

The patient, aged 40, had had four pregnancies, the last three years ago. She d been suffering some weeks with dysuria and dyschezia, and had consulted eral medical men. When she was brought into the gynæcological ward at lle, Dr. SCHWARZ found her in a critical condition. The abdomen was more arged than it would have been at the end of pregnancy. The legs were œde- tous. On vaginal examination, the external genitals were found to be dis- ded and œdematous. The pelvis was filled with an even round, elastic tu- ur. The vaginal portion of the uterus could not be felt. By the rectum the our was also clearly made out. The bladder was evacuated and the urine seen to be opaque, dark, and mixed with blood-corpuscles. The next day, ough but little hope was entertained of saving the patient, she was put under influence of chloroform, and an attempt made to replace the uterus. It was, ever, unsuccessful. The os uteri could only be reached by forcibly pushing finger between the tumour and the symphysis pubis. The patient died the e evening. At the necropsy, Professor Ackermann found a large quantity of ish, opaque, serous fluid in the abdomen. The stomach and small intes- were much distended by flatus. The whole large and small intestines were red by a fibrinous membrane. The bladder was distended above the pubes height of 13 centimetres, and adherent by a piece of exudation of the size of a-crown to the neighbouring small intestine. On separating this a rent was vered in the bladder about 3 centimetres (1.2 inches) in length. The uterus firmly wedged under the sacral promontory. It measured 18 centimetres inches) in length, and 15 (6 inches) in breadth. The contained embryo was e male sex, and measured 22 centimetres (8.75 inches). The pregnancy at about the fourth month and a half. Dr. Schwarz discusses the mode in h the rupture might have occurred in the bladder, but it is mere conjecture. instance, he imagines an extravasation of blood in the wall of the bladder; extravasated blood decomposes, a small abscess is formed, and perforation or ure of the vesical wall results.—*London Med. Record*, May 15, 1880, from *tralblatt für Gynakologie*, March 13, 1880.

Causes of Occasional High Temperature after Aseptic Ovariotomy.

a paper read at a recent meeting of the Metropolitan County Branch, British ical Association (*British Med. Journal*, May 1, 1880), Mr. KNOWSLEY RNTON advocated the use of the term aseptic as preferable to antiseptic, the r indicating the means used, the former the actual result of properly using n. He believed that Listerism faithfully carried out in every detail enabled surgeon to perform operations aseptically—always provided that he had asep- cases on which to operate. Comparing the results obtained in his own prac- of ovariotomy before and after the adoption of Lister's method, he found his increased success, since he began to use Listerism, was out of all propor- both to his previous improvement and to that of the leading ovariotomists here in America who did not use it. An analysis of the temperature-charts of all cases done before, and of fifty done since, the adoption of Listerism, was then en; and among the occasional causes of high temperature were shown to be ction, nervous temperament, metrostaxis from irritation of ovarian nerves, and nerve-tension from too tight ligature of the pedicle. The more serious ca were congestion of the kidneys, deranged circulation from removal of a la tumour with little hemorrhage, local peritonitis, sweat rash, and failure in perfe aseptic operation.

Medical Jurisprudence and Toxicology.

Chronic Morphinism.

In the last number of *Brain*, Dr. **OBERSTEINER**, of Vienna, gives a desc tion of the effects of the habitual use of morphia, as seen in Austria, which, v able in itself, has an especial interest in connection with discussions as to the a of narcotics which have taken place in this country lately.

Chronic morphinism is, it seems, a vice which appertains peculiarly to medical profession in Austria. Quite an incredible number of Dr. Oberstei colleagues have fallen victims to it; and he hints, not obscurely, that in his there is poetical justice in the fact that this depraved and fatal taste should most havoc amongst the class of men who, by carelessly prescribing the drug instructing in the use of the hypodermic syringe, have been mainly instrum in disseminating it.

A variety of circumstances and conditions lead up to the establishment of morphia-craving. Most frequently, some painful ailment, such as tooth periostitis, or sciatica, is the starting-point of the habit; but often some ne symptom—insomnia, for example—or vomiting is its parent. The remedy taken to allay pain, procure sleep, or tranquillize the system, is soon lov its own sake, and becomes indispensable to common comfort. Then, mental troubles often determine the earliest resort to morphia. It is take soothe anxiety or to dull grief, which it is potent to do; for certain forms of ancholia, even of high intensity, are entirely dissipated by it; and then, an attempt is made to discontinue it, the discovery is made that it has plant worse grief than that which it eradicated. One curious instance of the m of origin of the morphia-craving is narrated. It is that of a young physi who was incredulous as to the rapturous ease which a cancer patient alleged had derived from morphia, and who took one dose himself as an experim That dose sealed his fate. It was like the taste of blood to the sleuth-ho and at once awakened a ravenous appetite which he could never afterwards o come.

The quantity of the drug taken by chronic morphinists varies within limits. Dr. Obersteiner has known as little as 3 *milligrammes* (= approxim the twentieth of a grain) daily suffice, without any increase, to maintain tr quillity in a lady who, whenever she was reduced to less than this little, bec restless and sleepless. On the other hand, he has known as much as 3.5 *gram* (= approximately 54 grains) taken daily and continuously for long peri More than this quantity cannot, however, be taken by any one with impun The rule seems to be that, in most cases, more and more must be taken to k up the full influence of the drug, but that a point is ultimately reached bey which it is impossible to go. The morphinist generally finds out this point himself, and acute poisoning by morphia is an exceedingly rare occurrence amo those who are perpetually experiencing its chronic toxic effects.

The symptoms of morphinism are apparently pretty much in Austria what th are in England, and are so well known that it is unnecessary to give any detailed account of them. Most prominent among them are disinclination to exertion, loss of appetite, hyperæsthesia, frequent yawning and sneezing, a peculiar ashy grayness of complexion, impotence, and general emaciation. On the psychical ide are to be noted loss of memory, suicidal tendencies, and a moral deteriora-ion comparable to what is seen in chronic alcoholism. Falsehood, which is first ad recourse to in order to conceal or palliate the evil habit indulged in, soon ervades the whole mind, and the morphinist becomes the prolific father of lies pon all subjects, even when truth would serve as well.

The morphia-hunger, which comes on when fasting from the drug is enforced, sometimes accompanied by explosive symptoms, such as mania, dangerous im-lses (often involving the fast-compelling doctor), hallucinations of the senses, pious perspirations, and collapse. These follow alike its sudden and its gradual thdrawal, and, in the latter case, generally present themselves towards the d of the weaning period, when complete abstinence has been nearly reached. here no explosive symptoms signalize the morphia-hunger, it is expressed in lessness, sleeplessness, diarrhœa, and great debility, while the feelings that associated with it are as distressing as those which depend on starvation and rst. To relieve these feelings, wine in tolerably large amounts, the bromide potassium, and warm baths are recommended. Packing in wet sheets is also d to be of service, and the subcutaneous injection of small quantities of any id free from morphia seems to have a delusively calmative effect on the en-bled mind.

The prognosis in chronic morphinism is not, according to Dr. Obersteiner, so ourable as has been sometimes maintained. It is best when the habit has n of brief duration, and originated in some transient cause, and where the ent is of a vigorous constitution of body; it is worst when the habit has been practised, when it sprang out of some incurable condition or often recurring , and when the patient is of the nervous temperament. Morphinism is pecu-ly a neurotic vice, and it is neurotic subjects that fall into states of alarming citement or weakness when reformation is attempted. With them, readminis-tion of morphia is sometimes needful after its use had been broken off, to pre-t serious consequences, amongst which are complete disintegration of the mind abject despondency, ending in suicide. In all cases of morphinism, relapses to be apprehended, and these sometimes take place when profuse gratitude is ng expressed to the physician for his assistance in effecting a cure. Where pses have happened, it is perhaps better to be content with a diminution in the ount taken than to insist on total abstinence.

Morphinism may be of medico-legal interest. The moral imbecility which companies it may bring the individual abandoned to it into collision with the , though this is less likely to occur than in alcoholism, for the morphinist is re of a recluse than the beer-toper or spirit-drinker. The habit has not yet n admitted as a ground of irresponsibility; but, not long ago, a young man Vienna advanced it as a plea on his own behalf. He was taken in the act of king the pockets of two ladies simultaneously in a crowd; and his excuse was t, through taking morphia, his cerebral bloodvessels were congested and his eas perverted. He offered to take a *gramme* (= 15 grains) of morphia at one se, in order to prove that he was a morphinist, thus shadowing forth a new anch of experimental adjudicature. But, in course of observation by the lice-surgeon, it became clear that he could not simulate the phenomena of orphia-hunger, and he was not, therefore, submitted to the hazardous test which proposed, but was dealt with as a common thief.

A series of experiments which he performed on animals did not yield Dr. Obersteiner any very characteristic results. After injecting a number of rabbits with hydrochlorate of morphia daily, in gradually increasing doses, he observed; that a habituation to it took place in rabbits as in man; and that, after its continuous use for long periods, there occurred in these animals weakness and loss of muscular tone, most marked in the hinder extremities, and also trophic affections of the skin. A sort of *alopecia areata* was set up; the hair began to fall out, particularly on the neck, so that the skin was denuded in patches. No pe manent contraction of the pupils was noticed; the vessels of the ears wer shortly after the injection, contracted, but later became dilated. Except slightly increased reflex excitability, no effect of the sudden cessation of the use of m phia was observed in rabbits. During its administration, many of these anim died suddenly in convulsion, their brains being found swollen and œdematous.

An interesting paper on morphinism has also been published in No. 6 of th *Berliner Klinische Wochenschrift* for the present year, by Dr. E. LEVINSTEI Director of the Asylum at Schöneberg near Berlin; who, as is well known, h devoted much attention to the subject. Besides the various nervous changes a local affections (in the form of albuminuria) to which morphinists are liable, h describes a fever attending morphinism, which presents three varieties. T first, which has been described as morphia-intermittent, resembles ordinary m larial intermittent in being characterized by rigors, heat, and sweating, and g erally considerable swelling of the spleen; the type is sometimes tertian, usu quotidian, sometimes irregular; and violent delirium may occur during the feb paroxysms. In the second form, there are rigors every evening, followed b sensation of heat with moderate rise of temperature, and thirst. The third f presents typhoid phenomena; viz., headache, buzzing in the ears, vertigo, sli fever, with a temperature of 38.3° Cent. (101° Fahr.), and paresis of acc modation; the patients are confined to bed for two or three weeks.

In the treatment, Dr. Levinstein has preferred the sudden withdrawal of morphia. In order, however, to obviate the danger of collapse which att this proceeding in some specially severe cases, he has adopted a modified pl which consists in giving, twenty-four hours after the last large dose of morp has been used, a considerably smaller quantity, varying from one-thirtieth to o tenth of the former dose, and repeating it on the next two or three days; aft which, injection has rarely been found necessary.

Dr. Levinstein has had under treatment for morphinism 82 men and 28 wome Of these, 32 were medical men, 8 medical men's wives, 7 persons connected wi professional work or residing in medical practitioner's houses, 8 apothecaries, a 1 apothecary's wife. Of the 110 patients, 4 were also drunkards. Of the men, 61 had relapses, and 10 out of the 28 women; of the 32 medical men, returned to the habit, and so did all the apothecaries.

There were four deaths among the medical morphinists. Three died with th ordinary symptoms of morphia poisoning; and the fourth perished, after th treatment by withdrawal had been commenced, from secretly taking a large do of morphia which he had previously borne well.—*British Med. Journal*, May 1, 1880.

MEDICAL NEWS.

American Medical Association.—The thirty-first annual meeting of the American Medical Association was held in the city of New York on June 1st, 2d, 3d, and 4th, Dr. Lewis A. Sayre, of New York, President, in the chair.

June 1st. The convention was called to order at 11 A. M., and, after prayer, an address of cordial welcome was delivered by Dr. T. Gaillard Thomas, Chairman of the Committee of Arrangements.

The Secretary read the list of names registered up to that time, 372 in number, which on motion was confirmed.

Protests were entered against the admission of delegates from the United States Navy, and against certain delegates from Allegheny County, which were referred to the Judicial Council.

Dr. Sayre then delivered the President's Address, which had for its text the celebrated apothegm of Sydney Smith, which served for the motto of the early numbers of the *Philadelphia Journal of the Medical and Physical Sciences.* "In the four quarters of the globe, who reads an American book? or goes to an American play? or looks upon an American picture or statue? What does the world yet owe to American physicians or surgeons?" The address closed with an advocacy of the abolition of the annual volume of Transactions and the substitution of a weekly medical journal to be published by the Association.

On motion of Dr. Brodie, of Michigan, the thanks of the Association were tendered to the President for his Address, and the Chair was directed to appoint a committee of five to report upon the recommendations which it contained. The President appointed as the committee, Drs. Chaillé, of La., S. D. Gross, of Phila., J. S. Weatherley, of Ala., J. R. Bronson, of Mass., and W. R. Gillette, of New York.

Dr. S. D. Gross, of Phila., moved that the Association tender to its President, and, through him, to the family, its warmest sympathy in their sad bereavement by the death of Dr. Charles H. H. Sayre. Adopted.

Dr. E. Seguin, of New York, presented the report of the foreign delegation on the progress of medical international uniformity.

Dr. Austin Flint, Chairman of the Committee on Prize Essays, reported that the Committee did not feel warranted in awarding a prize to the single essay presented.

June 2d. Dr. A. L. Gihon, U. S. N., brought up the question of the admission of the delegation from the U. S. Navy, which provoked considerable discussion. Dr. S. D. Gross, of Phila., moved that, as the Judicial Council stated that no charges preferred against the delegation from the U. S. Navy had been authenticated, the delegation be admitted. Carried.

Dr. Benham, of Penna., of the Judicial Council, reported concerning the matter of the Allen County Medical Society, Indiana, referring the questions to the State Medical Society for adjudication.

The Committee on Nominations was then announced.

Dr. Pratt, of Mich., reported from the Committee appointed last year to consider the propositions submitted by Dr. Chaillé, of La. (see Trans. Am. Med. Assoc., 1879, p. 51), adversely to all the propositions except the fourth, which contemplated substituting a medical journal for the present volume of Transactions. On that proposition the Committee expressed the opinion that it was safer to await the law of growth than to adopt any radical change at present.

Dr. J. S. Lynch, of Baltimore, Chairman of the Section on the Practice of Medicine, then delivered his address, which was followed by that of Dr. W. T. Briggs, of Nashville, Chairman of the Section on Surgery and Anatomy.

The Association then adopted the following amendment in reference to Prize Essays and the Committee on Prize Essays, as an addition to Section II. of the By-laws.

a. There shall be four annual prizes of two hundred and fifty dollars each, which shall be awarded at the close of the second year after announcement, as hereinafter explained, for strictly original contributions to medical and surgical progress.

b. It shall be the duty of the Chairman of each of the following four Sections: 1. Practical Medicine, Materia Medica, and Physiology; 2. Obstetrics and Diseases of Women and Children; 3. Surgery and Anatomy; 4. State Medicine and Public Hygiene, to appoint annually, before the adjournment of the meeting of the Association, three members of ability and good judgment who shall constitute a Committee of Selection, and who shall, within thirty days thereafter, select and publicly announce for competitive investigation and report, a subject belonging to one or other of the branches of medicine included in the title of the Section.

c. It shall also be the duty of the Chairman of each of the Sections mentioned to appoint annually a Committee of Award, consisting of three experts, who shall carefully examine the essays offered for competitive examination, and if any one shall be found worthy of the prize as a substantial contribution to medical knowledge, to recommend the same to the Association.

d. All essays placed by their authors for competition shall be in the hands of the Chairman of the respective Committees of Award on or before the first day of January preceding the meeting of the Association at which the reports of the committee are required to be made.

e. All Prize Essays shall be considered as the property of the Association.

f. The names of the authors of the competing essays shall be kept secret from the committees by such means as the latter may provide.

g. Membership in either of the two committees shall not debar from membership in the other; nor shall membership in the Committee of Selection exclude a member from the privilege of offering a competing essay.

June 3d. Dr. W. O. Baldwin, of Ala., Chairman of the Committee on Nominations, presented the following report: *President,* John T. Hodgen, M.D., of St. Louis. *Vice-Presidents,* Drs. W. H. Anderson, of Ala., Levi G. Hill, of New Hampshire, Henry T. Holton, of Vermont, and H. Carpenter, of Oregon. *Permanent Secretary,* Dr. W. B. Atkinson, of Penna. *Treasurer,* R. J. Dunglison, M.D., of Penna. *Librarian,* Wm. Lee, M.D., of D. C.

Chairman of Section on Practice of Medicine, Dr. Charles Denison, of Colorado. *On Surgery,* Dr. Hunter McGuire, of Virginia. *On Obstetrics,* Dr. Jas. R. Chadwick, of Mass. *On Medical Jurisprudence,* Dr. J. T. Reeve, of Wis. *On Ophthalmology,* Dr. D. S. Reynolds, of Ky.

Members of Judicial Council, Drs. J. K. Bartlett, of Wis., F. Staples, of Minn., D. R. Wallace, of Texas, J. G. Thomas, of Ga., J. S. Billings, of U.S.A., J. H. Warren, of Mass., and A. T. Woodward, of Vt.

The Committee recommended that the next meeting be held in Richmond, Va., on the first Tuesday in May, 1881. The report was unanimously adopted.

Dr. Chas. Denison, of Col., offered his resignation as Chairman of Section on Practice of Medicine, which was adopted and referred to the Committee on Nominations.

Dr. Bronson, of Mass., offered the following preamble and resolution, which were adopted.

Whereas, The published proceedings of various sections of the Association do not receive the practical expression desired, and do not represent the labours of its members: and whereas, the members of the Association have long felt that the present mode of introducing the Transactions to the profession has been unsatisfactory to all concerned in the advancement of medical science; therefore be it

Resolved, That a committee of five be appointed by the Chair to report at the next session regarding the practicability of formulating all the proceedings in journalistic form, as recommended by the President in his Annual Address.

Under this resolution the President appointed the following Committee: Drs. W. W. Dawson, of Ohio, J. R. Bronson, of Mass., W. H. Pancoast, of Penna., N. C. Husted, of N. Y., and J. S. Green, of N. J.

Dr. J. S. Billings, of U. S. A., reported that Congress had made provisions for the publication of the Catalogue of the Library of the Surgeon-General's Office, of which the first volume would be published in July, 1880, and the second probably in July, 1881.

The following amendments to the Constitution, proposed by Dr. J. H. Rauch, of Illinois, were adopted: Article II., second paragraph, after "Army and Navy" insert, "and the Marine-Hospital service of the United States." Fourth paragraph, at the end, insert, "The Marine-Hospital service of the United States shall be entitled to one delegate."

Dr. S. C. Busey, of D. C., offered an amendment to the By-laws, making provision for a new section to be designated Section VI., Diseases of Children. Adopted and referred to the Committee on Nominations.

The Metric Executive Committee presented a report.

The Judicial Council presented the following:—

Whereas, A protest without signature, against the registration of the delegates from the Medical Staff of the U. S. Navy, and unaccompanied by charges, had been placed in the hands of the Judicial Council, therefore be it

Resolved, That the protest against the registration of delegates from the Medical Department of the United States Navy is not sustained, and therefore there was no cause for action thereon. Adopted.

Resolved, That the Hannibal Medical Society of Missouri is not entitled to representation in the American Medical Association, because it is not in affiliation with its own State Medical Society. The protest therefore was sustained.

Dr. James F. Hibberd, of Ind., Chairman of the Section on Medical Jurisprudence, then delivered his address.

Dr. J. M. Toner, of Washington, D. C., presented the report of the Committee on Necrology.

The President announced the following appointments: Delegates to the Canada Medical Association, Drs. C. N. Bush, of New York; James R. Leaming, of New York; D. H. Goodwillie, of New York; Wm. Brodie, of Michigan; and W. B. Ulrich, of Pennsylvania. Delegates to European Medical Societies, Drs. R. B. Cole, of California; Benj. Lee, of Pennsylvania; M. A. Pallen, of New York; and L. D. Bulkley, of New York.

The report of the Librarian was then read. The library contains 3258 volumes, and $200 was voted to defray its expenses.

June 4. A communication from Dr. F. Horner, Jr., inclosing a resolution of the State Medical Society of Virginia, instructing its delegation to ask the Association to take the necessary steps for establishing a mutual aid association was received and referred.

A communication from the Philadelphia County Medical Society, concerning the abuse of medical charities, was received and referred to a special committee appointed by the chair as follows: Drs. Benj. Lee, of Pennsylvania; H. G. Piffard, of New York; S. W. Gross, of Pennsylvania; and J. W. Green.

Dr. A. L. Carroll, of New York, offered the following:—

Whereas, The New York County Medical Society has admitted to membership graduates of schools not recognized by this Association, therefore be it

Resolved, That societies which admit irregular practitioners to membership be debarred from representation in the American Medical Association. Referred to the Judicial Council.

The Treasurer's report was then read, and shows receipts of $5025, and a balance on hand of $579.59.

The Committee on Publication presented a report.

Dr. Pratt, of Michigan, moved a resolution instructing the Committee of Arrangements to publish one programme of the work to be done in general session at the next annual meeting during the whole four days, instead of a daily programme. Adopted.

The Committee on Nominations presented the following additional report: *Assistant Secretary*, Dr. J. G. Cabell, of Virginia. *Committee of Arrangements*, Drs. F. D. Cunningham, Hunter McGuire, and Cullen, of Richmond, Va., with power to enlarge their number to seven. *Committee of Publication*, Drs. W. B. Atkinson, T. M. Drysdale, Wm. Lee, R. J. Dunglison, Alfred Fricke, S. D. Gross, and Caspar Wister. *Chairman of Section on Practice of Medicine*, Dr. William Pepper, of Pennsylvania. *Chairman of Section on Diseases of Children*, Dr. A. Jacobi, of New York.

Dr. H. G. Piffard, of New York, moved that the Richmond County (N. Y.) Medical Society, which has members who have been irregular practitioners of medicine, be debarred from representation in the American Medical Association. Referred to the Judicial Council.

Dr. Brodie, of Michigan, then offered the usual resolutions of thanks.

On motion of Dr. Marcy, of Massachusetts, a donation of $1000 out of the funds of the Association was granted to Dr. Wm. B. Atkinson, the Permanent Secretary.

Dr. J. F. Hibberd, of Indiana, Chairman of the Section on Medical Jurisprudence and State Medicine, offered resolutions endorsing the National Board of Health; recommending Medical schools to establish a Chair of State Medicine as part of the regular curriculum; and that the name of the Section shall be hereafter "Section on State Medicine." Adopted.

Dr. John S. Hodgen, of St. Louis, President-elect, was then introduced to the Association.

A vote of thanks to Dr. Sayre for the ability and courtesy with which he had presided over the meetings was passed, and, after a suitable response by Dr. Sayre, the Association adjourned, to meet at Richmond, Va., on the first Tuesday in May, 1881.

—

American Laryngological Society.—The second annual meeting of this Society was held in New York, May 31st and June 1st and 2d. In the absence from the country of the President, Dr. Elsberg, Dr. J. Solis Cohen, of Philadelphia, was called to the chair. A number of interesting papers were read and intelligently discussed. The following officers were elected for the ensuing year: President, Dr. J. Solis Cohen, of Phila.; Vice-Presidents, Dr. W. C. Glasgow, of St. Louis, and J. D. Roe, of Rochester; Secretary and Treasurer, Dr. G. M. Lefferts, of New York. The next meeting will be held in Philadelphia in 1881.

—

Association of American Medical Editors met in New York May 31st, Vice-President Dr. Frank Woodbury, of Phila., Assistant Editor of *Boston Medical* *and Surgical Journal*, presiding, in the absence of Dr. Powell, of Atlanta. The following officers were elected for the ensuing year: President, Dr. Geo. F. Shrady, of *Medical Record;* Vice-President, Dr. R. S. Nelson, of the *St. Louis Courier of Medicine;* Secretary, Dr. D. S. Reynolds, of the Louisville *Medical Herald.*

—

Connecticut Medical Society met in eighty-ninth annual convention, at New Haven, May 26th and 27th, Dr. A. R. Goodrich, President, in the chair. The following office-bearers were elected for the ensuing year: President, G. L. Platt, of Waterbury; Vice-President, M. Deming, of Litchfield; Secretary, C. W. Chamberlain, of Hartford.

—

Georgia Medical Association held its annual meeting at Augusta on the 21st of April, Prof. Joseph Eve, President, in the chair. The following officers were elected for the ensuing year: President, J. C. Le Hardy, M.D., of Savannah; Vice-Presidents, Drs. E. W. Alfriend, of Albany, and W. B. Wells, of Red Clay; Secretary, Dr. James B. Baird, of Atlanta.

—

Massachusetts Medical Society.—The ninety-ninth annual meeting of this Society was held at Boston June 9th, President, Dr. George H. Lyman, of Boston, in the chair. The following officers were elected for the ensuing centennial year: President, Dr. Henry W. Williams, of Boston; Vice-President, Dr. Asa Millett, of Bridgewater; Orator, Dr. J. Collins Warren, of Boston; Anniversary Chairman, Dr. James C. White, of Boston. The ensuing centennial meeting will be held in Boston on the second Wednesday in June, 1881.

—

Michigan State Medical Society.—The fifteenth annual meeting of this Society was held at Grand Rapids May 12th, Dr. George K. Johnson, of Grand Rapids, President, in the chair. A number of interesting papers were read, and the Society evinced its interest in the efforts to advance the standard of medical education by the adoption of the following preamble and resolution:—

Whereas, The State Medical Society of Michigan views with gratification the evidences that its labours for a more elevated standard of medical education have not been without reward, in the fact that all the medical schools of the State have made a preliminary examination and a three-term graded course a requisite for graduation; therefore

Resolved, That we, the members of the State Medical Society, pledge ourselves, individually and collectively, to support only such schools as require for admission a thorough preliminary examination, and for graduation at least a three-term graded course of lectures in three years of study; and that we will use our influence to prevent students from attending any college with an inferiority of preparation and graduation.

The following officers were elected for the ensuing year: President, J. R. Thomas, M.D., of Bay City; Vice-Presidents, Drs. E. P. Christian, of Wyandotte; J. W. Hagadorn, of Milford; C. J. Lundy, of Detroit; J. H. Bennett, of Coldwater; Secretary, G. E. Ranney, of Lansing. The next meeting will be held at Bay City on the second Wednesday in June, 1881.

—

Medical Society of North Carolina.—The twenty-seventh annual meeting of this Society was held at Wilmington, May 11th, 12th, and 13th, Dr. J. F. Shaffner, of Salem, President, in the chair. The following office-bearers were elected for the ensuing year: President, Dr. Richard B. Haywood, of Raleigh; Vice-Presidents, Drs. J. A. McRae, of Fayettesville; W. H. Lilly, of Concord; R. H. Speight, of Tarborough; and W. J. H. Bellamy, of Wilmington; Secretary, Dr. D. L. Julian Picöt, of Littleton.

The Pennsylvania State Medical Society held its thirty-first annual meeting at Altoona, May 19th, 20th, and 21st, Dr. Andrew Nebinger, of Phila., President, in the chair. Dr. J. L. Carpenter, of Pottsville, delivered the address in Obstetrics; Dr. J. H. Packard, of Phila., the address in Surgery; Dr. I. N. Kerlin, of Del. Co., the address in Mental Disorders; and Dr. Benj. Lee, of Phila., the address in Hygiene. The following officers were elected for th ensuing year: President, Dr. J. L. Carpenter, of Schuylkill County; Vice-Presidents, Drs. Thomas Lyon, of Lycoming; William Varian, of Crawford; C. A. Rahter, of Dauphin; and M. R. Cowden, of Butler; Recording Secretary, Alexander Craig, of Lancaster. The next meeting will be held at Lancaster on the second Wednesday of May, 1881.

—

American Ophthalmological Society will hold its annual meeting at Newport on the 22d of July.

—

International Otological Congress.—The second International Otologic Congress will be held at Milan, Italy, from Sept. 6th to 9th, of this year. Pro Voltolini, of Breslau, is President of the Committee of Arrangements.

—

British Medical Association.—The forty-eighth annual meeting of the Britis Medical Association will be held at Cambridge, August 13, 1880, under th presidency of Dr. G. M. Humphry, Professor of Anatomy in the University o Cambridge. The address in Medicine will be delivered by Dr. J. B. Bradbury; the address in Surgery by Mr. Timothy Holmes; and the address in Physiolog by Dr. Michael Foster.

—

New York State Board of Health.—This Board has just been organize under a law passed by the last Legislature, by the election of Dr. E. M. Mo of Rochester, President, and Dr. Elisha Harris, of New York, Secretary.

—

Death under Bromide of Ethyl.—A case of this occurred on the 26th of May in the clinic of Dr. Levis at the Jefferson College Hospital in this city. The patient was eighteen years of age, and had a vesical calculus; he was greatly prostrated; and suddenly died after inhaling about a drachm of the anæsthetic, and after the first incision in the operation of lithotomy had been made. Artificial respiration was unavailing. Upon post-mortem examination the brain, heart, lungs, and kidneys were reported to have been greatly diseased.

—

Literary Notes.

D. Appleton & Co. announce "a Practical Treatise on Tumours of the Mammary Gland," by Dr. S. W. Gross, and have in preparation a work on the "Science and Art of Midwifery," by Dr. Wm. T. Lusk, of New York; a "Treatise on Insanity," by Dr. Wm. A. Hammond, and a translation of Fournier's "Syphilis and Marriage."

Smith, Elder, & Co., of London, have just published a small volume on "Antiseptic Surgery," by Mr. MacCormac, of St. Thomas's Hospital.

J. & A. Churchill have also published Morell Mackenzie's "Manual of Diseases of the Throat and Nose. Vol. I., Diseases of Pharynx, Larynx, and Trachea," and have in press a volume "On Chronic Atrophy of the Stomach, and on Nervous Disorders of the Digestive Organs," by Dr. Samuel Fenwick, Assist. Phys. to the London Hospital. They also announce that Dr. Thomas Buzzard is preparing for publication some "Clinical Lectures on Diseases of the Spinal Cord."

Dr. Thomas Radford, of Manchester, is engaged on a second edition of his "Record of Cæsarean Sections in Great Britain."

SMITH ON CHILDREN—New Edition—Now Ready.

COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. By J. Lewis Smith, M.D., Clinical Professor of Diseases of Children in the Bellevue Hospital Medical College, New York. Fourth edition, revised and enlarged. In one handsome octavo volume of over 750 pages, with illustrations. Cloth, $4 50; leather, $5 50; very handsome half Russia, $6.

e treatise by Dr. J. Lewis Smith is one which obtained a well-deserved reputation, not only merica but also in this country. Consisting of losely printed pages, Dr. Smith's volume con- much excellent teaching on the various sub- discussed. The author has had a very large rience in the treatment of infantile diseases, renders his work a most useful one for the ical purposes of all who are engaged in the ment of the affections of infancy and child- In this new edition the sections on thera- s have received special attention in the revisal. volume is also supplied with a copious and able index.—*London Med. Times and Gaz.*, 1879.

the period which has elapsed since the third s of the work, so extensive have been the ad- that whole chapters required to be rewritten, ardly a page could pass without some material ion or addition. This labor has occupied the closely, and he has performed it conscien- so that the book may be considered a faithful portraiture of an exceptionally wide clinical experience in infantile diseases, corrected by a careful study of the recent literature of the subject.—*Med. and Surg. Reporter*, April 5, 1879.

The author has evidently determined that it shall not lose ground in the esteem of the profession for want of the latest knowledge on that important department of medicine. He has accordingly incorporated in the present edition the useful and practical results of the latest study and experience, both American and foreign, especially those bearing on therapeutics. Altogether the book has been greatly improved, while it has not been greatly increased in size.—*N. Y. Journ. Med.*, June, 1879.

Having so recently expressed our favorable opinion of the third edition of Dr. J. Lewis Smith's treatise, his second edition having been also reviewed in like terms of commendation three years previously, little remains to be said in praise of this, the fourth edition, of so valuable and practical a work.—*Dub. Journ. of Med. Sci.*, Nov. 1879.

HABERSHON ON THE ALIMENTARY CANAL—New Edition—Now Ready.

THE DISEASES OF THE ABDOMEN, COMPRISING THOSE OF THE STOMACH, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines, and Peritoneum. By S. O. Habershon, M.D., Senior Physician to and late Lecturer on the Principles and Practice of Medicine at Guy's Hospital, etc. Second American, from the third enlarged and revised English edition. With illustrations. In one handsome octavo volume of over 00 pages. Cloth, $3 50.

valuable treatise on diseases of the stomach domen has been out of print for several years, therefore not so well known to the profession serves to be. It will be found a cyclopædia rmation, systematically arranged, on all dis- of the alimentary tract, from the mouth to the A fair proportion of each chapter is devoted mptoms, pathology, and therapeutics. The edition is fuller than former ones in many lars, and has been thoroughly revised and ed by the author. Several new chapters have dded, bringing the work fully up to the times, aking it a volume of interest to the practi- in every field of medicine and surgery. Per- nutrition is in some form associated with all diseases we have to combat, and we need all the light that can be obtained on a subject so broad and general. Dr. Habershon's work is one that every practitioner should read and study for himself.—*N. Y. Med. Journ.*, April, 1879.

The first edition was esteemed the best publication of the kind in the language, and was a boon to the young practitioner. The present edition, while retaining all the essential features of the first, has been enriched by the fruits of twenty years of experience and observation of its author. Habershon's is an excellent book, and may be commended to every student and practitioner.—*Am. Practitioner*, July, 1879.

DUNCAN'S CLINICAL LECTURES ON DISEASES OF WOMEN—Just Ready.

ICAL LECTURES ON THE DISEASES OF WOMEN. Delivered in St. Bartholomew's Hospital. By J. Matthews Duncan, M.D., LL.D., F.R.S.E., etc. In one very neat octavo volume of 175 pages; cloth, $1 50.

e lectures are what might have been antici- from one so highly esteemed as a writer and er. As a general gynæcologist, Dr. Duncan ew equals, and no superior; and his book is bodiment of his thoughts and observations, ely and carefully set forth, and upon a variety jects. We heartily recommend the work to American practitioner as a valuable guide for —*Am. Journ. of Med. Sci.*, April, 1880.

is an unpretentious book of small dimen- , but full of value in inverse proportion to its These lectures should be read by every one practises and studies the diseases of women.— *da Med. and Surg. Journ.*, May, 1880.

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journal*, March, 1880.

ROBERTS ON RENAL DISEASES—New Edition—Just Ready.

PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, INCLUDING URINARY DEPOSITS. By William Roberts, M.D., Lecturer on Medicine in the Manchester School of Medicine, etc. Illustrated by numerous cases and engravings. Third American, from the third revised and enlarged English edition. In one handsome octavo volume of over 600 pages. Cloth, $4.

. Roberts's treatise continues to be a most val- e guide to the students of clinical medicine.— *n Med. and Surg. Journ.*, March 26, 1880.

he reputation of Dr. Roberts as an authority in department, and the lucid style in which the work is written, will secure for this treatise a wide circulation among American physicians and students.—*Cincinnati Lancet and Clinic*, March 20, 1880.

HENRY C. LEA'S SON & CO.—Philadelphia.

NOTICE TO SUBSCRIBERS.

INCREASED INDUCEMENTS FOR 1880.

With a view of increasing the attractions of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," and of bringing within the reach of all members of the profession the immense amount of information now presented by it and its accessory periodicals, the "MEDICAL NEWS AND LIBRARY" and the "MONTHLY ABSTRACT," the two latter will hereafter be merged together, under the name of "THE MEDICAL NEWS AND ABSTRACT," commencing January 1, 1880. The "NEWS AND ABSTRACT" will consist of sixty-four pages per month, handsomely printed, in a neat cover, and will contain all the material heretofore presented in both periodicals, with the exception of the sixteen pages of the "Library Department." Its price will be TWO DOLLARS AND A HALF per annum, invariably in advance, at which rate subscribers will receive nearly *eight hundred large octavo pages per annum*, free of postage.

Not only will this monthly thus be in itself one of the cheapest periodicals offered to the profession, but it will be furnished in commutation, without charge, to advance-paying subscribers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," the subscription to which will remain, as heretofore, FIVE DOLLARS per annum. For this very moderate sum, therefore, subscribers will receive two periodicals of the highest class, a Quarterly and a Monthly, containing in all nearly two thousand pages per annum, stored with the choicest original and selected matter that can be furnished by the medical literature of both hemispheres.

These terms may be recapitulated as follows:—

TERMS FOR 1880.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance.	Five Dollars.

The MEDICAL NEWS AND ABSTRACT, invariably in advance, Two Dollars and a Half.

⁂ Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

It is evident that only a very considerable increase to the existing subscription list will justify the unexampled terms thus offered, by which the equivalent of three or four large octavo volumes is furnished, handsomely printed in a form for preservation, for the trifling sum of FIVE DOLLARS. Gentlemen, therefore, are respectfully requested to lose no time in remitting their subscriptions to avoid the risk of disappointment from the exhaustion of the edition printed; and it is suggested that they may aid in rendering the enterprise permanent by kindly communicating to their friends the very great inducements thus offered.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

of the Librarian of Congress. All rights reserved.

NEW MEDICAL BOOKS—In Press.

BARTHOLOW'S MEDICAL ELECTRICITY.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATIONS TO MEDIC
By ROBERTS BARTHOLOW, A.M., M D., LL.D., Professor of Materia Medica and G
Therapeutics in the Jefferson Medical College of Philada. In one very handsome
volume of about 450 pages, with illustrations.

The constantly increasing therapeutic use of electricity, and the absence of a concise guide sui
wants of the general practitioner, have induced the author to prepare the present volume. Ea
has been to present the most advanced state of existing knowledge in a form divested of
technicalities, keeping constantly in view the practical needs of the student and physician.
As the volume is founded upon a course of lectures delivered in the Jefferson Medical Colleg
the spring of 1880, its adaptation to its purpose is insured. Dr. Bartholow's power of lucid exp
well known, and is particularly desirable in a subject such as this, treated from the standpoi
general practitioner and not of the specialist.

RICHARDSON'S PREVENTIVE MEDICINE.

PREVENTIVE MEDICINE. By BENJAMIN RICHARDSON, M. D , F. R. S., M. A., LL. D.,
Fellow of the Royal College of Physicians, London. In one octavo volume of ab
pages.

The immense strides taken by medical science during the last quarter of a century have had
conspicuous field of progress than the causation of disease. Not only has this led to marked ad
therapeutics, but it has given rise to a virtually new department of medicine—the prevention of
more important, perhaps, in its ultimate results than even the investigation of curative proce
thus far there has been no attempt to gather into a systematic and intelligible shape the acc
of knowledge thus far acquired on this most interesting subject. Fortunately, the task has bee
undertaken by a writer who of all others is perhaps best qualified for its performance, and the
his labors can hardly fail to mark an epoch in the history of medical science. The plan adopte
execution of this novel design can best be explained in his own words:—

"With the object here expressed I write this volume. I have nothing to say in it that has any
to the cure of disease, but I base it nevertheless on the curative side of medical learning. In oth
I trace the diseases from their actual representation as they exist before us, in their natural prog
their birth, as far as I am able, back to their origins, and try to seek the conditions out of w
spring. Thereupon I endeavor further to analyze those conditions, to see how far they are r
and how far they are avoidable."

THOMAS ON WOMEN—New and Revised Edition.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. GAILLARD
M.D., Prof. of Obstetrics etc., in the College of Physicians and Surgeons, New Yor
Edition, thoroughly revised and rewritten. In one large and handsome octavo v
over 850 pages, with about 270 illustrations.

The author has taken advantage of the opportunity afforded by the call for a new edition of
to render it worthy a continuance of the very remarkable favor with which it has been recei
portion of the work has been carefully revised, very much of it has been rewritten, and ad
alterations introduced wherever the advance of science and the increased experience of the a
shown them desirable. At the same time special care has been exercised to avoid undue inc
size of the volume. To accommodate the numerous additions a more condensed but very clea
been used, notwithstanding which, the number of pages has been increased by more than fifty.
of illustrations has been extensively changed; many which seemed to be superfluous have bee
and a large number of new and superior drawings have been inserted. In its improved form,
it is hoped that the volume will maintain the character it has acquired of a standard authority
detail of its important subject.

WELLS ON THE EYE—New Edition.

A TREATISE ON DISEASES OF THE EYE. By J. SOELBERG WELLS, late Pr
Ophthalmology in King's College Hospital. Third American, from the Third Eng
tion. Thoroughly Revised, with copious Notes and Additions, by CHARLES S. Bu
Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated
250 Engravings on Wood and six Colored Plates, together with selections from the
of Jaeger and Snellen. In one large and very handsome octavo volume of nine h

The long-continued illness of the author, with its fatal termination, has kept this work for
out of print, and has deprived it of the advantage of the revision which he sought to give it
last years of his life. This edition has therefore been placed under the editorial supervision of
who has labored earnestly to introduce in it all the advances which observation and exper
acquired for the theory and practice of ophthalmology since the appearance of the last revis
complish this, considerable additions have been required, and the work is now presented in the
that it will fully deserve a continuance of the very marked favor with which it has hitherto be
as a complete, but concise, exposition of the principles and facts of its important department
science. The additions made in the previous American editions by Dr. Hays have been retained,
the very full series of illustrations and the test-types of Jaeger and Snellen.

FOTHERGILL'S HANDBOOK OF TREATMENT—New Edition.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; OR, THE PRINCIPLES OF
PEUTICS. By J. MILNER FOTHERGILL, M.D. Edinb., M.R.C.P. Lond., Asst. Phy
the West London Hospital; Asst. Physician to the City of London Hospital, etc
Edition, Revised and Enlarged. In one very neat octavo volume of about seven hu

The call for a second edition of Dr. Fothergill's work has been met by the author with a re
formed in no perfunctory manner. The entire subject-matter has been submitted to a most ca
exhaustive scrutiny, and much new material been added, including articles on "The Functional
ances of the Liver," "The Means of Acting on the Respiratory Nerve Centres," "The Reflex Ca
of Ovarian Inoculation," "When Not to Give Iron," "Artificial Digestion," etc., thus present
plete reflex of the existing condition of therapeutical science.

CLINICS.

Clinical Lectures.

N A CASE OF ENLARGED SPLEEN, WITH REMARKS ON THE MALARIAL CACHEXIA.

A CLINICAL LECTURE DELIVERED AT THE PENNSYLVANIA HOSPITAL.

BY JAMES H. HUTCHINSON, M.D.,
ONE OF THE ATTENDING PHYSICIANS TO THE HOSPITAL.

GENTLEMEN: It could only be a rare accident which would give me the ortunity of showing you, at this season of the year, any of the severe or te forms of malarial disease. These are, it is true, occasionally met at er times than the latter part of the summer and the autumn, in sailors d others who, having been exposed to the causes of the disease in southern ntries, have sickened on the voyage home and been brought upon their ival at this port to our hospital for treatment. But such cases must be equent, since I have not had one under my care for several years. eed I am inclined to the opinion that, even in autumn, they are domer seen now than formerly, and that when they do occur they are milder type. May it not be that as our country is becoming more kly settled and consequently more thoroughly drained and cultivated t malaria, whatever may be its source, is growing less virulent and its cts less severe? In the time of Sydenham marsh fevers are known to e been very prevalent throughout England. Among its victims were es I. and Cromwell, who died of attacks of these diseases, contracted s said in London itself. At the present time, on the contrary, there e but few places in England where they occur in any but the mildest m. It does not seem, therefore, too much to hope that a similar change gradually taking place in our own land, and that these diseases will time disappear from at least the Middle and Eastern States.

At present, however, a large proportion of the sickness which is met h in this city and the surrounding country is directly or indirectly ibutable to malaria, and I have therefore determined to take as the ject of this morning's lecture, the results of chronic malarial poisoning, known under the name of "The Malarial Cachexia." The case I shal presently bring before you illustrates in a high degree a particular for of this cachexia, but I shall give my remarks a wider scope and sha refer as fully as time will permit to some of the other ways in which i may manifest itself.

In the first place then I never pass through my term of service witho having several cases of what are known as "vernal attacks of intermi tent fever" to treat. These almost invariably occur in persons who ha passed through an autumnal attack of greater or less severity, when owi to some exposure to cold, or to some other exciting cause which cann always be distinctly made out, they are unexpectedly seized during t latter part of winter or in the early part of spring with a recurrence of t disease. In a few cases, as in a case at present under treatment in t wards, the vernal attack would seem to be the original one. But in mo of these it is at least probable that the autumnal attack has been irregu or of such slight severity as not to have arrested attention. Occasionall however, in consequence of the patient's powers of resistance, the d ease does not show itself until long after exposure to its cause, and th only as a result of something having occurred to lessen this resisting pow Hence, attacks of intermittent fever are not uncommon in soldiers w have successfully withstood the causes of this disease until they have be wounded, when they have at once succumbed to them. As a gene rule the patient rapidly recovers under appropriate treatment. Still ca are occasionally encountered which show a high degree of obstinacy treatment. This tendency to relapse is an interesting feature of the d ease; it is, however, universally recognized, and it is not my intention t morning either to dwell upon it or to attempt to explain it.

My purpose is to speak more particularly of that form of malarial chexia which occurs in cases in which there have been at no time par ysmal attacks, or in which these, after continuing for some time, have length yielded to treatment. It is a matter frequently of the great importance to recognize this condition, as it demands a special treatme

I will now bring before you the patient to whom I have already referr The following history of his case has been drawn up from notes taken the bedside by my clinical clerk, Dr. Joseph M. Fox.

J. P., æt. 44; married; a native of Sicily; laborer; was admitt into the men's medical ward of the Pennsylvania Hospital February 1880. The patient states that his parents were healthy, that so far as knows he is not hereditarily predisposed to any disease; and that he h never had syphilis. He appears to have enjoyed uninterruptedly go health until sixteen years ago, when he contracted intermittent fever. H has since suffered from frequent recurrences of this disease, having had all as many as twenty-four attacks. The attack previous to the pres one occurred above nine months ago. He has been in this country o fifteen days. On the last three or four days of the voyage here, he say he felt poorly, but had no chill until ten days after landing, when one a companied by vomiting and a good deal of gastric distress occurred. H asserts positively that he did not notice that his abdomen was enlarg until three days before coming to the hospital, and that his attention w then called to it only by the presence of a good deal of pain. He say however, that it was enlarged, but not so much as it is now, about twel years ago, but that this enlargement subsequently disappeared.

Upon admission, the patient is pale and emaciated. His skin and conjunctiva are both yellowish. His tongue is pale and slightly coated, his appetite poor, and his bowels are inclined to constipation. At the angle of the jaw upon both sides there is a distinct swelling which apparently involves the parotid gland; the swelling is free from redness, and can be freely handled without giving him pain. Upon examining his chest a few sibilant râles and a well-marked hæmic murmur are heard.

The abdomen is very much enlarged, especially upon its left side, which is very prominent. It measures thirty-seven inches in circumference. Upon examination by percussion the liver dulness appears to be somewhat diminished in area. This is probably due to the tympanitic condition of the bowels, which renders the examination of the liver difficult. The spleen can be readily felt through the abdominal walls, and extends a little beyond the median line just above the umbilicus and down behind the crest of the ilium below. In the anterior axillary line of the left side, dulness begins at the fifth interspace; on the back it extends almost to the vertebral column.

The following are the results of an examination of the urine: Colour dark. Reaction, and specific gravity, 1016. Contains no albumen, and no sugar. No casts seen under the microscope.

The blood was examined by the pathologist of the hospital, Dr. Morris Longstreth, and this is his report: "A microscopic examination of the blood showed the following. The red corpuscles are irregular in shape and size, and form themselves poorly into rouleaux. Most of them show a tendency to alter in shape—to become double convex. The white corpuscles also vary in size and are slightly increased in number; a few more of them being seen in a field than in health, but the blood is not leucocythæmic. There is no evidence of pigmentation.

This case presents, as I have said, many of the most prominent characteristics of the malarial cachexia. In many cases, indeed in the majority, we do not have jaundice, but only a dirty-yellow or ashy-gray discoloration of the skin. The attack of intermittent fever from which the patient has recently suffered is probably the cause of this by giving rise to congestion of the liver. In many cases also in which the patients are not ill enough to take to their beds, depression of spirits and indisposition to exertion, whether mental or physical, are marked peculiarities. In cases of greater severity, œdema of the lower extremities, and even accumulation of liquid in the serous cavities, may be present. In others, dyspeptic symptoms may be the prominent ones, the patient complaining of furred tongue, disagreeable taste in the mouth, a sense of weight in the epigastrium, and of constipation or diarrhœa. Sometimes he suffers from epistaxis or other hemorrhages, which occur as the result of impaired nutrition of the walls of the bloodvessels.

The examination of the blood has failed to disclose in this case the existence of pigment granules and masses, upon which so much stress has been laid by recent writers, and, among others, by my colleague, Dr. J. Forsyth Meigs. These are found in most cases, in which the malarial cachexia is at all decided, in the blood, the spleen, the liver, the kidneys, the brain, the spinal cord, in fact, in almost every organ and tissue of the body. It is probably well known to most of you that Dr. Meigs connects with the presence of these granules in the blood, the tendency to the recurrence of attacks of intermittent fever which is so common a feature of the disease. He says, in his article on the subject in the first volume of the Pennsylvania Hospital Reports, "The masses might be supposed to retain in a dormant state the original poison, from the union of which with the blood corpuscles they had resulted. Then if the circumstances, such over-exertion or hot weather, which are prone to bring on a renewal the disorder, are those also which facilitate the resorption of the matt in the blood, the miasmatic influences would be again at liberty to act." This is, however, only an hypothesis which is far from proven, so that this tendency to relapse remains an enigma which no one has as yet bee able to solve. Still a great many of the symptoms of the malari cachexia are fairly attributable to the accumulation of pigment in th blood and tissues. It is sufficient for our present purpose to say that can thus explain the discoloration of the skin, the interference with th functions of the liver, and the occasional occurrence of brain sympto and of albuminuria.

In most of the cases in which the blood has been carefully examine there has been found, in addition to the changes noted by Dr. Longstret a decrease in the amount of albumen and fibrin. Hertz has been able demonstrate, in some cases a diminution in the size of the white corpuscl which were no larger than the red. Occasionally, also, the red corpuscl are nucleated.

It has been generally thought that the spleen is the principal seat the formation of this pigment matter, and that it is thence distribut throughout the body. It is not difficult to conceive that during paroxysms of intermittent fever, when the organ is enlarged and disten with blood, a destruction of the corpuscles, and a subsequent transfor tion of the hæmatine into pigment may readily take place, especi when a high temperature coexists. But there is also reason for believ that this change may take place in the liver, and even in the blood its as pigment masses of such a size as to preclude the possibility of th having passed through the capillaries of the liver and lungs are frequen found in the vessels of the brain. That the spleen also may be the s of extensive disease without causing pigmentation of the blood is sho by the case before us. There are, moreover, several diseases accompani by enlargement of the spleen and by a high temperature, in which pi ment granules are not formed in the blood.

The patient illustrates one of the most common results of chronic mal rial poisoning, although it is not often met with in as high a degree development. I allude, of course, to the enlargement of the sple This is so common a result of long-continued intermittent fever, that it popularly known under the name of ague-cake. This condition is gen rally attributed to the frequent congestions of the organ which occur du ing the paroxysms, and which at length bring about a change in its stru ture. In a certain number of cases this explanation fails, as ague-cak have been found in cases of chronic malarial poisoning in which no chi have occurred. Indeed, Piorry and Meckel look upon the spleen as th primary seat of the disease, and regard the paroxysm of intermittent fev as simply the consequence of the engorgement of the organ. We are here however, again met by the difficulty that intermittent fever has occurre without the slightest swelling of the spleen. Indeed, in a case reported in Canstatt's *Jahresbericht* for 1860, and referred to by Hertz in Ziemssen's

Cyclopædia, the spleen would seem to be unnecessary for the development of this disease.[1]

The spleen in the case before you is enormously increased in size. In some of the published cases, the organ is said to have been fifteen or sixteen times as large as in health, and to have weighed from 30 to 32 pounds, as in the cases reported respectively by Portal and Lieutaud. It is found after death to have become denser, tougher, and darker in colour, than in health, and to show upon section in old cases a great increase of the trabecular tissue at the expense of the pulp, which in some cases has almost ntirely disappeared. Occasionally there are evidences of amyloid degeneration, and this change many coexist with a similar one in the liver and spleen. Not infrequently it is found connected to adjacent parts or rgans by adhesions, the consequence of previous attacks of peritonitis. Greater proportionate enlargement is said to occur in children than in dults, because the fibrous capsules of the organ in the former is more stic, and hence permits of a greater distension. No age is exempt om the liability to ague-cake. Cases are on record in which it has been und in children at birth in malarious regions.

The ague-cake is hardly likely to be mistaken for any other tumour, pecially in a case in which we have such an unmistakable history of ronic malarial poisoning as in the one before us. An enlarged left kidney said to have been taken for it, but we have in this case nothing in the story or symptoms to justify a suspicion that the kidney is the seat of the sease. I remember in the earlier part of my professional life having garded an ague-cake as a solid ovarian tumour, until I had thoroughly amined the case, when its nature became clear enough. Besides the ysical characters of an enlarged spleen, which are sufficiently distinct in s case, the examination of the blood points towards the spleen as the gan affected, as it is not usual to find the changes in the blood which I ve described, present in other forms of disease.

The patient tells us that he noticed that his abdomen was swollen only few days before coming here. Are we then to conclude that the enlargement of the spleen has existed for only a few days? I unhesitatingly swer, decidedly not. The very size and apparent density of the organ nder this unlikely. It is not uncommon for persons in his class of life overlook conditions which do not give them pain or make the earning their daily bread impossible. It is more probable, I think, that the 'swelling" which, he says, he noticed twelve years ago, has existed in a reater or less degree ever since.

The prognosis in the case, marked as it is, is not hopeless. Already nder the treatment I have instituted, some improvement has taken place, d I confidently look forward to more before discharging the patient. saying this I do not mean to intimate that it is possible to restore the pleen entirely to its former healthy condition. A certain amount of amage has been inflicted upon it, which is, of course, irreparable.

The examination of the liver has given in this case only negative results. till it is very unlikely that this organ is in a perfectly normal state. ndeed, the jaundice, under which the patient is now suffering, would eem to indicate the existence of some chronic changes in it. In a report of several cases of remittent fever, observed in this hospital by Dr. Thomas Stewardson about the year 1838, certain marked alterations in the colour and consistence of the liver were for the first time described. Great importance was attached to these changes by Dr. Stewardson, inasmuch as he believed that their natural tendency, when long continued, is to pas into cirrhosis, and thus lay the foundation of some of those chronic disorders to which the disease frequently gives rise. Other authors have also called attention to the occurrence of cirrhosis and amyloid degeneratio of the liver as results of remittent fever. Cirrhosis may be rare as a consequence of chronic malarial poison, but there can be no doubt o the prevalence of diseases of the liver in the unhealthy portions of ou country. .

---

[1] A man received an extensive wound of the abdomen in the left side through which e spleen escaped, and, as it could not be returned, it was removed. The patient recovered from the operation and subsequently had malarial fever. Eventually a post-mortem examination showed nothing but the shrivelled rudiments of the spleen left.

The kidneys are frequently implicated in the graver forms of malari disease, and there is good reason to believe that the changes which occu during acute attacks are sometimes permanent. In other words, Bright' disease may, in some cases, at least, be the result of remittent fever. Ou of fifty grave cases of this disease which Frerichs had the opportunity observing at Breslau, albuminuria was present in twenty-one; and i some of the fatal cases the kidneys are said to have been extensively di organized. Similar changes are described by Key. In looking over m notes of cases of Bright's disease I have been struck with the frequency the occurrence of intermittent fever as an antecedent disease to that of t kidneys. In one case this connection was so remarkable that I shall gi you a brief abstract of its history.

E. J., æt. 21, unmarried, American, was admitted into the medic ward of the Pennsylvania Hospital, Feb. 5, 1872. The patient's fami history was good. He stated that his health was good until the autu of 1872, when he had a severe attack of what he calls "swamp feve which he contracted while working in the low lands near the Mississi River. The attack lasted for six weeks, and was accompanied by serio diarrhœa. Since then, attacks of ague have repeatedly occurred. January, 1871, or about two months after apparently convalescing fro his remittent fever, his legs became dropsical. With the exception diminished quantity, he noticed nothing abnormal in connection with t renal secretion, and this he ascribed to the loss of a large quantity of wat by the bowels. In the following March, the dropsy disappeared, but r appeared at about the end of September, when he was admitted in the hospital, but was allowed by his friends to remain at this time for few days only. During his stay in the hospital his urine was, howeve examined and found to be highly albuminous. After his second admissio his urine was again examined with the following results: Quantity pass in twenty-fours, f℥xxxij; colour, pale yellow; specific gravity, 1016. contained albumen one-half by bulk. Upon standing it lets fall a whiti deposit, which, under the microscope, was found to contain numerous pal granular, and fatty casts with a few that were hyaline. The patient eve tually died of peritonitis. At the autopsy, the kidneys were found to b examples of the condition known as the "large white kidney."

May not then malarial fever be occasionally the cause of Bright's di ease, just as various other acute febrile diseases are now known to be There are certainly some cases which it is difficult to explain in any othe way.

Sometimes the effects of chronic malarial poisoning are shown in som derangement of the nervous system. All of you are probably aware ho frequent, especially in women, are attacks of supra-orbital neuralgia in those who have been exposed to malarial emanations. They are usually known as "brow agues," and often occur in persons who have never had a regular attack of intermittent fever, and hence their nature is not rarely unrecognized. They may, however, be readily distinguished from other forms of neuralgia by their paroxysmal character, and by their generally yielding to antiperiodic doses of quinia. Occasionally more threatening nervous symptoms occur in the subjects of the malarial cachexia. I have a patient now under treatment in private practice, who has an epileptiform convulsion regularly with every paroxysm of intermittent fever, although he was not previously to contracting the latter disease the subject of epilepsy. An attack of intermittent fever has, in some cases, appeared to exercise a curative influence upon epilepsy; but in the case just referred to I fear it may induce such changes in the brain that my patient may ecome a confirmed epileptic, especially as I find it difficult to induce him take sufficiently large doses of quinia to exercise a controlling influence er his disease. In other cases delirium or coma suddenly supervenes in e course of the malarial cachexia. These various symptoms are ascribed y many writers to the presence in the brain of the pigment masses and anules which I have fully described in the earlier part of my lecture. ese have been discovered in the brain long after recovery from the ute disease to which they owe their origin, as in a case in which Dr. eigs found the brain discoloured by them eighteen months after an attack remittent fever. It does not seem unreasonable to suppose that they capable, under certain circumstances, of acting as irritants to the in. Still it is only right to add that coma, delirium, and convulsions, ve all occurred in cases in which the brain has appeared at the autopsy be healthy, and have been absent in others, in which it has been found ded with pigment.

The heart usually shares in the general impairment of nutrition present the malarial cachexia; its muscular tissues being found in those cases ich terminate fatally, pale and soft. The murmur, which is heard in s case is, however, of hæmic origin, and is not due, I feel sure, to or- nic disease.

I have left myself but little time to speak of the treatment of the mala- l cachexia. No matter what form it may assume it demands the same neral treatment, and this consists in the administration of full doses of inia, generally given in combination with iron. In this case it is proper course, in addition to giving these remedies to attempt, if possible, to duce the volume of the spleen. Up to the present time I have contented yself with painting the tincture of iodine over the tumour. Electricity s been recommended for the reduction of these tumours, but thus far all e trials which have been made with it have resulted in failure. Oint- ents made up with various preparations of mercury have been used, d it is asserted, with success. If the patient were less broken down, s cachectic in appearance, I should be disposed to inject subcutaneously solution of extract of ergot in glycerine, as has been done successfully, similar cases, by my colleague, Dr. Da Costa, but I fear the produc- on of abscesses. Mosler has recently recommended the injection of tinc- re of iodine into the substance of the organ itself. But I hesitate to ve recourse to a procedure not without danger to the patient, until mpler means of treatment have been tried and failed. In obstinate cases n which little or no improvement has taken place after quinia has been given a fair trial, good results will often be obtained with arsenic, whi may be administered alone, or in combination with the bitter wine of iro The derangements of the stomach and bowels, when present, must be m by the appropriate remedies. I have seen good results follow the occasio use of mercurials.

NOTE.—At a subsequent lecture the patient was again exhibited to th class, for the purpose of showing the improvement that had taken place i his condition. The spleen was apparently reduced to about one-half of i previous size. The treatment I directed in the lecture has been carri out, and when he seemed in a sufficiently robust condition to bear the the subcutaneous injections of ergot were administered to him, but h to be almost immediately abandoned on account of the production abscesses. Ergot was subsequently given to him by the mouth, and it w thought with advantage.

A short time afterwards, although the spleen continued enlarged, t patient, feeling perfectly well, demanded his discharge.

ON VAGINITIS.

By J. MATTHEWS DUNCAN, M.D., LL.D.,

Physician-Accoucheur and Lecturer on Midwifery at St. Bartholomew's Hospital.

GENTLEMEN: My lecture to-day is upon Vaginitis, a disease which is so c ously illustrated by cases in "Martha" that, although it cannot be expecte strike you, it strikes me very forcibly that it is greatly neglected in medical prac and in medical literature. This arises from two circumstances: it is often chr and slight and it often forms a part of a more extensive disease, of which o parts are much more urgent and attract the whole attention of the observer themselves. If a woman, for instance, has chronic vaginitis and ovaritis, case will probably be called ovaritis, and there will be a risk of the vaginitis ing neglected. If a woman has acute vaginitis and cystitis—which latter is of the most painful and urgent of diseases,—it is likely that the vaginitis will neglected. The frequency of this disease gives it great importance.

Before I consider the parts of the subject which are to form the chief topic my lecture to-day, I must get a few statements out of the way. Diphther vaginitis is a rare disease: I have seen it. Erysipelatous vaginitis is a rare ease; and there is a peculiar form of it which is rarer—a diffuse inflammatio the external cellular coat, causing swelling which almost occludes the whole len of the passage; and when this ends in suppuration, it sometimes so dissects the tube of the vagina as to deserve the name of para-vaginitis dissecans. Lat I have seen a case of vaginitis with similar inflammation of the cervix ut where the disease consists of rounded sloughing phagedænic ulcerations, of or two lines broad, for whose origin no satisfactory syphilitic account could given; the ulcers were on the lacquear vaginæ and on the cervix. Then ulcerous vaginitis ending in adhesions is described; and I have seen a pustu vaginitis.

Besides these different kinds there are varieties of vaginitis as where the di ease attacks only parts of the passage, as the lacquear, in which case it is ve frequently associated with inflammation of the cervix uteri. It also frequen attacks the lower part alone of the vagina, and in that case it is often associated with inflammation of the pudendum. Besides, the inflammation may be of small parts, so that, when the vagina is looked at, it has a mapped, or a marbled, or a ottled appearance. I have seen also a vagina spotted like a Dalmatian dog, as f the chronic inflammation were only around the openings of numerous little ucous follicles, regularly arranged. Again, as in a case which I showed you in "Martha" last Tuesday, the inflammation may so affect the ridges of the rugæ f the vagina that they alone appear red, the sulci being pale.

Now for a great matter. Vaginitis may be a local or a constitutional disease. he characteristic acute vaginitis, gonorrhœa venerealis, or the same disease ocrring after marriage, or the same disease occurring after the introduction or ring the wearing of a pessary, are examples of local—purely local—disease. the disease is severe it draws the constitution into sympathy with it, and you e a constitutional affection secondary to the local.

But a large number—indeed, I think the majority of cases—are constitutional their origin: they exhibit an order the reverse of that which I have mentioned characteristic of local diseases; it is the constitutional that brings on the local ction secondary to the constitutional.

In this hospital it seems natural to speak at length on the constitutional origin d treatment of local disease, of which Abernethy made so much. The ject, as he discussed it, was very imperfectly known; and indeed now our owledge is very deficient. A great deal of the details of what has been said, d some of what I have to say, is mere arbitrary statement; but the great princles are so important that I must enter upon them at some length.

There is an inflammatory diathesis which accounts for the occurrence of local ases, and this is occasionally well exemplified in lying-in women. Such, while and tenderly cared for and scrupulously nursed, and after the time of septiia and pyæmia are far past, may have a violent attack of pleuritis or pleuroumonia, for which no explanation can be discovered, and which begins and s as a simple inflammatory disease, but not a mere local disease: it springs a constitutional origin, and this origin we call the inflammatory diathesis for t of a more definitely intelligent name. Extraordinary examples of this I e seen; several cases, indeed, such as this: After a week of health recovery, come puerperal insanity, double pleuro-pneumonia, double nephritis with uminous urine, and double or right and left parametritis; all beginning and ding as purely inflammatory affections, without any discoverable reference to d or septicæmia. In the case of simple local vaginitis, as in the analogous orrhœa in the male, the occasional occurrence of arthritis is alleged as evidence a constitutional affection. This arthritis I feel bound to believe in, but I have er seen it; and for that reason I shall say nothing about it.

When vaginitis occurs as the result of constitutional disease it seldom occurs alone, ough it may do so. It is generally accompanied by cystitis, and sometimes still more extensive disease. It is generally subacute, as is the cystitis which en accompanies it. Vaginitis and cystitis, each alone, or the two combined, are rare in old women as constitutional diseases. If they occur in conjunction, the titis being much more painful than the allied vaginitis may alone attract the erver's attention. Besides being subacute a constitutional vaginitis is likely be chronic: it will probably continue so long as the constitutional condition ich gives rise to it persists.

What are the constitutional conditions which give rise to vaginitis? Alcoholism the most important; the next is old age; the next is lupus, or rather the contution accompanying lupus; and the next is diabetes, and in this case the vagitis is generally accompanied by vulvitis.

The importance of this distinction of vaginitis into local and constitutional i seen in treatment. A local vaginitis is to be managed almost entirely by loc treatment. A constitutional vaginitis will be very imperfectly and unsuccessfu treated if you pay attention only to the local treatment; whereas if you p attention to constitutional treatment, and even omit local treatment, you w succeed. In cases of this kind striking successes in practice are often seen. Y are called to a case of a drunken woman who has, as is not very rare, inflamm tion of the kidney, bladder, urethra, and vagina of a subacute kind, and are to by the practitioner that he has tried every medicine he can think of. His ther peutical method, in its highly diluted copiousness, reminds one of the garrul of little knowledge. In such a case, I say, if you recognize the constitutio origin of the disease, then the line of treatment is at once indicated, and y achieve brilliant success. You make the drunkard a teetotaler, and the vagini disappears. An illustration, foreign to the genital organs, may be of use: The is a form of conjunctivitis which is produced by chloralism. Now, if an ocul were treating this in ignorance of its cause, what a failure he would make! would feel that a disease usually easily cured was beating him, and he might tempted to try something else, and again something else; whereas, if he kne the cause, he could cure it at once. *Sublata causa tollitur effectus.*

Besides that this disease may be local or constitutional, there is another ve important thing to remember about it—namely, that it is frequently part o more extensive malady.

This is true of local vaginitis, and the more extensive malady is the affecti of neighbouring organs. In cases of acute vaginitis the spreading is by continu A woman has venereal gonorrhœa. It is not improbable that she will have e metritis, ovaritis, perimetritis, urethritis, cystitis, and ureteritis, and per nephritis. The whole disease here is local; it was begun by the poisoning of vaginal mucous membrane. The treatment of the local disease is essential in case, but the other diseases must be attended to, and they may persist after cure of the original local affection.

When the disease is constitutional, the vaginitis is, as I have already sa generally only a part of a more extensive malady. I saw a case, for insta not very long ago, during pregnancy, and another case in an old woman ab sixty, where the constitutional disease was alcoholism. Both had purulent l corrhœa; both had urethritis, which in the old woman was so severe that y could bring out pus from the orifice of the urethra. Both had irritable blad and albuminous urine, this secretion being in the old woman sometimes tinged blood. In both the vaginitis was an important part of the disease compared w the affection of the urinary organs; and this latter justly attracts almost whole attention of the practitioner. In such cases the urine is of low spec gravity; opalescent, and remaining opalescent after standing; it deposits mu with phosphates and lithates. The microscope detects pus, bladder epitheli and epithelium of the ureters. Albumen is thrown down after boiling.

This inflammatory affection of the whole genito-urinary organs by alcoholi and of which vaginitis is a part, is not a disease which stands alone. There i well-described disease, for instance, which affects the same systems of orga and them alone, in women, called genito-urinary tuberculosis, a good example which in the post-mortem room is one of the most interesting sights I know.

You are not to suppose that vaginitis is a usual result of alcoholism. In th not pregnant and not old a more common result is ovaritis and endometritis, l those produced by fevers. But whereas the ovaritis and endometritis of fe are temporary, the same diseases of alcoholism are only temporary if the al holism is also temporary.

example of another form of constitutional disease producing vaginitis I
ead to you. Here the vaginitis is connected with lupus. I shall not now
ou the characteristics of the recurring vaginitis of lupus, because you will
ne read them in this report; and I ask your attention to the fact that the
tis was rapidly improved while the patient was under our care.

s form of vaginitis is often easily cured, but it is very liable to relapse: for
classed it as of constitutional origin; and who will remove lupus from the
ution? The woman has myxœdema or cretinoid disease; she has lupus
us of the orifice of the urethra and around the vaginal orifice; and she has
es. She came to us to be treated for vaginal discharge.

K., aged forty-one, married twelve years; has had two children, no mis-
e; last child born ten years ago, husband having been absent since then.
he measured eighteen inches in girth at the waist before her last pregnancy;
w measures thirty-eight inches. Hands and feet were then small and fine.
lly, during the last ten years, she has grown weaker and bigger. Hands,
ce (especially lips and nose), and neighbourhood of umbilicus, have be-
hickened and coarse. Hands most affected, being thick, corrugated,
, like those of a labourer, with the nails coarse, dirty-looking, and flat-
She has lost power to a great extent in arms and legs, being unable to
nything firmly, and finding it tedious and difficult to thread a needle. She
see, hear, smell, or taste as formerly. Ophthalmoscopic examination re-
othing abnormal in the eyes. For the last three months she has been
large quantities of water, and has not been able to retain it above a minute
e desire to urinate was felt. The quantity now passed is about a pint at
; it has a specific gravity of 1042, and contains much sugar. On succes-
ys she has passed 5½, 6½, 8, 6, 4, 7¾ pints. The fourchette is entire; at
de, and arranged around, and external to the proper vaginal orifice, are
d and tender patches. The vestibule between the clitoris and urethral
is red and pitted. The posterior half of margin of urethral orifice pre-
prominent, caruncle-like ulcer with everted edges, not extremely sensi-
The cervix uteri contains an opaque (not yellow) mucus. The vagina has
ly-looking, mottled red surface, painted over with copious thin green pus;
ace is smooth, and no rugæ are seen. She has been treated for a few days
vaginal injection of black-wash, and already the vaginitis has nearly gone,
face looking scarcely redder than natural—not smooth and glazed as be-
ut presenting rugæ, and the pus being laudable.

ch, or age, here produces, not different diseases of the vagina (such differ-
as I illustrated in my last lecture), but it produces vaginitis of different
You have no vaginitis in childhood. I, at least, have never seen any
of the lower part adjoining the hymen. Then, during mature life, you
he characteristic acute vaginitis, the venereal gonorrhœa, or a like disease,
may owe its origin to perfectly pure sexual intercourse. An acute vaginitis
to be so designated, unless it has the combination of characters necessary
tle it to that name. You must have intense inflammation rapidly coming
er the cause has acted, coming to a climax in eight or nine days, and then
y fading and going away altogether, or becoming chronic; and you must
during the height of the disease, a copious flow of laudable pus.

e vagina in this disease generally presents a red, raw-like surface, beneath
there is little œdema, the rugæ not being obliterated. It is sometimes
ated, which probably arises from the injection of papillæ, and it is often
lated from the same cause.

e vaginitis of old age is generally subacute, and a similar disease is not rare
g pregnancy and in the puerperal state. Rarely does the vagina, when in-

spected, present the same appearance as in the acute vaginitis of youth. It i more frequently smooth, having a glazed appearance and feeling, the rugæ bei obliterated and reappearing as the disease is cured; and sometimes you see ar over which the mucous surface seems to be destroyed, and these bleed readi especially when touched. In many of these cases you are consulted not for va nitis, but for so-called menorrhagia, which the woman supposes she is sufferi from; and, as you know, this is an alarming symptom in old women.

This disease, especially in old women, leads to garrulitas vulvæ, not the g rulity of feeble-mindedness to which I have before referred. The vagina secret air, and the woman may be extremely annoyed by passing it from the bod This is not the only explanation of passing air from the vagina, but it is the o one I at present mention; and I may remind you of the disease called vagi emphysematosa. In the subacute vaginitis of old women the bladder is v often simultaneously affected. The pus is generally thin and green. It is so times extremely copious. Although the disease may depend greatly upon permanent constitutional influence of senescence, it is upon the whole amen to simple treatment. The vaginitis of the old is probably the cause of those c mon, partial, thin-edged vaginal strictures which are so frequently found high the passage.

Now, besides these two forms of acute vaginitis, the vaginitis of mature and of old age, you have chronic vaginitis.

Chronic vaginitis of youth occurs in various forms. There is a chronic va nitis in which the vagina is hard and small, its rugæ well seen, but yet evide swollen, œdematous, and with either no secretion or with the rugæ painted o by an old gray-white accumulation of sordid epithelial detritus. This kin vaginitis is not rare, and it sometimes escapes notice, because, although it ma connected with vaginismus, it often produces no symptoms. Of this form we a case in "Martha" a few days ago.

This, which may be called dry vaginitis, has its analogue in a disease of deep cavities of the nose, which I have suspected as producing peculiar head and giddiness, and which is assuaged or cured by the same soothing remedie act on the disease in the vagina. Another disease I may mention, remo analogous to this. Many of you remember the last ovariotomy performe "Martha," and you must have seen that woman's uterus pulled out of the pel red and having the appearance of a fresh section of raw beef. That was a c of dry chronic peritonitis without any secretion or symptoms. It did not in fere with her good recovery.

In some cases the cervix uteri is diseased as well as the vagina, and I shall n an example which occurred in "Martha" lately. In this we had, probably result of an acute vaginitis, a chronic vaginitis accompanied by cystitis, urethri and only imperfectly cured after long perseverance.

S. H., aged twenty-seven; general health good; has been married more th a year, but has not been pregnant. Has been under treatment, in another wa for some months, for chronic catarrh of the bladder. Had an abscess in a labi majus, and yellow vaginal discharge, before admission to the hospital. Her urg symptoms depend on frequent calls to painful urination. Private parts so ten as to necessitate the use of chloroform in most of the examinations. Vulva, v tibule, hymen, intensely red. Bladder hard, exquisitely tender, contracted so to have only two inches from orifice of urethra to fundus. Laudable pus flo from vagina, and can be expressed from urethra. Speculum shows vagina to red; rugæ not seen; surface not granulated, but has an œdematous appearan Uterus healthy. To have hot hip-bath and morphia suppository at bedtime, paiba mixture several times daily. Bismuth powder lotion twice daily per nam. Milk diet. Saline laxatives when required. Not to get out of bed. r this treatment she gradually improved. Subsequently the bladder was washed with an acidulated solution of sulphate of quinine, two grains to an ; and still later with subnitrate of bismuth suspended in water. After months of diligent treatment, the vaginitis and urethritis were cured, the er had greatly increased in capacity and was less irritable, but the urination till unnaturally and distressingly frequent.

e chronic vaginitis of old age, as I have already said, is generally accompa- by pruritus, and frequently causes alarm by bleeding. Here is an example in which we have, besides the vaginitis, incurable hypertrophy of the a.

S., aged forty-seven, has been married for twenty years, and has had three en, no miscarriage; the last child born twelve years ago. Catamenia began teen years of age, and continued (with some irregularity the last twelve till a year ago, when they ceased. For nine years has had a green discharge from the vagina, which is, at least sometimes, fetid. Coitus ainful for the last two years. Her appearance is unhealthy, and her urine led with lithates. The urethra is hypertrophied, hardened, and feeling small finger. Except slight redness, it presents no unnatural appearance eye. It is tender to touch per vaginam and on using the sound. The r and womb are natural. The vagina has a polished, slightly reddened, surface, which readily bleeds at various points when touched. Glycerine plugs were used for three weeks, and for a month she had twice daily an gent lotion of ten ounces of tepid water with thirty grains of alum, and as of sulphate of zinc in solution. She was discharged greatly relieved, yet ease was not quite cured.

ve mentioned many forms of vaginitis, and one important practical subject discuss briefly in connection with the forms of this disease. Is it, in any l case, venereal or not venereal? You will, in practice, often be asked estion, and I advise you never to answer it explicitly. You cannot decide tely whether a case is venereal or not. At one time it was supposed that scovery of trichomonads, or a leptothrix, or a vibrio, would decide whether venereal or not. But this is now given up. I have seen gonorrhœa which rtainly not venereal bear every character of the ordinary venereal disease. ot say that there is no distinction, but only that the distinction cannot be out by the practitioner so as to justify him, from his own inquiries into a n giving a decided opinion on the subject. Meantime, the distinctions of al gonorrhœa are simply marks of severity. It has been said that venereal hœa is infectious, while simple gonorrhœa is not; but I have seen every ter that can be predicated of the one occur in the other, as I said before, ing infection.

at are the characters that make you suspect that a vaginitis is of venereal ? It begins within a few days—generally two or three—of the infection; ery severe, and runs an acute course; the secretion of pus is copious, begin- bout the third day of the inflammation, and remaining copious for about a or nine days. The vulva is generally affected, so that the woman has more s difficulty in walking; and the vulva being affected, the inguinal glands able to be affected, and you may even have bubo. The urethra is affected, lso the bladder; there is liability to ovaritis and to perioophoritis; and there almost certain infection, not only by sexual intercourse, but by the matter ing any mucous surface, such as that of the eye.

ave little time to make remarks upon treatment, and indeed the treatment of this disease is illustrated by the cases I have read, and it is so well describ in every text-book that it would be only waste of this day's time to enter up it. It must be based upon a careful diagnosis, including the diagnosis of local or constitutional origin of the disease, the diagnosis of the simplicity of affection, or of its complication or extension to other parts.

The acute disease is treated by diet, and purgatives, and baths, and re Locally it is treated at first by emollient injection, such as that of decoction poppy-heads; and afterwards by other injections, such as that of dilute plumbi diacetatis; and at the end by injection of very dilute astringents, as of sulpho-carbolate of zinc. All these injections are made with such an instrum as I here show you. The injection is of about ten ounces, and it is passed slo through the vagina. It is good treatment, in a tiresome case, to apply weak, sometimes strongish, solution of silver nitrate to the vagina, and that is done a blunt-pointed glass syringe. You pass something like an ounce into the vag through it.

The chronic disease is treated in many respects as the acute or subacute, you place more reliance upon the use of powders suspended in water—such as white bismuth. An excellent remedy is a weak solution (five or six grain the ounce) of sulpho-carbolate of zinc; and I shall conclude the lecture by re ing to you a case of simple chronic vaginitis with smooth glazed surface, wh after we were afraid it would prove rebellious to treatment, was quickly cured the use of the hot douche. This is the injection into the vagina of a large q tity of water at a blood heat; and the water is injected, for several minutes, considerable force, which may be estimated by my telling you that it will th it four and a half feet high. This powerful remedy proved of curative val the case I am to read to you.

M. F., aged thirty-seven, has been married eight years, and has had no dren. The catamenia began at thirteen years, and were regular and some painful till recently, when they have been delayed sometimes to the exte two weeks. For about nineteen months she has suffered from pain in the tion of the vagina, yellow discharge, painful coitus; and in the earlier perio her illness she had painful micturition. She has slight pain on pressure over right kidney. No pain on defecation. The pain in the vagina comes in pa ysms several times a day. She says that the yellow discharge has latterly dim ished considerably. The finger finds an unnatural smoothness of the vag The speculum reveals no disease of the cervix, but the vagina is smooth, slig redder than natural, and painted over with yellowish muco-pus. After failure of long-continued ordinary treatment as an out-patient, and for a s time in "Martha," she was ordered to have twice daily the vaginal douche hot water at about blood-heat for some fifteen minutes each time. Of this tr ment she quickly felt advantage, and after five days of it she left the hosp quite well. The vagina had lost its œdematous smoothness, and was pale rugous in a natural manner.—*Med. Times and Gazette*, June 26, 1880.

MONTHLY ABSTRACT.

Anatomy and Physiology.

The Effects of Cerebral Stimulation.

movements which result when the cerebral motor zone of an animal is ted by electricity have been studied by means of the graphic method by 'RANÇOIS FRANCK and PITRES, and the results which they have obtained considerable interest. The method adopted was to connect a myograph e tendon of a muscle of the anterior or posterior limb of the animal exnted upon (dog, cat, or rabbit). The time elapsing before the movement istered by electro-magnetic apparatus. The first point examined was the er of the movements. When the cortical excitation is a single stimulus, traction on the opposite side of the body is a simple muscular jerk. A of stimulations not exceeding forty per second produce dissociated jerks. requency of the stimuli attains forty-five per second, in the dog, the musntractions are fused together in a continuous contraction. A similar freof stimulation is necessary to cause tetanus in any animal, whether the tion is applied to the surface of the brain, to a motor nerve, or to a mus-/hen, instead of employing stimulation sufficiently strong to cause isolated tions, stimuli a little less strong are employed, the phenomena of summaay be observed. The first stimulation gives rise to no muscular contracd the jerks only appear after several stimulations. If the excitation is or prolonged, after a simple movement, directly provoked, an epileptiform occurs confined to the group of muscles corresponding to the centre stimu-The attack may remain limited to this group, or extend to both limbs on le, or to the whole body. It is usually constituted by two successive the one of tonic contraction, the other of clonic spasm, in which the jerks ociated. Sometimes the initial tonic stage is absent. When one convulack has occurred, the least excitation suffices to produce another. The ions, local or general, are not produced if, instead of stimulating the cors is removed and the electrodes are applied to the subjacent white layer. even with the strongest stimulation, no convulsions occur, only simple ents result. The excitability of the white fibres increases as the internal is approached, so that, at this level, even weak stimulation suffices to e a violent tetanus, with periodical, often rhythmical, exacerbations; this s, on account of its special characters, the term "capsular tetanus."

lay occurs between the stimulation and the resulting movement, which is t for each group of muscles in the same animal, whatever is the form or ty of the electrical stimulus employed. A considerable part of this delay o the physiological resistance of the cortical gray layer. If the thin gray ce which covers the centrum ovale is removed at the point stimulated, e white substance is then excited, the total delay lessens by a fourth or y a third.

movements produced by irritation of one side of the brain are not always l to the muscles situated on the opposite side of the body; symmetrical tions occur on the same side if the stimulation exceeds a certain degree of ty. In this case the delay is greater for the associated movements on the same side than for the movements which occur on the side opposite to the hemisphere stimulated. When two points on the same side of the brain are simultaneously excited, the one corresponding to the upper limb, the other to the lower limb, the movement in the latter occurs at a later period than that in the former. This greater delay is probably due to the conduction in the spinal cord, the period of which, in the case of impulses proceeding from the brain, may thus be estimated.

A singular method has been applied by Dr. Amidon, of New York, to the study of cerebral localization. Instead of observing the peripheral effect of central stimulation, he has endeavoured to determine the effect on the brain of voluntary movements, estimating it by the change to be ascertained in the local temperature. Finding that the temperature on the surface of the skull varies at different points when certain movements are executed for a time, he infers that the point at which the temperature is thus raised corresponds to the centre for that movement. Ten of Seguin's surface-thermometers were applied to different parts of the skull, and maintained in position by India-rubber bands; and the temperature of the several thermometers observed after a muscular effort maintained during several minutes. Proceeding thus, Dr. Amidon believes he has established the position of a series of centres which do not altogether correspond with those ascertained by Ferrier. The results have been communicated to the Société de Biologie of Paris, and in the discussion upon them M. Paul Bert mentioned his own researches on the same subject. Employing a thermo-electric pile, with all necessary precautions, he found that talking in a loud voice caused an elevation of the temperature in the left anterior frontal region. He has also found a rise in the temperature of the head (ascertained in the frontal region) in children at the moment of waking. Examining the lateral regions of the skull, over the motor convolutions, he was never able to observe any change in the temperature on muscular exertion. This shows that the results of Dr. Amidon must be accepted with great caution, and it was suggested that the muscular exertion in the limbs may have been accompanied by contractions in the muscles of the head sufficient to cause the local rise in temperature. The negative results obtained by M. Bert in the motor region of the hemisphere render, for the same reason, the significance of the rise in temperature he has found in the frontal region during speaking very doubtful. One fact affording some corroboration to Dr. Amidon's conclusions was mentioned. One of the centres he describes is for the movement of the trapezius, and it corresponds to the part damaged in a patient of M. Poncet, in whom this muscle was paralyzed.—*Lancet*, June 12, 1880.

The Formation of Callus.

MM. Rigal and Vignal presented a note on this subject before the Paris Académie des Sciences, which is reported in the *Gazette Hebdomadaire* of June 4th. In 1865, M. Ranvier, in his *Thèse de Doctorat*, and in 1869, MM. Cornil and Ranvier, in their *Manuel d'Anatomie Pathologique*, taking experiments as their basis, showed that the callus in simple fracture, in the human subject as well as in animals, in the first instance went through a cartilaginous stage; whilst in compound fractures it became directly bony in the midst of fleshy granulations proceeding from the medullary substance of the fractured bone. M. Ranvier further demonstrated that the suppurative inflammation had no influence on the progress of ossification in the cartilaginous callus when this was already formed. The writers made the following experiment. From the middle third of the tibia of a full-grown rabbit, they removed the periosteum three or four times in succession, so as to thoroughly destroy all its osteogenic properties;

a fortnight after the last removal, they fractured the bone in the centre. re days after the fracture (at that stage there is always a cartilaginous callus rabbit), the animal was killed, and the examination of the fracture showed n the midst of the fleshy granulations, proceeding from the enlarged canals vers, a distinctly bony peripheric callus had formed. This experiment, l times repeated, always yielded the same results. The following experiis still more conclusive. The periosteum was removed on two occasions at night's interval. The wound being cicatrized, the bone was broken in the e, as in the first experiment, and the animal was killed twelve days subsey. At the posterior part, where the periosteum had been preserved, the had formed, as in simple fractures, by the aid of cartilage; whilst at the or part it was formed in the midst of fleshy granulations, as in suppurating mpound fractures. These experiments seem, then, to prove that the subteal layer, when the irritation is active, as in fractures, contributes to the of the bone by becoming transformed into cartilaginous tissue. In another ment, made on the same animal, the other conditions besides those to be d being exactly the same, after having divided the skin of one of the legs refully put aside the muscles until the periosteum was reached, the latter mewhat strongly irritated by rubbing it with a highly polished surface—an burnisher, for instance—taking care not to touch the adjacent parts. On pposite leg, the periosteum was irritated by thoroughly breaking up the nt soft parts, so as to bring on a sanguineous effusion. Then both wounds closed by points of suture, and the animal was killed between the tenth welfth days. If union by first intention of the wounds in both legs had obtained, some osteophytes would have been found under the periosteum first, whilst under that of the second larger or smaller cartilaginous masses have been found. The last experiment explains the direct bony formaf the points of subperiosteal callus the furthest from the seat of the fracture. *tish Med. Journal*, June 19, 1880.

The Blood in Febrile States.

Hayem, who has added so much to our knowledge of various morbid states blood, has lately published some observations on the minute alterations in ode of formation of the coagulum in various febrile states. When the blood ead out in a thin layer under the microscope, the corpuscles are seen to assume ial arrangement. The irregular spaces which the rouleaux leave are larger ess numerous than under normal conditions. If, after coagulation, an pt is made to separate the elements, it is found that the corpuscles are l by extremely fine filaments of fibrine, which cause them to assume very lar shapes; they present also an abnormal viscosity when compressed by the nding fibrine. Other changes which the blood presents cannot be, with nty, ascribed to the inflammatory processes. Even when the pyrexia is there is no alteration in the dimensions of the red corpuscles. The increase e number of leucocytes affects equally all forms of palę corpuscles, their al proportion being about the same as in normal blood. Nor do these preany structural alterations; their amœboid movements are the same as in h, except that they are somewhat interfered with by the filaments of fibrine h adhere to them. Many "hæmatoblasts" occupy the empty spaces, and like red corpuscles, they become more viscous and adherent one to another, and e quickly form masses, notably larger than those seem in normal blood. y soon a reticulum appears, considerably denser than in other circumstances, constituent filaments being thicker and closer than those of normal blood.

During this formation, the hæmatoblasts have fused together into little blocks waxy aspect, to which large numbers of fibrils are attached, giving them a ch acteristic appearance of balls of spines. The excess of fibrine in the blood giv rise to another appearance if the blood is diluted with the liquid used in the or nary numeration of the corpuscles; minute solid particles become visible to th naked eye in the mixture, an appearance never seen with normal blood. The particles are composed of hæmatoblasts, surrounded by a finely granular or fibri lar substance, to which many leucocytes and red corpuscles adhere. The changes in the blood may be found, although in a less marked degree, in cases chronic, as well as in acute, inflammation.—*Lancet*, June 19, 1880.

Materia Medica and Therapeutics.

On the Physiological and Therapeutic Properties of the Alkaloids of the Pomegranate.

M. Dujardin-Beaumetz read a paper on this subject at the meeting of Paris Académie de Médecine on May 18, in which he postulated the follow conclusions: 1. The alkaloids of the pomegranates possess real and powe physiological properties. 2. These alkaloids induce paralysis of the motor ner whilst preserving intact muscular contractility. They do not attack sensibi and seem to strike the motor nerves at once in their muscular terminati They act like curare. 3. The sulphates of pelletierine and of isopelletie possess very active tænicide properties, and in doses of three centigrammes grains) in a solution containing half a gramme of tannin, they induce in the jority of cases (thirty-seven times out of thirty-nine, according to Dujar Beaumetz, and nineteen times out of nineteen, according to Laboullène), expulsion of the tænia with the head. 4. New attempts should be made to ap the physiological properties of these salts in the treatment of certain diseases; the first instance in those in which curare has already been indicated, as te and rabies; in ocular affections, in which it is necessary to induce active con tion; in the fundus of the eye; finally, in certain forms of vertigo, especially that of Menière's disease.—*London Med. Record*, June 15, 1880.

On Diuretics.

Dr. Maurel (*Bulletin Général de Thérapeutique*, March 30, 1880) has lat conducted a series of experiments on the action of certain of the most commo used diuretics, such as potassic nitrate, chlorate, acetate, and iodide, so salicylate, digitalis, colchicum, and squills, the latter in the form both of tinct and of oxymel. The experiments extended over a period of forty-six days, were undertaken on the same individuals. The general conclusions pointed great uncertainty in the diuretic action of all these medicines; the most act was potassic nitrate, which increased the solid constituents as much as ten cent. in the twenty-four hours. The other substances gave an increase of fr five to six per cent. only. Digitalis alone gave constant results upon the exc tion of water, which it notably augmented. The author believes that diure as a class, whether administered in health or in disease, have very little r power In many cases, the increased excretion which they apparently ind should rather be set down to other causes, such as changes in temperature, vous influences, or a "crisis" in certain morbid states. The real proof of er of diuretics would lie in their augmenting the urine at periods when it was rally suppressed, such as in the early febrile stage of many affections; but, ed by this test, all his experiments point to their being practically ineffica- .—*London Med. Record*, June 15, 1880.

Peptones.

BERGERON writes in *L' Union Médicale* of June 5th, that he has been experi- ing with peptones. He has lately had under his care an ill-nourished child years old, of whom the mother was thirty-five years old, and the father ed undeniable traces of scrofula. When M. Bergeron saw this child for the ime, she was confined to bed, exhausted by a fetid and constant diarrhœa. ower limbs were affected by lymphangitis. The lungs were not affected; I. Bergeron suspected fatty degeneration of the liver and kidneys. He put ild on an exclusively milk diet. The stools, which still remained frequent, ed a disagreeable smell. The child's weight varied from 9 to 8.9 kilo- nes (about 19 lbs.). He attempted to stimulate this frail organism by the aid oholics, which sometimes almost intoxicated the child. He then decided to er peptones, of which she took at first a teaspoonful night and morning in increasing the dose to four teaspoonfuls a day. She took this nourishment ut any difficulty. At the commencement of the trial, she weighed 8.90 ammes; ten days later on, she had gained 500 grammes. The diarrhœa be said to be stopped. Ten days later on, the weight remained the same. g that time, the child had been troubled by the eruption of two molar teeth, y a slight recurrence of diarrhœa. In another ten days, she had gained 600 nes, and then weighed 10 kilogrammes (22 lbs.). After the first week of gimen, the little patient had left her bed, and her features regained vivacity xpression. In another case, an adult had been bed-ridden for two years, ad been treated for cancer and stricture of the cardia; which, however, rgeron believed to be chronic gastritis with dilatation. This patient had erable depression of strength, continual vomiting of glairy matters, inter- t epigastric pain, retracted abdomen, notable emaciation, obstinate consti- , and eructations. The tongue was normal. Every kind of drug having ried in vain, M. Bergeron gave peptones in doses of three spoonfuls daily form of an injection, and as many by the mouth. After the tenth dose, tient was able to get up and walk with crutches. The dose was afterwards ssively increased, and she was able to walk in the garden, dispensing with utches. This form of treatment is still being continued, and M. Bergeron opes of obtaining a complete cure. He was particularly struck, in the use s regimen, with the consequent renewal of appetite, especially when the ne was administered in a little broth in the morning before the patient had n her fast. He believes that peptone should not be considered as a direct gen, but rather as a nourishment, which, once received into the stomach, is y absorbed, and leaves this organ aroused to the work of digestion without g any material for the function. M. Bergeron relates another case, of a us and anæmic young woman who complained of disgust for food. He tried , bitters, and nux vomica, without any result. Quite tired of her incessant laints, M. Bergeron at last advised her to take every morning, fasting, a oonful of peptone in a glass of Malaga, as she could not take beef-tea. She enced the treatment the next day, and in an hour she had an excellent ite, and expressed herself as being obliged to take something. She was so hted with the result, that she never failed to take a teaspoonful of peptone in le Malaga wine an hour before every meal.—*British Med. Journal*, June 880.

Therapeutic Use of the Pancreas.

All attempts to utilize in a therapeutic sense the very active properties of th pancreatic juice have hitherto failed. This want of success, according to ENGE SER (*Deutsches Archiv für Klin. Med.*, Band xxiv. p. 539, and *Gazette He domadaire*), is owing to the necessity by a natural tendency of first isolating t ferments, in order to administer them afterwards in the pure form. These i lated ferments being destroyed by the pepsine of the stomach in normal dige tion, the only field left for their use is the very limited one of the large intestin The pancreatic parenchyma, or even the fresh watery extract, on the contrary retains its digestive properties whilst passing through the stomach. This poin though difficult to explain, is supported by numerous observations and experi ments. Unfortunately, patients take the pancreas cut into small pieces, pounded and passed through a sieve, with the greatest repugnance. To av this serious drawback, since the use of the pancreas should be greatly prolong the author has had many preparations made. He finally settled on the follow method. The gland, cut in small pieces, was reduced *in vacuo* at 104° Fahr. an extract, then treated during forty-eight hours by absolute alcohol, which afterwards carefully evaporated. A coarse, light brown, highly hygroscopic pow is thus obtained, which patients take without disgust, and which possesses all qualities of the fresh watery extract. If clinical observations be consulted will be found that the action of the pancreatic juice is clear enough, but that indications for it remain very limited up to the present time. Fles published 1864 the case of a diabetic patient, who ate a great deal of meat and fat, and whose stools a quantity of fatty matter and muscular tissue were found in an changed condition. The use of the pancreatic juice caused these undige fragments to disappear immediately, and they reappeared directly the adm tration of the drug was left off. This remarkable observation may be consid as a type of the circumstances in which the pancreatic parenchyma may be fully employed. Engesser has obtained good results in cases of acid dyspep dilatation of the stomach, nervous dyspepsia, etc., whenever the presence of digested muscular fibres is detected in the egesta. The use of pancreatic j has in every instance removed these fragments, but produced very slight impro ment in these essentially chronic diseases.—*Lond. Med. Record*, June 15, 1

Phosphate of Bismuth.

M. TEDENAT (*Montpellier Médical*, July 1879, p. 83) recommends the ployment of phosphate of bismuth, which he prefers to the nitrate. The diarrhœal action of phosphate of bismuth is manifested in the same way as subnitrate. In consequence, however, of its greater insolubility, the phosp acts in rather weaker doses, especially in gastric affections. Notwithstanding acidity of the gastric fluids, it is not in the slightest degree affected, which is natural, since it resists strong acids, even in a concentrated form. The p phate acts in somewhat smaller doses than the subnitrate, and the difference activity is sufficiently great to create a superiority from this point of view favour of the phosphate. The doses are likewise varied, according to the na of the case. They are usually about from one to two grammes. The mode administration is absolutely identical with that of the subnitrate. With inf it suffices to place the desired quantity on the tongue, and to offer the breast the bottle. The salt is easily conveyed into the stomach, and it is possible this means to administer large doses. Adults take this drug suspended in s liquid. In many cases some advantage is found in making it into sweetmeats pastilles of about one to two grammes. They become disintegrated in th, and the phosphate is gradually conveyed into the stomach without the ent having been able to perceive the presence of an insoluble salt in the th. The phosphate finds its application in all the diseases in which the use he subnitrate is indicated. It is preferable to it in every case, on account of omewhat greater activity, and especially in affections in which the reconstit- effect, due to the absorption of phosphoric acid, finds its indication.—*Lond.* *. Record*, June 15, 1880.

Medicine.

Dietetic Treatment of Cancer.

rof. **Beneke**, of Marburg (*Berlin Klin. Wochenschrift*, No. 2, 1880), re- s a former suggestion of his, to the effect that by dieting patients with cancer, especially those suffering from its soft forms, with food from which the albu- tes, the alkaline and the earthy phosphates are to a great extent excluded, n may be done to check the abnormal cell-proliferation, and prolong, if not the patients' lives. He assumes that cancer-cells are relatively rich in a-stearin, leathin, and the above-mentioned phosphates, and the great source ese is animal food. Hence Dr. Beneke's cancer-diet allows only fifty grammes ely two ounces) of meat, weighed before cooking, *per diem*, supplemented a little fish in the form of anchovies, *sardines a l'huile*, or fresh herrings. er, sugar, rice, sago, potatoes, cream, nearly all kinds of fruit and green tables, are allowed, but bread is given sparingly or replaced by biscuits in ed quantity, and milk is excluded. As drinks, black tea with cream, cocoa, Moselle or Rhine wines, and occasionally champagne, are allowed. Beer, g to its richness in alkaline phosphates, must only be sparingly taken. Pro- r Beneke gives a diet-table for each meal in the day, the details of which we not space to insert. He calculates that by following his rules the normal of the nitrogenous to the non-nitrogenous constituents in ordinary mixed diet mely, 1 : 5—can be reduced to 1 : 8 or 9. The potassium salts also enter the chiefly as vegetable combinations, and not as phosphates, and the alkalinity he blood-serum is thereby increased so as more nearly to resemble its condi- in the herbivora, in whom Professor Beneke remarks, cancer is very rare. nswer to the possible question, "Can a man exist on a diet so deficient in gen and phosphates?" he quotes the *ipsissima verba* of several patients in ffirmative. One of these, an Englishman (affected, however, not with can- but with rheumatoid arthritis), has persevered in it for six years, with gain eight and muscular force, as well also, according to his own statement, of tal vigour. As to the practical value of the method there is at present little to aid. Professor Beneke can muster only eight cases it which it has been l—five by Esmarch and Oldekop, and three by himself. Two of the five too far advanced for operation, and soon died; two others also died after ral operations. The fifth—a simple cancer of the breast, which was also ted with liquor arsenicalis—was operated on without relapse. Beneke's own e cases were all alive at the last report. It would be easy to try the diet on rge scale either at the Cancer Hospital or in the cancer wards of the Middle- Hospital, but as Beneke insists, it must be strictly carried out, and the theo- cal principles on which it is founded must be steadily kept in view by the sur- n in charge. To those patients who require more fat than is prescribed in the t-table, and who cannot tolerate butter, cod's oil may be given. Those in- ed to corpulence should take small doses of Carlsbad salts regularly during the "cure." In conclusion, Beneke points out that if, as is probable, the cancerous and the scrofulous diathesis are in many ways diametrically opposed to each other, what his dietetic system seeks is to reduce the former to the latter.—*Med. Times and Gaz.*, June 26, 1880.

—

Disinfection of the Stools in Typhoid Fever by Charcoal.

M. Maurel, a naval surgeon, stated at the Therapeutical Society (*Lyo Méd.*, May 23) that the fetid stools in typhoid fever are easily disinfected by administering one and a half or two grammes of Belloc's charcoal. The absorption of putrid matters is obviated, and the favourable issue of intestinal ulceration is assured. The charcoal may even destroy the infectious agent, and i suppresses the fetid odour of the stools. Dr. Guéneau de Mussy observed tha for the prevention of auto-infection Chomel was in the habit of giving chlorid of lime in typhoid cases, and that he himself has for a long time past administere for the same object salicylic acid in rice-water, sometimes adding a little lemo juice. M. Constantin Paul, in imitation of Polli, administers the hyposulphi of soda in enemata when the intestine is gravely affected, using them cold i typhoid fever, and tepid in dysentery. As to the action of charcoal, judgi from the fact that when it gains admission to the lungs it sometimes causes chron pneumonia, he fears that it might cause too much irritation of the Peyeria patches; it does not combat flatulence as an absorbent, but as a stimulant, r storing their vitality to the tissues and exciting them to fulfil their functio M. Grellety observed that Dr. Bouchard gives a tablespoonful of charcoal eve three hours. The fetid odour disappears, and neither hemorrhage nor oth accident is produced. The statistical results of this treatment are very favo able.—*Med. Times and Gazette*, June 12, 1880.

—

Local Antiseptic Treatment of Smallpox.

Dr. Ernst Schwimmer, of Buda-Pesth (*Deutsche Medicin. Wochenschrif* May 8th), having obtained no result from the internal administration of carbol acid, salicylic acid, and thymol in smallpox, has tried the external use of carbol acid and thymol. The formulæ which he employed were the following; a so paste being made in each case. 1. Carbolic acid, 4 to 10 parts; olive oil, 40 parts; finely powdered prepared chalk, 60 parts. 2. Carbolic acid, 5 parts; olive o very pure starch, of each 40 parts. 3. Thymol, 2 parts; linseed oil, 40 parts; prepared chalk, 60 parts. His principal object was to prevent the disfigureme of the face as much as possible. For this purpose, when the patients were ad mitted into hospital and the presence of an eruption of intense or confluent variol on the face was ascertained, the paste was applied to the parts on a linen mask, in which openings were cut for the eyes, nose, and mouth. The greatest amoun of success was obtained from the paste No. 1, which was used in 177 cases. Un der its use, the drying of the pustules took place some days earlier than usual and in several cases no great amount of suppuration occurred on the face. That it was the carbolic acid which produced this favourable result, the author con siders proved, not only by the fact that other ointments had been used on previous occasions without effect, but also by the circumstance that carbolic acid could be detected in the developed pustules after the paste had been applied four days, and that the urine gave the characteristic reaction of carbolic acid. Dr. Schwimmer strongly recommends the local application of carbolic acid in variola. —*British Med. Journal*, June 12, 1880.

Hœmophilia.

r. **Zielewicz**, of Posen, relates in the *Centralblatt für Chirurgie*, for April
he following interesting case: An anæmic lad, eleven years of age, was
ght into the Children's Hospital on January 2, on account of an injury to the
knee, caused about a month before by a fall. He continued to go to school
the accident, until the increasing pain and swelling obliged him to be con-
to bed. The circumference of the knee was thirty-five centimetres, that of
eft being twenty-seven, and the patella was almost immovable. There was a
contraction of the knee, and the muscular substance of this limb was feebler
that of the other. On examination, under anæsthetics, only an indistinct
ation could be perceived, the sensation conveyed being almost that of a
hy substance. By means of a Pravaz's syringe, some clear fluid blood was
drawn. The joint was firmly inclosed in a plaster-of-Paris bandage, which
d no pain whatever. On January 19, this was removed, and almost imme-
ly there was produced in the knee, which during the treatment had continued
nged, such dreadful pain that the hitherto apathetic and patient child tossed
the bed like one mad. The tongue was dry, and the temperature in the
ng was 37.7° C. In spite of morphia injections, and painting the joint with
orm, the condition of things remained much the same until the 21st. The
now measured thirty-three centimetres, and was very painful to the touch.
oy was very restless, with a temperature of 38.3°. C.

tton-hole apertures were now made, under carbolic acid spray, at the lowest
of the joint, on each side of the patella; and blood spouting out of the open-
irrigations with acetate of alumina were resorted to, with the apparent effect
resting the bleeding. On the finger being introduced, it was ascertained
he joint was filled with coagulated blood, which adhered pretty firmly to the
le. In order to facilitate the removal of the coagula from the upper portion
joint, an aperture was made there also; and elastic drainage-tubes having
introduced, active irrigation with the acetate was kept up until the joint had
ne entirely freed of coagula, and the bleeding, which during the operation
ontinued to diminish, only continued trickling from one of the lateral open-
A compressing bandage was then applied.

lled to the patient two hours afterwards, the reporter found him and the bed
lated with blood, alarming collapse having set in. On the removal of the
ge, the entire joint, drainage-tubes, and apertures were filled with coagu-
blood, fluid blood also trickling away. Digital compression of the femoral
and various other means were tried in vain, the boy dying twenty hours
the operation.

examination after death, the joint was found filled with loose coagula, in
floating in fluid blood, and in part adhering to the walls of the capsule. The
ents were uninjured, and no laceration of the capsule had taken place. The
teal vessels were in an entirely normal condition.

though no anatomical cause of death was here discoverable, it was afterwards
tained that the boy had formerly bled for three weeks after having had a
drawn, and had never been properly himself since. The peculiarity of the
consisted, therefore, in the occurrence of a traumatic injury to the joint in a
ct of constitutional hemorrhage. This condition of hæmophilia explains how
s that this effusion of blood existed without either undergoing absorption or
g rise to suppuration.

fter relating to the Vienna Doctoren-Collegium (*Allg. Wien. Med. Zeit.*,
il 13) some cases of hæmophilia which had occurred in his practice, Dr.
tzka adverted to the principal facts connected with this disease. The Ger-

manic race, it would seem, is especially liable to it, for while, in 219 families di
posed to hæmophilia mentioned by Immerman, 119 belonged to England, Ge
many, or North America, only 50 were French, Russians, Swedes, etc.; and
case is known to have occurred in Italy. Jewish families seem to be especial
liable to it. It is a general congenital diathesis, which may or may not be here
itary, occurring very much more frequently in males than in females, so that
650 cases 602 were males and 48 females. But the female members of bleedi
families, even when they are not "bleeders" themselves, are more dangero
because they keep up the hereditary disposition; while in the men of such fa
lies who have not been bleeders this hardly ever occurs.

The first hemorrhage is observed during the first or second year in about 70 p
cent. of the whole number; and although hemorrhage may occur later, it
never been met with in a well-marked case of hæmophilia for the first time af
the twenty-second year. Rudimentary forms of the disease may occur at a la
period. The fertility of bleeding families is great, so that Grandidier coun
442 children in forty-five families, and Wachsmuth 114 in 12 families.

The affection is usually hereditary, and its subjects are generally fair with b
eyes, having a delicate, pale skin. The bleeding in hæmophilia may be eit
traumatic or spontaneous; and both of these may be either superficial or int
stitial. In the traumatic cases the bleeding usually, but not always, immediat
succeeds the injury; and in one case, in which the external skin, to all appe
ance, was uninjured, violent hemorrhage occurred in half an hour. Freque
the slightest injuries give rise to severe hemorrhage, while large wounds are so
times unattended with ill effects. Incision of the frænum linguæ has pro
fatal, and the cases in which death has followed ritual circumcision are ra
numerous; and even vaccination has been attended with serious hemorrh
Extraction of teeth has given rise to most dangerous bleeding; and Dr. Hert
alludes to the case of a boy, whose brother had died in consequence of circ
cision, and who bled for eight days after the extraction of a tooth. Spontane
hæmophilia usually appears at a later period than the traumatic. Bleeding fr
the nasal membrane and the skin occupy the first place, the hemorrhage un
the skin varying in size from that of a pea to that of a man's hand. These
travasations usually soon disappear again. Bleeding from the stomach, intesti
canal, kidneys, and other organs, is of rarer occurrence. Pseudo-rheumatic p
and swellings of the joints are not an uncommon accompaniment of hæmophili

The affection usually lasts for the life of the individual, and the duration of
different attacks varies from some hours to days, or even weeks. It usua
proves fatal, for Grandidier, of 212 subjects of hæmophilia, found only 101
had reached their eighth, and only twenty-four who had reached their twe
second year. Instances, however, are known of their having reached their
tieth year.

The prognosis is more unfavourable the earlier the disease has appeared;
when a child has reached its eighth year, less uneasiness may be felt about
although the danger of a recurrence of the hemorrhage must never be underra
Superficial bleeding is more unfavourable than interstitial, and internal is
dangerous than external.

The prophylaxis is of importance, both with regard to preventing the prod
tion of new cases and to lessening the number of attacks in those who have
hibited the disposition. Thus, among the members of bleeding families, or w
hæmophilia is suspected, all wounds, even the slightest, and injuries, and
especially tooth-drawing and circumcision, must be absolutely avoided; while
the anæmic, iodine, iron, and strengthening food should be habitually employ

in the plethoric, cold applications, acetate of lead, and ergot. Alcohol, hot
ks, and excessive bodily exertion are mischievous.
treating these cases the hemorrhage must be arrested as soon as possible,
ting the advice of those who recommend that in the plethoric time should be
for the pulse to diminish in force. Seeing the difficulty there so often is in
ng the blood, any delay, especially in children, is most dangerous.—*Med.*
s and Gazette, June 26, 1880.

Drugs in Epilepsy.

the annual report of the Derby County Lunatic Asylum which has just been
shed, Dr. **Murray Lindsay** records the results obtained from the admin-
ion of certain drugs—sumbul, bromide of potassium, zinc, arsenic, nitrite of
, and nitro-glycerin—to a group of confirmed epileptics. The trials made of
drugs have not been sufficiently numerous nor long continued to warrant
lefinite conclusions, but they have certainly afforded some interesting and
stive results, and must encourage to further experiment. As might have
anticipated, Dr. Murray Lindsay has found that bromide of potassium is
emedy from which benefit is most surely and generally derived in chronic
ptics, and by which the frequency and severity of the fits is most certainly
nished. But, while according to this remedy the first place in the *rôle* of
cines useful in epilepsy, he assigns positions of subordinate but still material
lness to nitrite of amyl and nitro-glycerin. The latter drug has not before
tried in epilepsy, and much interest therefore attaches to the provisional
usion of Dr. Murray Lindsay and his colleague Dr. Thompson respecting it,
while in some cases it decidedly aggravated the malady and increased the
er of fits, in other cases—those in which there was marked anæmia—it con-
d benefit and diminished the frequency and severity of the seizures. It was
nistered in doses of from one to ten minims of a one per cent. solution, and
pushed in some cases until its physiological effects, quickening of the pulse
hrobbing of the arteries, were established. Even when taken continuously
hree months, it had no ill effects upon the general health. Nitrite of amyl
r. Murray Lindsay thinks, most useful when bromide of potassium fails to
From sumbul, arsenic, and zinc, he obtained no appreciable effects.—
ish Med. Journal, June 12, 1880.

Hysteria in Children.

r. H. **Paris** has written a thesis on this subject (Paris, March, 1880, and
nal de Thérapeutique, 10th May). Notwithstanding the almost universal
ce regarding hysteria on the part of pathologists who have concerned them-
s with the diseases of childhood, it is quite certain that a number of very
g girls suffer from this affection. Out of 430 cases recorded by Briquet,
eria was developed in childhood; that is to say, up to twelve years of age,
period when puberty commences. Hysteria in young girls is caused by
holism, epilepsy, and even phthisis in the parents; by chlorosis, moral
bles, and bad treatment. With regard to its treatment, if left to itself,
s no tendency to improve; prophylactic treatment is the most efficacious,
should consist in a sensible education, of which the objects may thus be
ned: to develop the physical side, and to avoid precocious development,
er of intellectual or of emotional faculties. Country life, very simple habits,
ks, and active games are indicated. The children should be kept up by a
ic regimen, quinine, and iron. Amongst the more special agents, the most
cacious are bromide of potassium and arsenic; the first in doses of from two

to six grammes (30 to 90 grains); the second in the form of Fowler's solutio, of which the daily dose, easily tolerated by children, may be as large as te drops, given in divided quantities. Surprising results are often obtained wit hydrotherapy in its various forms, prolonged warm baths, cold baths, cold appli cations, and especially spray and shower baths.—*London Med. Record*, Ju 15, 1880.

Laryngeal Chorea.

Dr. SCHRÖTTER, in the *Allgemeine Wiener Medizinische Zeitung*, No. 7, give this name to a class of cases characterized by a peculiar barking or crowing cough over which the patient has no control, and which is totally different from th observed in other affections of the air passages. In certain cases of hysteri such a cough may occur, and it is occasionally simulated; but in many instanc it cannot be attributed to either of these causes. That this affection is of t nature of chorea, Schrötter believes from the following: 1. The patient has control over the attacks. 2. The spasmodic contractions disappear during slee 3. Other muscles, not connected with the larynx, are occasionally also affect in persons thus attacked. 4. Other nervous affections may manifest themselv in the same person or family. 5. The relapses are frequent. Eleven cases hav come under his notice; most of them were children between the ages of 8 and 1 He believes the affection is a motor neurosis, but thinks there is no proof of i originating in the central nervous system. The treatment consisted in the co shower-bath, quinine in large doses, tonics, iron to anæmic persons, and the a plication of the constant current.

M. MASSEI, in the *International Journal of the Medical Sciences*, of Napl writes to object to the term laryngeal chorea, as applied by Schrötter to the cl of cases described in the paper of which the foregoing is an abstract. Dr. M sei considers the affection due to a hyperæsthesia of the reflex sensibility of t larynx. He argues as follows: If the mucous membrane of the larynx b slightly acted upon, the only effect produced will be the excitation of the exp ratory muscles, and a convulsive movement, ushered in by a cough; while in ration, difficult at first, will soon become normal. If, on the other hand, th mucous membrane be acted upon by strong excitants, convulsive occlusion fo lows, ushered in by more or less prolonged and sonorous inspiration. In bo these cases the nerve-terminations receiving the impression are the same; th mode only in which they respond is different. We have a right, then, to disti guish "common" or "reflex sensibility" from "general sensibility." Chore movement then, is a constant consequence of the morbid excitation of the sens bility of the mucous membrane. This being so, why should we call that specia sonorous, short, very frequent cough, laryngeal chorea, and not apply the sam term to spasm of the glottis, since either may be produced according to the d gree of excitation?—*London Med. Record*, June 15, 1880.

Diagnosis between Syphilis and Laryngeal Phthisis.

MOURE (*Annales des Maladies de l'Oreille et du Larynx*, Feb. 1880) compare the symptoms of these affections at different periods: 1. The early stages of lary geal phthisis with secondary syphilis; 2. The ulcerative stages of laryngea phthisis with tertiary syphilis. The principal symptoms which he passes in re view are those furnished by the voice, cough, expectoration, pain, respiration, enlargement of the glands, and local appearance of the disease. In the secondary period of syphilitic laryngitis the voice may be normal or hoarse; in the tertiary rarely aphonic, but always hoarse. In early tuberculosis the voice is husky, ere may sometimes be aphonia; in the ulcerative stage, aphonia is always . In secondary syphilis there is no cough: it is also rare in the tertiary out is very frequent in the ulcerative period of laryngeal phthisis. There pectoration in secondary syphilis; but it is present, and may be blood- and purulent, in the tertiary. In commencing laryngeal phthisis it is , and in the ulcerative period muco-purulent. The pain is nocturnal in . The cervical and submaxillary glands usually swell in syphilis, whereas rculosis they do not enlarge, but often atrophy. Both affections show mia of the mucous membrane: in phthisis it affects the arytenoid region, roseate in colour; in syphilis it affects the front part or the free edge of l cords, and in colour is dark red. The mucous patches of syphilis pro- ve the mucous membrane, are depressed at their centres, and are sur- l by inflammatory redness. Tuberculous erosions, though gray like the patches, differ in not projecting above the level of the mucous membrane; ges are confused and irregular. Gummata are apt to be mistaken for s, and syphilitic for tuberculous ulceration. Gummata are large and and cause projections under the mucous membrane: tubercles are gray, and small, and give a granular appearance to the mucous membrane. ta affect chiefly the epiglottis, the glottic portion of the larynx, and the ; tubercles appear most often on the subglottic portion of the arytenoid es. The ulcers in syphilis are solitary or few in number, their edges are d and cut perpendicularly; in tuberculosis they are oval or round, with l edges, often covered with fleshy granulations or polypoid vegetations. cerations affect the epiglottis, but differ in their mode of evolution. In they proceed from below upwards, and from the periphery to the centre; ilis the process is reversed. The affection can always be arrested in ; this is impossible in tuberculosis, especially if the ulcerative stage have ached.—*London Med. Record*, June 15, 1880.

—

atment of the Acute Pneumonia of Adults by Digitalis and Alcohol.

LBERT JOLY (*Revue Médicale de Toulouse*, July, 1879, and *Bulletin l de Thérapeutique*, May 30) gives an account of the results obtained by ux in the military hospital at Toulouse, by the use of digitalis and alcohol reatment of pneumonia. He arrives at the following conclusions. 1. avity of either simple or double pneumonia, if uncomplicated, is *nil*, if nal evolution and its natural tendency to recovery be not disturbed by d medication. 2. Its affinity with the eruptive fevers (internal herpes of riters) seems to be confirmed by the very regular progress, of which the given by tracings. 3. Pneumonia is an essentially debilitating disease, h the temperature falls below the normal rate more than in any other natory disease. It evidently results that the chief indication is to combat bility, and to strengthen the organism by stimulants, notably by alcohol, s also an arrester of waste. Nevertheless, as the temperature, even by often constitutes a danger, it is necessary to anticipate it, not by vene- nor by tartar emetic, which agitate and weaken the patient, but by digi- ne advantageous effects of which cannot be denied. 4. Every fresh cause erthermia should be carefully avoided from the outset, and consequently g must not be allowed, as by the wound it produces and the accidents it on it raises the temperature in a notable way. 5. Pulmonary exudative on, which creates a danger by its abundance, must be carefully avoided; uently, opium, which favours it, must not be given. It also results that g must be avoided, as by immobilizing the chest it obstructs expectoration. These conclusions are, it is stated, confirmed by the consideration of th results obtained.—*London Med. Record*, June 15, 1880.

Tincture of Eucalyptus in Pulmonary Gangrene.

M. Raynaud, in a clinical lecture to his pupils at the Charité Hospit (*Journal de Médecine*, May, 1880), speaks strongly of the good effects of tin ture of eucalyptus in large doses in this affection. He referred specially to t case of a man who had been ill for three weeks, in whom the gangrene co menced as pneumonia. It soon became confirmed, and was followed by a ma fest cavern under the left clavicle. This patient was in a very serious conditi when he began to take the eucalyptus, but at the end of three days there was notable improvement. The man was aged 69, and recovered, with comple disappearance of the physical signs indicating the existence of a cavern. Anoth of M. Raynaud's patients, suffering from pulmonary gangrene, after having be operated on for cancer of the tongue, was cured of the gangrene by the influen of the same drug, and the operation also gave a satisfactory result. In the fi case, M. Raynaud intends to employ the tincture of eucalyptus in doses of fr six to eight grammes a day, and to join with it Trousseau's treatment, whi consists in inhalations of terebinthine. Inspiration is effected by means o tube inserted in a bottle of the essence.—*London Med. Record*, June 15, 18

Subphrenic Pyopneumothorax and Abscesses.

Under the name of subphrenic pyopneumothorax, Dr. E. Leyden describe the *Zeitschrift für Klinische Medicin*, Band I., cavities full of air and pus for beneath the diaphragm, and extending more or less into the thoracic cavity s to produce physical signs very closely resembling those of genuine pyopneu thorax. These abscesses may be formed either on the right or on the left s The mechanism of the origin of these air-containing suppurating cavities is clo connected with a history of perforative peritonitis; they are most frequently result of perforating ulcers of the stomach or duodenum. Their tendency, w left to themselves, is almost without exception towards death. It appears t they most frequently perforate the lung: but they may discharge in other wa Perforation of the stomach or of the transverse colon may end favourably. Leyden's observations have shown him that the diagnosis of subphrenic pyop mothorax may generally be made with certainty; and the diagnosis is of gr practical importance, as life may be saved by operation. The following are, cording to Leyden, the diagnostic characters of subphrenic pyopneumothorax. The development of the disease is preceded by symptoms of general (perforati peritonitis or discharge of pus by the bowel. 2. An exudation takes place in lower part of the thorax (right or left) with symptoms of inflammation: co and expectoration being absent, at least for a long time. 3. There are disti symptoms of pyopneumothorax in the lower part of the chest: viz., comp resonance on percussion as far as the border of the ribs, and dulness in the lo and posterior part: in this region the respiratory murmur and vocal fremitus absent, and metallic tinkling is heard on simultaneous auscultation and per sion: the succussion sound is distinct. 4. At the same time, examination sh that the lung above is unaffected, and that it descends during deep inspirati Beneath the clavicle, there is vesicular respiratory murmur; and the vocal f mitus reaches as far down as the fourth or fifth rib. On deeper inspiration, h ever, the normal respiratory murmur is heard as low down as the fourth or f rib; while at the same time all respiratory sound is sharply cut off below t limit. 5. The dulness on percussion, corresponding to the exudation, is rap

listinctly altered by changes in the position of the body; but the change is
ed to the lower part of the chest (*i. e.*, beneath the diaphragm). 6. The
of increased pressure in the pleural cavity are either absent or very indis-
The corresponding half of the thorax is scarcely distended, the heart is
ittle pushed aside. On the other hand, the liver reaches as low down as the
licus or even lower. 7. In the further progress of the case, any doubt that
have existed as to the diagnosis may be removed by the sudden and abun-
expectoration of ichorous pus, indicating perforation into the air-passages.
nally, the diagnosis may be confirmed by manometric examination of the
a. Pfuhl had already remarked, that, in puncture combined with the use
e manometer, when the canula is in a cavity beneath the diaphragm, inspi-
is attended with an increase, and expiration with a diminution of pressure;
the reverse of what occurs when the canula lies in the pleura.—*British*
Journal, June 12, 1880.

Case of Basic Cavity of the Lung treated by Paracentesis.

a late meeting of the Royal Medical and Chirurgical Society, Dr. R. Doug-
Powell and Dr. R. W. Lyell contributed a paper on a case of basic
of the lung treated by paracentesis. The case related was that of a man
forty-nine, of previous good health, but intemperate habits, who in Decem-
1878, had had bronchitis, followed in the ensuing February by pleuro-
nonia and fetid expectoration. He improved after a time, but relapsed
ly, and in August was admitted into the Middlesex Hospital under Dr.
ll's care. On admission, the physical signs showed consolidation of the
lobe of the right lung, with excavation of its central portion, the cavity
being centred about the level of the seventh dorsal spine in the line of the
of the scapula. There was considerable hectic, with diarrhœa and anorexia.
breath and expectoration were extremely fetid, the latter being muco-puru-
n character, and very abundant, amounting to about one pint in the twenty-
hours. The area of excavation having been carefully marked out, the ope-
of paracentesis was performed by Mr. Lyell on September 11. A medium-
aspiration-trocar was first thrust in at the eighth space mid-scapular line,
free incision having been made through the tissues down to the intercostal
brane, the fine trocar was withdrawn and a full-sized hydrocele trocar in-
d, which, after slightly enlarging the opening, was in its turn removed, and
ge drainage-tube introduced. Carbolized dressings were applied. A mode-
quantity of secretion escaped from the wound (which gave rise to no serious
ling), and the discharge subsequently from the tube, although free, was
r abundant. The expectoration and cough, however, at once almost entirely
d. The wound was dressed daily under the carbolic spray, with the view
isinfecting it and the cavity, and injections of Condy's solution were used.
October 2 there was some return of fetor of breath, that of the discharge from
tube having never been quite corrected. Some trouble was occasioned by
tube slipping out, its reintroduction being hindered by encroaching granula-
e, and the tube was felt to strike against some impediment deep in the lung.
channel was kept dilated, however, and the patient improved in strength,
on the 20th was transferred to the Brompton Hospital. Fetor of sputa re-
ed towards the end of the month, however, although the amount expectorated
inued to be very scanty. The patient lost ground rapidly, and was finally
ed with pleuro-pneumonia on the opposite side, of which he died on October
fifty days after the operation. The post-mortem examination revealed the
sence of several inter-communicating cavities in the lower lobe of the right
g. This lobe was firmly adherent throughout, and a drainage-tube, passing

through the eighth intercostal space, entered a contracted cavity, which was co nected with the main cavity by a short dilated bronchus. This small cavi must have been closely sub-pleural, and was the very lowest of the series, a though at so high a level as the eighth space and it was only separated from th diaphragm by one-eighth of an inch. It was evident that in contracting up the tube the wall of the cavity had come in contact with and partially occlud its extremity. The rest of the lobe was densely consolidated by fibroid grow surrounding bronchiectatic cavities. There was broncho-pneumonia and effu on the left side. The rest of the lungs were emphysematous. In their remar upon the case the authors commented upon the infrequency with which the b of the lung had been tapped, and pointed out, that the immediate cessation cough and expectoration after operation in this case was a fact very encouragi to future interference with such cavities under more favourable circumstanc and also afforded a valuable hint respecting the importance of disinfecting lu cavities. For it was clear from the small amount of the discharge, compar with the great previous quantity of expectoration, that the bulk of that expe ration had been yielded by the bronchi irritated by the acrid fluids and gases their passage from the cavities. Whilst advocating the puncture of chronic b cavities in suitable cases, the authors deprecated interference with apex caviti on the ground of its being rarely necessary or useful, and are averse save in e ceptional instances to making incisions into acute basis abscesses of the lung. the present case, however, the operation had undoubtedly been postponed t long, the patient having come under observation too late. The diagnosis of t case from empyema was touched upon, and the several steps of the operati discussed; the use of a large trocar in preference to the knife being advocat In future cases, too, the authors would prefer to choose the centre of the cavi rather than its lowest point for puncture, where it is situated in the poste lobe of the lung.

Dr. **Symes Thompson** thought the operation advantageous in selected ca but it did not suit where the disease was acute or where the pleura was not herent. When the inflammation was of a gangrenous character, or where t patient's health was very bad, it might be performed, but not, he thought, u recovery by any other procedure was nearly hopeless. There would always great difficulties as to diagnosis, for to be successful the putrid cavity must near the surface, and these cases are not very numerous nor easy to make out.

Dr. **Barlow** said that no treatment of suppurating cavities could be satisf tory without good drainage. In the case narrated the opening was sinuous, hence the drainage could not be very good. He would make a double openi as in empyema. It was easier to get the cavity cleaned out in this way. empyema he fixed the tube by a thread round the body.

Dr. **Theodore Williams** thought the operation might be useful in cert forms of bronchiectasis, but these could not easily be reached. The removal the putrid fluid was all-important, as the other lung might be poisoned by t exhalations. In one case he tapped a limited empyema, thinking it a bronc ectasis. In most cases of phthisis, the cavities, being in the upper part of t lung, drain themselves. He referred specially to a case where the President h operated for him with very great advantage.

Dr. **Reginald Thompson** thought that the operation should really be co sidered as a means of preventing septic influences on the other lung, and shou therefore be undertaken as soon as possible. There was often rapid break-dow of one lung, and then the other became infiltrated by inhalation with its product

Mr. **Erichsen** said that in these cases the great thing was drainage, and that antiseptics did little or no good. The patient was really poisoned by his own

ions. He would make a free opening and get rid of the foul material. In
se referred to by Dr. Theodore Williams the whole house was infected, and
nell could be perceived to the very door, yet when the collection of stuff
pened the whole fetor rapidly disappeared. Care should always be exer-
in the selection of a tube; they should be rigid, to obviate any risk of
ng an acute angle. He had found a flat trocar with a vulcanite canula the
strument to use, but if he had to do it again, he would rather pass in a
or, and then gradually tear with dressing-forceps, than cut. Injection of
nly seemed to irritate. In Dr. Williams's case an emphysema set in all
he body, and at each cough it could be seen to increase. This air, although
ely fetid, produced no bad effects on the body.

Holmes, with regard to the last point, mentioned a case of emphysema
cted with the rectum, but neither here was there any damage to the tissue
he foul air.

Powels, in reply, said there was a difficulty as to the time of the forma-
f the various cavities; perhaps one formed first, and the others were
ary. He did not favour the idea of a double opening. Only a small
ty of fluid was removed, yet the expectoration ceased at once, perhaps
to cessation of the irritation to the bronchi.

Lyell said that in another case he would prefer a metal tube.—*Med.
and Gazette*, June 19, 1880.

Treatment of Dextral Valvular Disease of the Heart.

Alexander Morison, in a graduation thesis on disease of the valves of
ht side of the heart, thus sums up his therapeutic conclusions (*Edinburgh
al Journal*, March, 1880). 1. A more or less orthopnœic position is best
to many cases of organic valvular disease of the dextral valves; but there
ceptions to this rule, and the latter will probably most frequently be con-
d by cases of pulmonary valvular lesion, and especially by cases of pure
nary regurgitation, just as we find a recumbent position best adapted to the
ous instances of aortic regurgitation. 2. The cutaneous circulation must
intained by adequate warmth, and arterialization of the blood by as free a
tion as is compatible with the maintenance of sufficient heat. 3. Food
e given to patients from dextral disease under the same restrictions as in
e of other cardiac sufferers, but fibrinogenous material must be even less
ned than in other cases, from the greater liability to spontaneous coagula-
nd alcohol in one form or another is absolutely necessary, but must be
usly administered. 4. Venesection is calculated to render signally good
e in the retrograde plethora due to dextral valve lesions. 5. External
ations must be employed in such cases under the same circumstances as in
forms of cardiac disease. 6. The use of ammonia, from properties pecu-
it, is indicated, but asphyxial conditions may render its combination with
te of potash or some other oxygenator advisable. 7. The employment
italis is not only useless in cases of organic disease of the dextral valves,
aught with a danger which cannot be exaggerated, and the chief cause of
rnicious influence is probably its systolic action upon the left ventricle.
functional valvular disease of the right heart, arising from ventricular dila-
, and especially in functional tricuspid regurgitation, digitalis carefully ad-
tered may prove very beneficial, by diminishing the capacity of the ventricle,
estoring or improving the competency of valvular action.—*Lond. Med.
rd*, June 15, 1880.

Salicylate of Sodium in Acute Rheumatism.

A. DIERSTERWEG (*Deutsche Med. Wochenschrift*, No. 43, 1879, and *Centrel-blatt für die Med. Wissen.*, January, 1880) reports one hundred cases treat with this remedy. Of these, the disease was cut short in thirty-six in twen four hours, in eighty-five in forty-eight hours, in ninety-eight in seventy-t hours, in one in eighty-four hours, and one, a girl, aged 20, was uninfluence The amount of medicine taken was in forty-six cases 5 to 15 grammes (77 231 grains); in forty-one cases, 20 to 28 grammes (308 to 432 grains); and twelve cases, 30 to 40 grammes (463 to 616 grains). In three of the cases c short (all females) suppurative arthritis followed in the ankle, which was cur by incision and drainage. Relapses occurred during the use of the medicine eleven cases, four in the first week and four in the second. Cardiac complic tions occurred only five times (and of these three had had heart disease befo in one hundred cases and twenty relapses. .Pleuritis occurred three times. one of these cases the patient had pericarditis on admission to the hospital. B yond this, the course of the complications under treatment by salicylic acid w favourable.—*London Med. Record*, June 15, 1880.

Occlusion of the Coronary Arteries.

The arrest of the blood-supply to the walls of the heart, in consequence of d ease in the coronary arteries, is a well-known pathological factor in certain m bid states of the heart's walls. The effect of such arrest has been studied exp mentally by several investigators, who found that it caused rapid enfeeblement the heart's action. Lately the subject has been reinvestigated by GRUNHAG and SAMUELSON, who have ascertained new facts. By keeping rabbits u the influence of curara and artificial respiration, they were able to compress coronary arteries by means of forceps, and to do this repeatedly, so as to obs the comparative effect of arrest and renewal of the flow of blood. The comp sion caused at once a retardation of the rhythmical action of the heart, especi of the left ventricle, while the contractions of the right ventricle were at first m rapid, and then were also slowly retarded. The slowing of the action incre the longer the compression lasts, or after several repetitions, until finally the c tractions cease, first of the left, and later of the right ventricle. A second ef of the compression is weakening of the heart's contractions. This was also served and estimated by the manometer by Bezold, and it was corroborated Samuelson with a galvanoscopic frog. As soon as the heart became pale and contractions were less frequent, these were no longer sufficiently powerful to cite the sciatic nerve of the frog, but after the current of blood was renewed, nerve again responded. This experiment was repeated several times in the sa animal. A third fact noted was that the compression of the left coronary art caused a gradual swelling of the left auricle, which was distended until it peared like a bright-red, shining bladder, its rhythmical contraction lessening an oscillating movement, which finally ceased. This phenomenon was obser when the left ventricle was weakened, and its action retarded, while the ri auricle and ventricle continued to contract strongly. As soon as the compress was stopped, and the left ventricle began again to contract, the distended auri emptied itself in one to two minutes, and both series of the heart were again uniform action. This phenomenon constitutes a striking illustration of the chanism by which obstruction at the mitral orifice or weakness of the left ven cle leads to auricular dilatation, and to œdema of the lungs.—*Lancet*, June 1880.

Peritonitis Appendicularis.

n essay, of which a summary is given in the *Nordiskt Medicinskt Arkiv,* xii., Häft 1, Dr. WITH describes, under the name of peritonitis appendicu- he form of peritonitis produced by ulceration and perforation of the vermi- ppendix.

well know that the vermiform process is often the seat of catarrh and ion, frequently produced by abnormal contents, hard fecal masses, or bodies. In like manner, the pathological conditions thereby caused are ized as adhesive peritonitis when the ulceration approaches the surface of wel, or ulceration through the bowel with local or general peritonitis; an may also be formed about the bowel, and may burst in various directions. attention is paid clinically to the affections of this portion of the intestines, ey are most frequently grouped under the comprehensive title of "perity- " which has gradually come to include all inflammations of the right iliac While the most severe cases, in which there are suddenly developed signs eral peritonitis proceeding from the appendix vermiformis, are most fre- correctly diagnosed and treated, those cases which run a more chronic attended with tenderness and swelling in the right iliac fossa, are, accord- Dr. With, not treated yet with sufficient care, inasmuch as purgatives are stered early, although the proper object is to overcome the peristaltic as much as possible, and allow time for adhesive peritonitis to take place. any cases, ulceration in the appendix vermiformis is indicated by severe the abdomen, especially low down and to the right. The cases are gene- ipposed to be ordinary colic, and recovery takes place after a few days' ment to bed and expectant treatment. In support of his assertions, the refers to necropsies. Toft found, in 300 *post-mortem* examinations, the lix vermiformis sound in only 190, and more or less diseased in 110. Dr. imself has seen a few cases of general peritonitis following perforation of miform appendix, the diagnosis being confirmed by necropsy. He relates tories of ten cases of this kind, which in their essential features present a esemblance. Young powerful individuals are attacked without any pre- ndisposition, with violent pains in the abdomen, generally most severe on ht side, nausea, eructation, and vomiting; the vomited matters being at soon afterwards of a green colour. There is high fever; the abdomen ler and distended, and often becomes hard, and the distension most fre- y continues to increase. The pain and tenderness sometimes diminish, ay continue increasing in severity to the last. The vomiting generally ies. For a day before death, there is sometimes a certain amount of *ia,* with mild delirium; there is usually constipation. In only three of es was the illness preceded by indisposition of from one to fourteen days' on; in the remainder it set in suddenly. The starting point of the pain not always be determined with certainty; at one time it seemed to start he cardia, at another from the umbilicus or the left hypogastrium, but requently it was traceable to the right iliac fossa. In nearly all the cases, ta and purgatives were given either at the beginning, or in the course of ness.

ontrast with these, the author relates six cases, which altogether resembled eceding in their origin and symptoms, but were treated throughout with doses of opium; of these four recovered, and two ended fatally. In one e cases, during a violent fit of laughter, there was a sudden aggravation of mptoms, with nausea, vomiting, hiccough, etc.; after death, an abscess ound between the cæcum and the right abdominal wall, communicating with an ulcer which had perforated the vermiform appendix. In the other fa case, an enema had been given before the patient was admitted into the hospit The necropsy revealed general peritonitis, and a perforation of the appendix large as a pea.

In a third class are placed eight cases, in which perforation was followed local peritonitis of a less severe character; the patients all recovered. In of these cases the author found on the death of the patient, three and a half ye afterwards, that the local peritonitis could be traced to the vermiform append

Finally, in a fourth series are related five cases, in which convalescence protracted, either in consequence of increased peristaltic action of the bow produced by enemata or purgatives, or because the patient sat up too soon.

In order to establish his position, that the greatest part of the affections wh have been named perityphlitis, phlegmon, or abscess of the iliac fossa, are vari degrees of the above-described disease, the author proposes to call it "perito appendicularis," a name which denotes both the nature and the source of disease. It may be divided into three forms. 1. In the adhesive form, ulceration of the appendix vermiformis penetrates so deeply that the inves peritoneum is involved and perforated. 2. Local peritonitis appendiculari characterized by local peritonitis and primary intraperitoneal abscess. 3. U the title universal peritonitis appendicularis are included the cases in which gen peritonitis is the result. In their clinical aspect these forms of the disease differ considerably from one another, and the author therefore gives a sketc the symptoms, diagnosis, prognosis, and treatment of each of them.

1. *Peritonitis Appendicularis Universalis.*—The patients have often earlier attacks, which may be regarded as stages of the same disease which not been further developed; in a few cases, there is indisposition for a few before the perforation; but in most this takes place suddenly. Dr. With collected fourteen cases of this form, of which twelve ended fatally and recovered. In six of the cases, the illness began with local peritonitis w afterwards became general; the duration of the local stage varied from fou fourteen days, that of the universal stage from two to six days. In all the ca the pain was greatly increased when the peritonitis became universal; there vomiting in all the cases, except one in which the perforation occurred du typhoid fever; it was usually accompanied with eructation or hiccough. In the cases, the abdomen becomes very tender and distended, when universal p tonitis sets in; sometimes there is observed painful or difficult micturitio complete retention of urine. There is considerable fever. The temperatu most frequently a little over 102 deg. Fahr., but may rise to nearly 106 The pulse varies from 90 to 140, and towards the end becomes rapid and s There is much thirst, and the tongue is inclined to be dry. The patient's ge condition is much affected; general prostration may occur very rapidly. C sciousness may be retained nearly until death; in other cases there is deliri accompanied, however, with a feeling of being in health. The disease may confounded with various forms of colic (lead-colic, colic from gall-stones, et with ileus, with puerperal peritonitis, etc.; but it can most frequently be tinguished with certainty from these diseases. The diagnosis between perito appendicularis and the other forms of peritonitis from perforation is very diffic but in all such cases the first indication of treatment is to immobilize the inte canal by means of opium.

2. *Peritonitis Appendicularis Localis.*—This condition was observed in cases in which the peritonitis afterwards became general; and in sixteen wh recovered. The symptoms are: considerable pain, coming on suddenly, in abdomen, low down and to the right; vomitings coloured with bile; much

with some distension and resistance in the right iliac fossa, where, when
derness allows an examination to be made, there is found more or less
g; with a tendency to constipation. In many cases, the patients have at
er date had similar symptoms of short duration in the abdomen, with pain,
g, and disposition to diarrhœa or constipation; some have also suffered
licky pains and tendency to diarrhœa just before the attack. The pain
peritonitis appendicularis may vary much in intensity; in some it prevents
lthough the patients can lie quiet; others bend and twist themselves and
eir legs up; others cannot move from the position on the back which they
sumed; the right leg especially is often drawn up. The pain is continu-
d is increased by pressure, coughing, and deep inspiration. Vomiting
n by far the greater number of cases, but, with the pain, is most frequently
bdued by the use of opium; the condition of the abdomen in the milder
natural, except in the right iliac fossa. In the more severe cases, the
abdomen is somewhat distended, but the tenderness and distension are
greatest in the right iliac fossa. The swelling or fulness may vary in form
e, and may yield a dull or hollow tympanitic percussion-sound. There is
ly fever; the temperature varies from 100.4 to 104 deg. Fahr.; the pulse
4 to 100. During the stay in hospital, the spontaneous pain and the
g disappeared within the first few days under the use of opium; the ten-
and distension in the right iliac fossa lasted two weeks, and the duration
constipation varied from four to twenty days. The diagnosis is most often
but, when there is severe pain in the upper part of the right side of the
en, the case may be mistaken for one of gall-stone colic; a consideration
whole symptoms, however, will soon correct the diagnosis. The disease
frequent in men; when it occurs in women, exploration will aid in dis-
hing it from parametritis and other affections proceeding from the genital
. Simple typhlitis is most frequently stercoral, and is developed gradually,
atulence, constipation, and the formation of a painless and frequently nodu-
welling in the cœcal region. Dr. With regards the existence of a primary
phlitis as very doubtful; the group of symptoms generally attributed to
sease belong in reality to local peritonitis appendicularis.

eritonitis Appendicularis Adhæsiva.—This affection is difficult to recog-
n account of its various and uncertain symptoms. In five of the thirty
recorded by Dr. With, the patients had at earlier periods suffered from
oms which, viewed in the light of the latter course of the disease, may be
ed to have had their origin in ulceration of the vermiform appendix with
encing adhesive peritonitis. These symptoms consist of slight abdominal
asting about twelve hours, sometimes accompanied with pain in the cœcal
, nausea, and a single attack of vomiting. There may be alternate diar-
and constipation, with colicky pains, flatulence, and a painful feeling of dis-
n in the abdomen; the symptoms may sometimes be so severe as to oblige
tient to remain in bed for two days. In some cases, on single days, even
hin three weeks before the perforation has taken place, the patients have
l. have had nausea, etc. Most frequently, the pain in this form of perito-
appendicularis is more severe than in ordinary intestinal catarrh; and by
dering the *ensemble* of the various symptoms a probable diagnosis may often
rived at.

e author warns against giving purgatives in all forms of the disease; even
there has been constipation for a long time, he gives opium to subdue the
taltic action. In the milder cases he gives from 5 to 8 drops of vinum the-
m, in the more severe cases 10 drops, three times daily; and besides this,
rding to the severity of the case, 15 drops in the evening or an injection of

15 milligrammes (3-5th grain) of morphia. A warm cloth is laid on the abd-men, as this seems to favour adhesion more than ice-bladders. The patients a put on low diet, and are only allowed fluids; a little milk with ice, and aft wards tea and water-gruel. Rest, and the avoidance of all unnecessary speaki are enjoined; as few visits as possible are made, and the patient is carefully e amined without making strong pressure on the abdomen. In the milder ca the pain disappears in the course of a few days, the vomiting ceases, and th tenderness and distension disappear in five or six days. After about ten days th opium is discontinued, and the bowels are generally opened spontaneously a fe days later.

When the local peritonitis has been more severe, the tenderness, fulness, a swelling continue some time after the pain has ceased. Opium is then giv until all the local symptoms have disappeared—as a rule, about fourteen da In general, the bowels will be open a few days after the opium has been dis tinued; if not, an enema is used, especially if there be any distress. The au has allowed patients to remain with their bowels unopened for twenty-four da

When a spontaneous evacuation of the bowels takes place at a time when th is reason to fear that sufficient adhesions have not yet been formed, the do opium is increased to ten drops of vinum thebaicum three times daily. Wh spontaneous evacuation has taken place, and is not repeated within a few d an enema is used, and afterwards small doses of castor oil. The stools are ge rally scanty and hard at first, but sometimes abundant and natural. The gen health does not suffer at all from the long constipation, but recovery proce quickly, steadily, and without disturbance. The patients become free from p feel themselves better daily, and have appetite, long before the bowels are ope After the bowels have been opened twice, the patients are allowed to have and two days later fricassee; and in a few days they are discharged c Leeches may be useful to subdue the tenderness, both at the beginning of illness and afterwards; when the distension continues rather long, blisters or moxa may be used.

In general peritonitis, also, opium is the chief remedy, and is given in dose from 10 to 20 drops of vinum thebaicum every half hour or hour, with repe injections of morphia; other remedies are of subordinate importance. Adhe peritonitis appendicularis may be treated by rest, warm applications, low d and doses of from 5 to 13 drops of vinum thebaicum three times a day.—*Lo Med. Record*, June 15, 1880.

Rupture of Hydatid Cysts of the Liver.

In a paper read at the Académie de Médecine (*Gaz. Heb.*, May 28), FEREOL observed that this occurrence is by no means so necessarily fatal a was not long since supposed to be. The present state of our knowledge se to justify the following conclusions: 1. Preliminary suppuration gives rise, the case of rupture, to a rapidly fatal peritonitis, except, perhaps, when peritoneum has become partitioned by adhesions which limit the inflammati 2. The penetration of a limpid and fresh liquid into the peritoneum, which some cases seems inoffensive, in others has been followed by rapidly fatal a dents, without our being able to state with precision the reasons of these dif ences. 3. The presence of living hydatids in the peritoneum is less danger than that of dead hydatids; in the former a spontaneous cure is possible. 4. cases in which the accidents that follow the rupture are not severe, or becu moderated, and yet ascites is produced, we should interfere when this ascites not a tendency to become absorbed. Simple puncture may suffice to produc cure, but when this fails we should as soon as possible evacuate the foreign bod ined in the peritoneum. This may be done by washing out the peritoneum a day by means of a large trocar and canula with a wide lateral opening 'auchet's siphon-tube. Dr. Féréol believes that the same practice may be ed in some cases of limited peritonitis.—*Med. Times and Gazette*, June 880.

Surgery.

Gunshot Wound of the Base of the Brain, followed by Recovery.

DIEZ reports a remarkable case (*El Siglo Medico*, No. 1376) of recovery a gunshot wound, presumably of the base of the brain. The patient was nine years, and was accidentally wounded by a revolver bullet, nine millis (0.35 inch) in diameter. The projectile was discharged at the distance w feet only, and passed through the right temporal fossa at a point correing to the centre of the zygomatic arch, between the external angle of the and the tragus of the ear, lodging at a corresponding point, but six millis higher, on the left side of the head. Among the symptoms noticed were l loss of consciousness, recovered, however, within an hour, considerable xis, exophthalmos, with complete loss of vision in the right and photoa in the left eye. Slight cephalalgia, confined to the anterior portion of ead, was present; and a dull buzzing sound, heard subjectively, followed ast movement. Hemiplegia was well marked on the right side of the The ball was extracted, and almost immediately the photophobia in the e disappeared. The treatment consisted in water-dressing and rest; and ry was rapid and complete. Suppuration commenced sixty hours after jury; the exophthalmos disappeared on the seventh, and the hemiplegia third day. Recovery was complete on the twenty-fourth, sight having perfectly restored, and no apparent ill effects remaining. The author asks could have been the actual lesion in this case, and considers that the antebes and optic nerve can hardly have escaped direct injury. [It seems easonable to suppose that the ball did not describe a straight course within anium, although the wound of exit was immediately opposite that of en-. Such cases are not rare in military surgery.]—*London Med. Record*, 15, 1880.

Rupture of the Middle Meningeal Artery.

he numbers of the *Revue Mensuelle* for March and April is a memoir by RARD MARCHANT, of Paris, on ruptures of the middle meningeal artery, ally in association with simple fractures of the lateral portions of the m. One instance of this lesion was observed by the author in 1875, and a l three years later. He has since paid much attention to this subject, and llected, partly from the *bulletins* of the Anatomical Society of Paris, partly unpublished records of hospital colleagues, thirty cases of simple fracture e skull complicated with rupture of the middle meningeal artery. In his oir, M. Marchant discusses the symptoms and treatment of this form of injury, gives also the results of some anatomical and experimental investigations. igns through which the surgeon is enabled to diagnose the complication are o kinds, local and general. The previous history of a suspected case of this is always of some importance, particularly if there be any evidence of a t injury to the affected region of the skull. Chief among the local signs are sed œdema of the temporo-parietal region, pain very intense at one point on pressure, and ecchymosis, appearing some hours after the accident, sometimes in the mastoid region, sometimes in the inferior facial region near the zygoma Occasionally there is dilatation of the pupil on the same side as the effusion. Of the general symptoms, marked stertor is the most constant. The patient is usual comatose, and presents the phenomena of cerebral irritation and compressio The disturbances are, as a rule, diffused, and indications of muscular contracture, relaxation, and resolution appear in different cases in a variable order.

It is only when they are presented in association that these symptoms are of value in establishing the diagnosis of ruptured meningeal artery in cases of injury, without external wound, to the side of the head. Ecchymosis over the zygo and at the lower portion of the temple, is a symptom also of fracture in th mastoid region; stertor, when an isolated symptom presents no special indicatio since it may be observed in any case of cerebral compression.

According to Duret, who has carefully investigated the cerebral phenome produced through increase of pressure within the cavity of the cranium, and may be made out on study of the thirty cases collected by M. Marchant, certai other symptoms have been frequently met with in the above complicated injur Ocular and circulatory disturbances, derangements of digestion, trismus, disorde in the nervous and urinary systems have often been noted; but an attempt make a methodical grouping of these disorders, as symptomatic of this or th lesion, will be found impossible. In future a surgical observer, in dealing with fracture of the cranium and suspecting rupture of the middle meningeal arter ought carefully to note the occurrence of vomiting and of motor and sensory di turbances; he should carefully study the characters of the pulse and of respi tion, and make out the condition of the pupils and the degree of sensibility of th cornea. The last is a valuable index of the degree of cerebral compression: t more the intracranial pressure is increased, the less does the cornea react wh touched.

At the request of M. Marchant, an examination of twenty-five skulls was ma by M. Feré, in order to determine the relations of the cranial walls to the branch of the middle meningeal artery. This vessel is usually described as terminati in two branches, an anterior and a posterior; but, as the anterior is almost alwa subdivided into two trunks of almost equal importance before it reaches the sup rior limit of the squamous portion of the temporal bone, it follows that in ea lateral portion of the cranium, and in the regions most accessible to surgical accidental wounds, the middle meningeal artery presents three large branch Of these, the anterior branch alone is regular in its relations to the cranial wal Below, it is situated at a distance of between 23 and 30 millimetres from the e ternal orbitar process of the frontal bone, and at its termination about 16 mill metres behind the point where the sagittal strikes the coronal suture. It is place in front of the fissure of Rolando, from 20 to 25 millimetres below and about millimetres above. The posterior branch of the anterior division of the artery situated behind the fissure of Rolando, and also behind the ascending pariet fissure. The hindmost branch ascends beyond the squamous portion of the te poral bone, at a point about 83 millimetres behind the external orbitar process the frontal bone; it then approaches the lambdoid suture, with which it possib runs parallel, its direction being cut by a line carried directly upwards from th mastoid process.

M. Marchant recognizes the fact that, in a case of intracranial hemorrhage, th effused blood may be derived from some other source than the middle meninge artery. The bleeding may come from the proper vessels of the diploë, from the vessels running between the bone and the dura mater, from the sinus of the dura mater, or from some large vascular trunk at the base of the cranium, as the al carotid or the internal jugular, or, again, from some of the numerous ls that surround the encephalon, and penetrate into its interior. But it has found that intracranial effusion of blood from any other source than the le meningeal artery is very rare. In twenty-six of thirty-one collected cases, leeding had been from this vessel. In the rarer forms of injury, the clinical omena differ from those described by the author as characteristic of rupture e meningeal artery.

e most frequent cause of rupture of the middle meningeal artery is direct from a splinter of cranial bone. An injury of sufficient force applied to de of the skull produces a fracture of both tables of the cranial bone. If dy effecting the injury be angular and strike the cranium with a small sur- it causes a form of direct comminuted fracture, in which are presented a n number of fragments, usually triangular in form, depressed each at its it, and continuous at the base with the cranial wall. The depression is or less marked, and may vary in depth from a few millimetres to 3 or 4 netres. In this form of injury, the dura mater, which is less adherent in teral regions than in other portions of the cranium, will probably be stripped from the bone; and if the injury have involved at any part the track of a branch of the middle meningeal artery, this vessel will probably be wounded e sharp extremity of one of the depressed fragments of bone. This view as most likely cause of rupture of the middle meningeal artery is supported e fact that, in the majority of reported cases of this injury, there is a history ll on some projecting part or of a blow from some pointed or sharp body. racture associated with rupture of the meningeal artery is usually a starred nd so indicates the frequency of direct injury in such cases. The effused collects between the bone and the detached dura mater, and very often, in quence of extensive separation of this membrane, forms a large clot. A l but much less frequent cause of wound of the middle meningeal artery, is ible rupture through injury of the osseous ring or canal which frequently es the anterior division of the vessel before its ramification.

the first variety of the injury, comminuted fracture of the lateral wall of kull through direct violence and wounding of one of the branches of the e meningeal artery, there will be speedy and grave symptoms of cerebral ression, due to effusion of blood between the bone and the dura mater, and a zone corresponding to the extent of the separation of the membrane. zone, as has been made out both by experimental and by pathological ch, extends from the posterior margin of the lesser wing of the sphenoid to a line about one inch from the internal occipital protuberance, and in this ion is about five inches in length. From above downwards it measures r less, commencing at a short distance below the sagittal suture, and being led below by a horizontal line carried from the sharp posterior margin of esser wing of the sphenoid, just over the superior margin of the petrous n of the temporal bone to a point above the horizontal portion of the lat- inus. In this form of injury temporo-parietal ecchymosis and infiltration of may be produced in two ways. It is most frequently the direct result of njury, the contusion of the skull producing at the same time ecchymosis, ation of blood, and fracture. The effusion in such cases is usually limited tent, and has no tendency to increase. In some instances, though very , the ecchymosis is due to the filtration of blood between the fragments of , and through the lacerated epicranial aponeurosis; in this variety, there is dency to increase in the amount of effused blood.

the second variety of injury to the middle meningeal artery, that in which ep canal or an osseous ring, occupied by the anterior branch of the vessel, is divided through indirect violence and the extension of a fracture from the vau to the base of the skull, effusion of blood, in consequence of concomitant laceration of the dura mater, takes place within this membrane, and varies much i volume in different cases. The symptoms of cerebral compression may be wa ing in an instance of this kind, and it is sometimes impossible to make a diagnosis. The prognosis is usually less unfavourable than that of the first form injury. Here either the main trunk or the anterior branch of the middle meningeal artery is the starting point of the hemorrhage.

During life the anatomical diagnosis, that is to say, the determining whi branch of the meningeal artery is the source of the bleeding, rests only on prob bilities. Still, observations as to the seat of the injury, the most painful poin and the region involved in the ecchymosis, associated with knowledge of the rel tions of the branches of the middle meningeal artery to the cranial wall, might some cases enable the surgeon to refer the source of the effusion to the anteri or posterior branch of the vessel. The diagnosis would be much facilitated the existence of a scalp-wound.

The anatomical diagnosis is often attended with much difficulty, even af death. The arterial rupture may vary in extent from a well-marked division one or several branches to a scarcely appreciable puncture. In some cases th is hemorrhage *en nappe*, which apparently has its origin in the vessels passi from the dura mater to the bone.

In some cases of compound fracture of the cranium, especially in the infant, consequence of the close adhesion of the dura mater to the bone, of the tenden of the blood to escape externally, and to form a superficial and extracran hemorrhage, and, again, of the superficial position and clean section of the arte surgical intervention—trephining and deligation, may present some chance success. With the adult and aged, trephining is thought to be useless in majority of cases. The intracranial accumulation of blood is as a rule wid diffused, and is not accessible over the whole of its surface. Moreover, it is possible to remove so large and firm a clot as is usually formed without caus some meningo-encephalic irritation, and giving rise to septicæmic complicatio This clot forms a very good hæmostatic, and frequently, if the surgeon attem to remove it by a curette or by washing it away, he will find it necessary to d with fresh bleeding, the starting point of which there may be some difficulty discovering. If the origin of the hemorrhage can be made out, it is often fou to be in an artery deeply seated within the cranium, and covered by a fold dura mater. Another contra-indication is the fact that compound fracture of side of the skull, with rupture of the meningeal artery, is almost always associat with cerebral contusion on the opposite side of the head—the so-called lesion *contrecoup.—London Med. Record*, June 15, 1880.

New Mode of Treatment of Gonorrhœal Ophthalmia.

M. Dor, of Berne, remarks (*Lyon Médical*, March 7, 1880) that sin Graham Brown published, in October, 1877, his *Researches on Diphtheri* and came to the conclusion that benzoate of soda is a very powerful disinfecta he has not hesitated to employ that salt in all cases of purulent ophthalmia new-born children that have come under his care, as well as in a case of dip theritic conjunctivitis. The benzoate of soda was, however, only employed a disinfectant, tannin being also used as a curative agent. The following case gonorrhœal ophthalmia was thus treated. A man, aged 20, suffering from gon rhœa, was, when first seen by the author, suffering from purulent ophthalmia both eyes, of four days' duration. M. Dor prescribed iced-water compresses, an ation of benzoate of soda (1 in 20), and solutions of tannin (1 in 10, and 1 0) as eye lotions, to be used every ten minutes. The next day the eyes less painful, and in five weeks were well, the cornea being intact.—*London Record*, June 15, 1880.

Paracentesis of the Anterior Chamber of the Eye.

. **Mengin** (*Recueil d'Ophthalmologie*, May, 1880) argues strongly for the treatment in all chronic abscesses and ulcers of the cornea. He considers t gives better results than any other method, and is moreover an excellent uard against perforation. In phlyctenular, vesicular, and pustular keratitis, the affection has lasted more than four or five weeks, there should, in his on, be no hesitation about performing paracentesis. Should one operation e sufficient, it may be repeated at frequent intervals. In ulcerative kera- where pain is felt along the course of the branches of the fifth pair, he lers the operation especially indicated, as also in abscesses with hypopion. h cases it is sufficient to puncture the centre of the affected part, without g a large section. Such a paracentesis is more especially called for in ses of traumatic origin, as soon as any haziness of the aqueous humor or reatening of hypopion is noticed. As regards the objection that paracen- may cause prolapse of the iris into the wound, the author considers it to no force, more especially as eserine can always be used, if required, before eration.—*London Med. Record*, June 15, 1880.

ortive Treatment of Furunculous Inflammation of the External Auditory Meatus.

. **Weber-Liel** recommends (*Deutsche Medicinische Wochenschrift*, April 380) in boils of the external meatus, subcutaneous injections of a 5 per cent. on of carbolic acid. Two to four drops of this are to be injected by one or punctures, the point of the injecting syringe being inserted into the swollen o a depth of one or two millimetres. When these injections are performed early stages, before formation of pus has taken place, the further develop- of the local inflammation is, according to the author, prevented. In quite rly stage, a single injection often suffices, followed by ear-baths of rectified containing a minute quantity of corrosive sublimate. When the boil is advanced, several injections, either at one sitting or at different times, may quired to produce local anæsthesia of the parts. The author cautions against se of an impure solution of carbolic acid, or of a larger quantity than from o four drops at the commencement. If this fail to produce complete anæs- , the injection may be repeated the same evening, with the addition of three of the fluid.—*London Med. Record*, June 15, 1880.

Antiseptic Treatment of Suppuration of the Middle Ear.

rfect disinfection of the whole wounded surface and complete closure from ir, which are the two chief conditions of an effective antiseptic dressing, at first sight to forbid the application of these principles to diseases of the anum, for it is impossible either to close the Eustachian tube hermetically, disinfect all the irregularities of the tympanum and mastoid thoroughly. ery, however, **Bezold** says, has these same conditions to deal with in the hbourhood of the mouth and nose, around the genitals and the anus, and yet rience shows that in these parts an incomplete antiseptic dressing is of value. isinfection by syringing with potash permanganate and carbolic acid has been se for a long time, and Von Troeltsch has recommended that the meatus be closed with charpie saturated with carbolic or salicylic acid, in order to preve the deposit of new spores after the inflamed surface has been thoroughly cleanse

In selecting an antiseptic for the ear it is necessary that it should not be i tating to the mucous membrane of the tympanum, and also that it should n form deposits either by itself or by chemical union with the natural secretions, such deposits often act as mechanical irritants.

Carbolic acid, although useful in one-half to one per cent. solution for cleansi in cases of caries or necrosis, is not well borne, according to Bezold, by the ty panic mucous membrane in uncomplicated purulent otitis media ; for, from its u in such cases, the mucosa becomes more swollen and the secretion is increased.

In chronic suppuration of the tympanum, Bezold found the use of salicyli acid, especially in alcoholic solution, useful; but the same is not well borne i acute cases. Thymol acid, he says, is also non-irritating, but his experience it was slight, and he does not speak of results.

After experimenting with all of these, however, with more or less succe Bezold has given them up since learning the virtues of boracic acid, which considers equal to any of the other substances as an antiseptic, and it has t advantage over them of producing no reaction of the tympanic mucous membra Boracic acid has been long in use in Sweden as a secret remedy, under the na of aseptin, but was first brought into notice by Lister, in 1875, since which ti it has been very extensively used in the clinic of Professor Nussbaum, and fou to give equally good results as carbolic acid.

After first trying a saturated solution of the acid, and getting no better eff than from similar solutions of the other antiseptics, Bezold tried filling the me tus with finely pulverized boracic acid; and, as the result, he asserts that t method of treatment is so much more certain, and so much quicker than the oth methods that he now uses it in every case of suppuration, either of the meatus tympanum, and also after lesser operations, such as the removal of polyp granulations, cauterizations, and paracentesis. With caries of the bone it is as effectual as in the uncomplicated cases, which would be expected. He d not consider that it supplants but rather assists other methods of treatment, li the antiseptic dressing in surgery; cauterization of granulations, removal polypi, etc., are as necessary as ever.

The meatus and tympanum are first carefully cleansed with a four per ce solution of the acid, then dried thoroughly, and finely pulverized boracic a blown in over the suppurating surface; the meatus is then closed with salicyli carbolic, or boracic cotton, which should be renewed as often as it becomes mo from the discharge.

Statistics are given to show the favourable action of this treatment upon twent nine cases of otitis media purulenta acuta; the average duration of the otorrh in these was only thirteen days. Of one hundred and sixteen cases of oti media purulenta chronica, the average duration of treatment to the cessation all discharge was nineteen days.

The pulverized acid has the advantage of producing no reaction on the muco membrane, of withdrawing the water from the membrane, which keeps a concentrated solution in contact with the inflamed surface, and of not forming coagulations with the secretions. In cases of otorrhœa complicated by phthisis of th lungs Bezold found that the acid had no effect upon the discharge.

Since the appearance of Bezold's paper boracic acid is highly spoken of b BÜCKNER[1] for the conditions described in the original paper and also as a loc application for eczema. The experience of the reviewer, who has used Bezold treatment very extensively for the last year, is also extremely favourable.

Excision of the Thyroid.

ILLAUX lately brought before the Académie de Médecine a case in which
of the thyroid had been successfully performed for goitre, believed to be
"exophthalmic" form. The patient was a woman twenty-nine years of
d the thyroid was enlarged to the size of the fœtal head at the full time.
nded from the thyroid cartilage to below the notch of the sternum, and on
side as far as the anterior border of the trapezius. She suffered from
palpitation of the heart, and the pulse was never less frequent than 130
per minute. There was very little prominence of the eyeballs, but she
ned of dysphagia, and there were amenorrhœa and marked vaso-motor
nces. In the operation Lister's antiseptic method was strictly observed.
que incision was made from above downwards, parallel to the anterior
of the sterno-mastoid, and then a horizontal incision perpendicular to the
On reaching the thyroid, M. Tillaux endeavoured to separate the capsule,
nd great difficulties in doing so, each movement of the grooved director
a jet of blood. The capsule adhered so firmly to the thyroid that it was
ry to apply more than fifty hæmostatic forceps to restrain the hemorrhage.
ishing the attempt to attack the right lobe of the tumour, he made a
oblique incision parallel to the first, on the left side, and obtained thus a
hich he raised over the chin. There were no adhesions on the side, and
roid body was enucleated without difficulty. The bleeding points were
. It was noticed that when the trachea was exposed, after the removal
mass, there was great difficulty of breathing, but as soon as the flap was
d, and the trachea covered, the dyspnœa at once ceased. A drainage-tube
ced on the lower extremity of the wound. For four days all went well.
fifth there was free hemorrhage from the left crico-thyroid artery, from
he suture had escaped, but it was arrested without difficulty. From the
the operation the woman had not a single attack of suppuration; the
henomena also disappeared, and the woman made a good recovery. M.
UD doubted whether the case was really one of Graves's disease, believing
e absence of exophthalmos must leave the diagnosis in doubt. The fre-
of the pulse is, however, in favour of the view. Even as a surgical suc-
e case is of considerable interest.—*Lancet*, June 26, 1880.

Introduction of Tubes into the Larynx through the Mouth.

he first number of the present year of the *Monatschrift für Ohrenheil-*
Dr. MACEWEN records two cases of successful dilatation of the larynx
ans of tubes introduced by the aid of the mirror through the mouth. Both
cases were acute œdema of the glottis supervening upon stenosis. In a
instance, Dr. Macewen introduced the tube into the larynx before the
al of a carcinoma of the pharynx, to prevent blood from escaping into the

---

[1] Practitioner, April, 1880.

larynx during the operation, and to facilitate the administration of the anæsthetic. [Dilatation of the glottis by means of tubes has been successfully practised b Schrötter, and is strongly advocated by him in preference to tracheotomy for th relief of acute œdema of the glottis.]—*Lond. Med. Record*, June 15, 1880.

Cysts of the Vocal Bands.

In the first number for this year of the *Breslauer Aerztliche Zeitschrift* Sommerbrodt published four cases in which cystic tumours were found on th free edge of the vocal bands, and five other cases in which most probably suc cysts existed. In three of these cases the cysts were opened. They appeare as nodular or spindle-shaped thickenings of the edge of the vocal bands, of th same white tendinous colour as that of the normal band. The depression, th can be easily produced on them by touching them with a probe, serves to di tinguish them from fibromata. Dr. HEINZE, to supplement these cases, recor the following (*Archives of Laryngology*, vol. i. No. 1, 1880). The patie was 40 years of age; he had suffered for many years from repeated attacks laryngeal catarrh. Latterly they had sometimes passed off, either suddenly in a remarkably short time, so that the hoarse voice at once became deep a almost quite clear. A spindle-shaped tumour was discovered on the free edge the left vocal band, about 1 centimetre long and ½ centimetre broad. It was a grayish-white colour, slightly bluish at the middle, smooth, and shining. slight depression could be produced by pressing on the middle of the swelli with a probe. On a subsequent visit the patient's voice was almost clear, a the swelling was reduced to one-half its former size. There was a distinct fa ing in of the edge looking towards the opposite vocal band. The cyst had e dently spontaneously ruptured; the rest of the growth, which felt quite fi under the probe, disappeared after repeated incisions, and the patient was missed with a normal vocal band and clear voice. In this case the walls of cyst were firmer than in those of Sommerbrodt, where the cysts disappear immediately after incision and emptying of the contents. Dr. Heinze thi that the repeated loss and sudden recovery of the voice were due to the altern filling and rupture of the cyst, and he would regard this symptom as one of t characteristic signs of the affection. Cysts in this situation do not appear to very rare. The cases operated on amount at least to 17, those observed to ma more.—*Lond. Med. Record*, June 15, 1880.

—

Abdominal Surgery.

Prof. VON NUSSBAUM, is well known as a bold and fearless operator. He h already introduced many new operations—among others, nerve stretching and re totomy—which our forefathers would hear of with something akin to incredulit Now we find him attempting to remove the pylorus for what was diagnosed as ca cer. On cutting down on it, the pylorus, however, proved to be healthy, and th tumour or induration was found to affect the liver. Nothing daunted by the mi take, Nussbaum, who was conducting his operation under the strictest antisep precautions, decided to incise the organ and put in a drainage-tube, in the ho that irritative softening might ensue, and so lead to its absorption. It was in a address before the Munich District Medical Society that he referred to this su ject and to peritoneal surgery in general. In a manner all his own the celebrat operator contrasted the results of peritoneal wounds under the present methods treatment with those which were formerly obtained under the older method

He says (*Aertzliches Intelligenz-Blatt*, January, 1880), "When nowadays w read that the peritoneum may, fearlessly and with impunity, be punctured, in-

, lacerated, bruised, or burnt, provided we keep off all infectious germs, one
t be inclined to think that our predecessors had lived under a gigantic error
garding abdominal injuries as almost fatally dangerous, while in reality they
proved themselves to be quite unattended with danger, seeing that we now
ve from the belly tumours weighing fifty to sixty pounds, the patients
ely feeling ill the while, and not experiencing either elevation of temperature
en a rise in the pulse-rate." Fortunately the facts are beyond dispute, and
he older surgeons were nowise in error, for peritoneal wounds were danger-
and in similar surroundings are so to-day. "The difference between the
mes and the present simply consists in this: that we have learnt the sources
danger. An enemy whose strength and position are known is easily over-
."

nong the principal dangers attending this kind of injury must be reckoned,
ys, the great susceptibility to the influence of cold which the peritoneum is
n to possess. "This enormous, constantly moist surface, when exposed,
to such a rapid cooling of the blood, that immediately reflex paralytic condi-
of the heart, and even death, are threatened." The second source of dan-
the almost unlimited power of absorption which the peritoneum possesses;
hus, any exudation into it which may have undergone unhealthy metamor-
s is liable to bring about rapid and severe septic conditions. Thirdly, peri-
action, by means of which any exudation that gets into the peritoneal
, an enormous surface, is stirred up and smeared over the whole of its con-
Fourthly, movements of respiration, the rise and fall of the diaphragm
mall intestine aiding the absorption. Fifthly, peritoneal wounds are dan-
s because of the little spaces which everywhere exist, into which secretions
find their way and lie hidden and decompose. And, finally, there is the dan-
f infection through the ill-smelling intestinal gases, which especially favour
; and, he continues, even if the bowel itself be not injured, gases find their
n or out. Thus it is that the pus of all abscesses forming in the neighbour-
of the intestines smell of fecal gases; and not only gases, but after concus-
and its consequent paralysis, owing to the phenomena which attend it, an
nosis of fluids may actually take place. On the whole, therefore, we see
there were good grounds for the dread which has hitherto always been felt
ritoneal injuries, whether accidental or applied by the surgeons for surgical
oses. Since, however, the causes of this great danger have come to be under-
, and the means by which they may be overcome have been learnt, the indi-
ns for operation and prognosis afterwards have been greatly modified.

ofessor Nussbaum then considers enterotomy and gastrotomy, and the cases
hich these operations may be practised. In speaking of cases of internal
gulation, he said that "thousands now lie in their graves who have died from
distressing disease, while surgeons stood by as mere lookers-on, unable to
their patients." For although opium could relieve pain for awhile, it gene-
failed to cure the obstruction. And as regards laparotomy, formerly the
ality was 70 per cent., that of Littré's operation 47 per cent., that of Amus-
0 per cent., while those who did recover were, on account of their infirmity,
very miserable and quite unfit to associate in society.

ow in consequence of greater skill, and of the experience of past operations,
esults are much more favourable. He thinks that a small opening, just large
gh to let out feces, is all that is required at first; for often, after tension of
distended intestines has been relieved, the twist will right itself; or if the
ruction be due to invagination, the gut will slough and come away. The
ning is then allowed to close; but, if a cure cannot be effected, the opening
ld be enlarged, and a permanent artificial anus established.

As regards gastrotomy, he speaks most hopefully. Quoting some Vienna tistics of cancer, he mentioned that of 903 cases affecting the stomach, 542 curred at the pylorus, and that of these about 60 per cent. offered favour chances for operative interference. He pointed out that portions of the stom and pieces of gut had been successfully removed in animals in many instance and he believed that we were not only justified, but called upon, to operate wh circumstances seemed to call for it.

In support of this doctrine he relates the following case:—

A man, aged fifty-six, was sent to him with what was believed to be a cancer tumour of the pylorus, and which could be felt as a swelling of the size of an over the pyloric region. It was accompanied by intense pain. An indura cicatrix on the abdominal wall led to the discovery that he had been acciden injured with a pistol, and it was then thought that the wad might have lodged. After watching the case for a while, it was decided to cut down upon and explore, being ready for any eventuality. The lesion proved to be an "flammatory exudative process" in the liver. It was not sufficiently circumscrib to be removed; and furthermore, it seemed not to be a deposit in, but rathe part of, the liver. Professor Nussbaum, under these circumstances, put drainage-tube, in the hope that absorption of the indurating material might brought about. The pain almost ceased, and the induration lessened. The tient left the hospital very much better for his operation, but not quite cured. wrote to his doctor after some time, asking to undergo a second operation, in hope that he would thus get quite rid of his trouble.

Nussbaum thinks that with antiseptic precautions we shall be able to ex our peritoneal operations to an almost unlimited extent. He believes we excise the pylorus, when cancerous, with confidence of success. If this sh prove to be the case, we have indeed in antiseptics (so-called) a valuable add to surgical science. But we trust that in this, as in other arts, discretion wi regarded as the better part of valor.—*Med. Times and Gaz.*, May 22, 1880.

Death from Division of the Obturator Artery in Herniotomy.

Two cases of death, following the operation for strangulated hernia, and both cases due to a division of an abnormally distributed obturator artery, recorded in the *British Medical Journal*, May 1880, p. 695. In case 1, a man, aged 62, operated upon by Mr. COULING, in the Sussex County Hosp there was free bleeding on dividing Gimbernat's ligament, which appeared to easily controlled. Next day, there being bleeding from the wound, incapable being controlled, the wound was opened up and the bleeding point searched but without success. The patient died on the third day. On examination, tissues in the neighbourhood of the wound were found infiltrated with blood, this extended beneath the peritoneum as high as the umbilicus. The hemorrh was found to proceed from the complete division of the obturator artery, wh arose from the external iliac in common with the epigastric, and crossed over femoral sheath and along the inner margin of the crural ring. In case 2, a man, aged 64, operated on by Mr. JOWERS, a similar position of the obtura artery was found after death, but here the artery was only partially divided, no external hemorrhage took place, but extensive subperitoneal effusion.—*Lo don Med. Record*, June 15, 1880.

Treatment of Prolapsus of the Rectum in Children.

Dr. BASEVI (*Giornale Internazionale delle Scienze Mediche*, Fasc. 9) recom mends the following treatment in chronic cases of this affection: He first ligh

erizes the protruded portion with nitrate of silver, and subsequently reduces
lministering afterwards, with the view of checking any tendency to enteritis,
nema composed of tannic acid, alum, and ice-cold water. Should this treat-
prove insufficient, the child is placed on a bed with the nates upwards, and
lied by two assistants, one of whom fixes the upper part of the body, while
ther holds the knees elevated and somewhat abducted. The prolapsus hav-
een reduced, the nates are brought together, and two strips of diachylon
er, each about two inches wide, passed from one trochanter to the other, in
se proximity as possible to the perineum. To keep them in place, a spica
age is applied round the lower portion of the body, while a piece of gutta-
a is added to protect the plaster from the contact of fecal matter. The
atus may be left in position for a period of two weeks.—*London Med. Rec-*
June 15, 1880.

Incontinence of Urine.

Manual Estrada (*El Medico y Cirujano Centro Americano*, No. 2)
s a case of incontinence of urine in a child, three years of age, with whom
us remedies had been tried and failed. A careful examination of the exter-
gans of generation showed that the labia minora had become united, and
ealed up completely the orifice of the vagina, leaving, however, the meatus
ius free. The labia having been divided with a bistoury, it was then found
he hymen consisted of muscular fibres, extending in a direction from below
rds, and intercrossed. Their action would be to draw the urethra down-
, and, in this way, to exercise traction on the trigone of the bladder, with
esult of causing irritation, and probably incontinence. The treatment,
was perfectly successful, consisted in dividing the parts freely, and fasten-
hem back with sutures to prevent reapposition. The author calls attention
necessity of examining the external organs of children carefully in all cases
ontinence of urine, where the usual remedies have failed.—*London Med.*
rd, June 15, 1880.

Removal of a Neoplasm from the Bladder.

fessor **Marcacci** relates a case (*L'Imparziale*, February, 1880) in which
uminated the interior of the bladder by magnesium light, the rays being pro-
l into the interior of the viscus by a concave mirror. By this means he was
ed to diagnose the existence of a neoplasm, which proved, on examination,
villous in structure. The bladder was laid open anteriorly throughout its
extent by a suprapubic incision, the peritoneum being necessarily divided.
ugh this large opening, the growth was removed in fragments. At the time
iting, nine days after the operation, there had been no untoward symptoms,
he case promised most favourable.—*London Med. Record,* May 15, 1880.

Prognosis and Treatment of Primary Syphilis.

Mauriac, in *La France Médicale*, March 3, 1880, and following num-
considers, at some length, the prognosis and treatment of the primary mani-
tion of syphilis. The chancre is looked upon by Mauriac as the first sign
general constitutional disease of indefinite duration. Unfortunately, we
not yet discovered any rules which permit us to foretell, with any certainty,
the character of primary chancre, what will be the number, nature, pro-
, duration, etc., of the later manifestations.

he primary lesion when extensively ulcerated or phagedenic, may, to a cer-
extent, lead us to expect a grave form of early outbreak of the constitutional

disease ; but it does not give us any exact information as regards the prognosis
the later periods, nor as to whether visceral lesions are likely to occur or not.
With respect to the prevention of general syphilis by excision of the init
lesion, the experiments of Auspitz, Unna, and Kölliker, are referred to ; and
author states that M. Paqvalin, of Abo, Finland, informed him that he had
out infected chancres in eighteen cases, in one in which he had also removed
inguinal glands. The chancres were of one or two weeks' duration. In no c
were general symptoms prevented. M. Paqvalin also had under observation t
men who had had intercourse with the same syphilitic woman. One of the t
men got the skin of the penis chafed during coitus. The excoriated spot
excised at the end of eight days. No syphilis appeared. The other man
an infecting chancre at the end of thirty days. M. Mauriac thinks that, altho
the practice of excision has not yet given proof of being of incontestable value,
should not, therefore, be neglected. However, that this abortive method may
placed beyond criticism, several conditions, rarely found in the same person,
necessary. First, one ought to be sure of the diagnosis. But, asks Mauriac,
this possible during the first few days of the sore, and before adenopathy has
peared ? And if the glandular enlargement were already present, would it
be too late to prevent general syphilis ?—*Lond. Med. Record*, June 15, 1880.

Traumatic Lesions in Syphilis.

Dr. FOLINEA (*Giornale Internaz. delle Scienze Medische*) discusses the v
ous ways in which syphilis may affect wounds, adducing cases in support of
of his propositions. He finds he can class all the influences of syphilis on wou
under one of the following heads, viz.: 1. Syphilitic manifestations on
wounded part. 2. At a distance. 3. Constitutional after a wound. 4. O
pying the site of a wound, itself due to syphilitic contagion.—*London*
Record, June 15, 1880.

Treatment of Syphilitic Ulceration by Pyrogallic Acid.

M. VIDAL made his first experiments with pyrogallic acid (*Bulletin Gén*
de Thérapeutique, February 29, 1880) in psoriasis in June, 1878, and has
employed it with success in the treatment of venereal ulcers. A man was ino
lated with the matter of his soft chancre at two places on the abdomen. Ph
dæna attacked the punctures, as well as the original sore. The sore on the p
became as large as a franc, that of the right side of the abdomen increased to
size of a five-franc piece, and that of the left side of the abdomen to the siz
a two-franc piece. Under repeated cauterization with sulphate of copper
ulcers improved for a time, but again relapsed. At the end of a month,
Vidal made use of an ointment composed of one part of pyrogallic acid to
parts of vaseline. Three applications were made during three successive da
The pain was moderate, and only lasted from eight to ten minutes. The s
then decidedly improved, and after three more applications healing rapidly t
place. Subsequently, M. Vidal used the same ointment for ordinary chanc
and in two cases rapid and complete cure followed the third application. O
the pure acid was applied, but was no more effective, perhaps even less so, t
the ointment. In one case, auto-inoculation on the third day, after a third app
cation of the ointment, gave a negative result.—*London Med. Record*, J
15, 1880.

Simple Chancre and Chancrous Adenitis.

Horteloup (*Annales de Dermatologie et de Syphilographie*, Jan. 1880,) begins his paper with the remark that the soft chancre shows, of all eal diseases, the greatest variation as regards the frequency of its occurrence. , about 1865, there were admitted at the Hôpital du Midi, three simple res to two syphilitic ones. During the siege of Paris, the Commune, and llowing year, there was a considerable increase in the number of simple res; but in 1873, and especially in 1874, a change took place, and simple re became almost an exception. At the end of 1878, however, an increase occurred, which was kept up during 1879. M. Mauriac has dealt with ibject in a memoir, entitled, *De la Rareté Actuelle du Chancre Simple.* lorteloup then proceeds to formulate the two following conclusions with l to chancrous adenitis, and states that he hopes hereafter to fully establish truth by more extended observation. 1. *An adenitis produced by the port of chancrous pus to the gland may present all the characters of a inflammatory adenitis.* In such cases, the aspect of the wound is so le that inoculation alone can remove the uncertainty. The author has ith cases where everything indicated simple adenitis, and yet inoculation positive result, as in the following case. On June 14th, 1879, a man, 22, was admitted to the Hôpital du Midi with two simple chancres of fifteen duration. In the left groin was a red non-fluctuating swelling. Three ater, deep fluctuation could be made out, and an incision was made. The course of the bubo, and the aspect of the chancres suggested a virulent is. The pus of the bubo was inoculated on the patient's flank the day ncision. In forty-eight hours a characteristic pustule appeared at the site puncture, and progressed regularly for eight days, when it was destroyed iterization. It was thus certain that the bubo was a chancrous one. It owever, none of the usual characters of the virulent bubo; the edges of cision did not ulcerate, or become irregular or separate; the floor of the l granulated healthily, and healing was complete by the twenty-fifth day. ng from this and other similar observations, the author thinks that it is imle to be sure of the nature of adenitis in the absence of inoculation. 2. *crous pus conveyed to the glands may there undergo an incubation of several s without manifesting its presence.* The following case, in Horteloup's n, proves beyond doubt that the period of incubation of chancrous adenitis e very long. E. V., aged 26, was admitted on March 12th, 1879, with rating adenitis of the left groin. He had contracted a subpreputial chancre beginning of Feb. 1879, and had been treated as an out-patient at the On admission, the chancre was healing, the bubo was incised, and healed quickly, without showing any virulent character. On April 15th the it went out, having no trace of his chancre and no swelling of the inguinal s. In the middle of July he felt pain in the groin, and returned to consult loup, who could find no swelling of the inguinal glands. No lesion of the or anus could be discovered, and the man, who had examined himself with care, affirmed that he had had nothing since the chancre in the preceding h. In spite of palliative treatment, the patient continued to suffer, and, at nd of August, some puffiness about the glands in both groins could be made On November 19th, the patient was readmitted with two violet-red fluctububoes. Both were incised, a drainage-tube being inserted into the right The day after incision, inoculation was practised with success. Moreover nan accidentally inoculated himself on the forehead. The left bubo became edenic. Here was a man, says M. Horteloup, who suffered from double virulent buboes, the origin of which must be referred to a chancre which had been healed for three months. The author finds it difficult to believe that the patient could have had another chancre which had escaped observation, for the man was very nervous, and had carefully and frequently examined himself. Besides, M. Horteloup had not lost sight of him since the pain came on in July, so that a sore would not have been likely to escape notice.—*London Med. Record*, June 15, 1880.

Sebaceous Cysts in the Sole of the Foot.

Surgeon-Major CAMERON observes (*Indian Med. Gaz.*, May, 1880) that it is generally stated that sebaceous glands are absent from the palm of the hand and sole of the foot. In 1875 a police-constable in good health was sent into the hospital on account of an intractable ulcer at the side of the foot, measuring three quarters of an inch in diameter. Its margins, composed of the tissues of the skin, were raw, red, smooth, and healthy-looking. Its base was covered with a brownish-coloured, inert-looking membrane, which, when unfolded by means of a probe, was found to be comparatively insensitive and to present a smooth, glistening, secreting surface on the side towards the exterior. It was removed by avulsion, and the ulcer, which had hitherto resisted treatment, healed quickly. The portion of the membrane removed had the characters of a cyst of a vein, and consisted only of a portion of the original cyst—the external portion having been lost by ulceration. It was dense and thick, and, having a free outlet, it contained no mass of fatty, pultaceous secretion, but felt and looked greasy. The history was of a small painless swelling on the sole, of its gradual enlargement, its becoming painful and bursting, and finally the formation of the ulcer. In 1877 a strong and healthy man came with a dense resisting cyst, the size of a marble, placed under the skin of the plantar surface of the fifth metatarsal bone, the skin over it being red, painful, and adherent. It was obvious that this was an earlier stage of the affection mentioned above, and this was proved by incision and avulsion of the cyst. It was an ordinary enlarged sebaceous cyst, containing fatty, pultaceous matter.—*Med. Times and Gazette*, June 12, 1880.

Puncture and Incision in Joint-Diseases.

Dr. TIMOTHÉE PIÉCHAUD, in a recently published thesis, shows that the surgical treatment of the joints had to contend with unceasing opposition before it was received into general practice. In the last century, M. J. L. Petit laid down in the clearest way, in the special case of purulent arthritis, the rules which at present form the basis of the new method, viz., to open early, to make large openings communicating one with the other, and to give preference to injections. In M. Boyer's opinion, purulent arthritis, hydrarthrosis, foreign bodies in the joint, and chronic arthritis are more or less amenable to incision or puncture. Before going deeply into his subject, M. Piéchaud recalls to mind the disorders brought on by suppuration in wounds of joints, detachment of the periosteum, destruction of the cartilages, necrosis, hectic, purulent infection, and phlebitis. Arthritis, which is sought for by conservative surgery, has none of these dreaded consequences; but ankylosis in its various forms is always very troublesome. The author insists on the necessity of a thorough acquaintance with the technical details of Lister's dressing before meddling with special surgical treatment. M. Piéchaud does not touch on simple puncture, as it has been practised up to the present for hydrarthrosis: but traumatic effusions of blood, Schede's operation or antiseptic puncture, purulent arthritis, obstinate and chronic hydrarthrosis, foreign bodies in the joints, irreducible luxations, and white swelling, all affections to arthrotomy is applicable, are treated in different articles in M. Piéchaud's . Up to the time of Jarjavay in 1866, no one in France dared to use the or lancet in effusion into a joint, distended by blood after a wound. At resent time, puncture is recognized as harmless in sanguineous effusions. A puncture or two, at the utmost, suffices, and should be made as soon as le; for, after four days, clots may prevent the escape of the fluid, and in ase M. Labbé does not hesitate to use the lancet. The sometimes extremely pains are immediately calmed by the operation. The patient is cured in an a month; whilst, if expectant treatment be relied on, the blood is not bed at the end of six months, or even longer. It is necessary for Schede's d that every effusion of which the tendency is doubtful, and which seems to be of long duration, should be immediately treated by puncture, followed ection of a 3 or even 5 per cent. solution of carbolic acid. Carbolic acid not seem to have any specific action, and may be advantageously replaced dine in certain obstinate cases. Complete evacuation is especially imt; and washing out should be continued until the liquid returns perfectly Puncture clears only recent hydrarthrosis without lesions of the deep . In relapsing, obstinate, or essentially chronic cases, Lister and his disuse large antiseptic incisions. When incision is used in arthritic effusion, sult is rapid cure, complete absence of relapse, and preservation of move- Here, M. Piéchaud follows the precepts of the new school, and inculcates cessity for caution, whilst recording the excellent results obtained in France I. Lucas-Championnière, Panas, Terrier, and Pernsot. His conclusion is uous, but the inference may be drawn from it that arthrotomy should be red to the injection of iodine, when the classic methods have been exhausted . Acute suppurative arthritis, either in its simple form, or connected with yelitis, either purulent pyæmic arthritis, or that consecutive on phlegmonysipelas; and the form consequent on wounds, blennorrhœa, or rheumatism, r arthrotomy in various degrees, and without any hesitation. Otherwise, e will supervene, and there will be as a result cartilaginous or bony lesions, stulous passages, without reckoning all the chances of death which the t will encounter. The majority of surgeons make large incisions; others only an opening of a few centimetres, and place short and thick drainagein the opening. Arthrotomy is not urgent in white swelling, but it will nt the formation of fistulous passages, and the prolonged contact with already ed joint-tissues of a notable quantity of pus, which can only keep up and se the evil. Scooping the joint is only indicated in young subjects, for it give rise to endless suppuration in the adult. Recently, after very large ns, removal of the fungosities developed in the synovial membrane has been rmed. In the case of foreign bodies in the joint, arthrotomy is only indiwhen the pain and inconvenience are such that the patient requires it imtely; in all cases, it is superior to frequently repeated subcutaneous extracof which the ill-success is now thoroughly proved. Finally, in irreducible ions, it frequently occurs that a new joint is established in time. Incision is able to them, but M. Piéchaud confines it to the small joints. The method eration is as follows. The puncture, whether simple or aspiratory, is made a trocar, from one millimetre to one millimetre and a half in diameter, the being previously well soaped and washed with a 20 per cent. carbolized . The most prominent *cul-de-sac* is chosen; in the knee, for instance, the r internal one. It is important to avoid the cartilages and the bones, for lesion is sometimes, according to M. Broca, the starting point of *arthritis rmans*. The after-treatment consists in closing the little wound with a layer cinated collodion, and in immobilizing and compressing the joint under a wadding bandage. In arthrotomy, M. Piéchaud is an advocate of large openings. In order to determine the best situation in large joints attacked by effusion, an the method of operation which would allow easy sutures, he has undertaken a series of very interesting experiments. Of these, perhaps the most importa results are that the opening must be made outwards in the knee and the elbow, and in the shoulder backwards. When the capsule is opened, and the evacuati completed, the lesions of the deep portions are explored with the finger, dippe in carbolic acid; and when the synovial membrane still retains pus or adhere membranous fragments, the surfaces should be gently wiped with a small ne carbolized sponge to remove the adherent débris. The sutures should then b made, drainage affected, and Lister's dressing carefully applied.—*London Med. Record*, June 15, 1880.

Osteoplastic Resection of the Elbow-Joint.

Under this name, Dr. O. Völker describes in the *Deutsche Zeitschrift f Chirurgie*, Band 12, a temporary resection of the olecranon, the object of wh is to make the cavity of the elbow-joint freely accessible. He first perform the operation in a case of old imperfect lateral displacement of the left elbo joint, in a boy thirteen years old. The head of the radius projected on t radial side, and the inner condyle of the humerus on the ulnar side. The jo was almost stiff; and sensation and motion were considerably impaired in t region of the ulnar nerve. Before operating, Dr. Völker made an attempt reduction, but without success. Two parallel incisions were made along t sides of the olecranon, and were joined below by a transverse incision at the lo of the articulating surface of the radius; the bone was then sawn through. T adhesions of the ends of the joint to one another were then divided, partly b knife, partly by a blunt instrument; and the forearm could now be repla Two splinters of bone lying close to the ulnar nerve, and one which had bec adherent to the supratrochlear fossa, were removed; the olecranon was th brought into its normal position. The articulating surface of the head of radius, which projected a little, required removal. The wound was treated a septically, and healed without any other accident than the sloughing of a sm piece of skin. Four weeks after the operation, passive movements were co menced; the joint could soon be bent beyond a right angle, and almost co pletely extended, by the voluntary action of the patient. Pronation and supi tion were quite free, and the disturbances of the ulnar nerve had altogether d appeared. The result of the operation was thus perfect restoration of the fo and function of the joint. Dr. Völker believes that osteoplastic resection of elbow is indicated in cases of irreducible dislocation (recent and old), of forei bodies introduced into the joint, of broken-off pieces of articular cartilage a other substances lying free in the joint. He says that it is most important restore the bony union of the olcranon with the ulna. Antiseptic treatment the wound is indispensable; and cases in which the olecranon is not certai intact, as well as most cases of caries, are not fitted for the operation.—*Briti Medical Journal*, June 12, 1880.

Section of the Femur above Trochanter for Angular Anchylosis of Hip.

At a recent meeting of the Clinical Society of London (*Lancet*, May 29, 188 Mr. Barwell read notes of the following case: William D——, aged twelv had, when five years old, severe hip-disease and many abscesses about the joi After several years he got about on crutches, but the result was a thigh flexed right angles to the pelvis, and somewhat adducted. The deformity was extrem The altered state of parts about the neck of the bone rendered section at th e inadmissible; section below the trochanters was rejected because Mr. Bar- considers such operation must produce very considerable shortening, equal in unt to the distance from the centre of the head of the bone to a point below small trochanter—viz., from two to three inches. The operation of Rhea on and that of Lewis Sayre—viz., the removal of a wedge of bone from t the junction of the femoral neck and shaft—appears to him as an unattain- result, since an artificial joint at this part of the body, even if it could be ed, could not be relied on to support the weight of the trunk. A review of esults obtained by these surgeons shows that of the two successful cases— of Barton's and one of Sayre's—motion at the place of section was either r attained or soon ceased. In the case of William D—— all such intention therefore, discarded. Mr. Barwell endeavoured simply to secure a straight without further shortening than that already produced by the loss of growth h accompanied the original disease.

e operation was performed antiseptically on Oct. 30th, by making a crucial ion on the outer aspect of the great trochanter down to the bone, peeling off eriosteum all round, finding the small trochanter and the tendon of the ilio- muscle, passing above this latter part an armed needle, and drawing with thread round the bone a chain-saw, with which, obliquely upward and out- , the section was made. Barely twenty drops of blood were lost. The nt was taken to bed, and a weight suspended to the foot. No suppuration fol- d, nor indeed any other bad symptom, the temperature being good throughout. n of soft parts took place by first intention, except where the drainage-tube was ted, and that channel healed as soon as the drain was withdrawn. *Result:* boy stands upright and straight; the limb parallel with the other; the short- is barely an inch, and that appears due to lack of growth in the bone, not e operation. He walks almost perfectly, and without sway of the body. Barwell especially directed attention to the fact that this end was attained n operation which, being subperiosteal, secured so rapid a union of bone that oy was in bed only thirty-three days. The temper and the small size of cal needles gave rise to a little difficulty in getting a thread round the bone. nstrument devised on the principle of Bellocq's sound was exhibited by Mr. ell, the use of which renders the operation quite easy.

r. HEATH said that in cases where it could be applied Mr. Adams's plan not be improved on; but there were cases where Mr. Barwell's method advantageous—*e. g.*, in a woman he has now under care, who has had chronic disease from early childhood, and in whom it is impossible to define the neck e femur. Division between the trochanters is better than Mr. Gant's method ection below them, owing to the tilting of the bone by the psoas muscle. n in London, Dr. Sayre showed a model of the preparation from his case, t hardly seemed an accurate representation, so perfect was the joint. Be- , it is doubtful whether a stiff limb be not preferable to a joint in that situa- .

reatment of Club-Foot by Excision of a Wedge-shaped Portion of Bone.

he following cases are reported by KÖNIG, in the *Centralblatt für Chirurgie*, 13, 1880. A lad, aged 12, had been affected for about four years with dou- equino-varus of paralytic origin. There was extreme contracture in each er extremity; the extremity of each foot was considerably adducted, and there much arching of the sole, especially in the region corresponding to the junc- of the scaphoid and cuneiform bones. The toes were much depressed, in sequence rather of distortion of the metacarpus than of plantar flexion of the le foot. The patient was unable to move about, save with extreme difficulty, and on the tips of the outer toes. An unsuccessful attempt having been made to relieve this deformity, by dividing the plantar aponeurosis, Prof. König performed the following operation, first on the left, and two months later on the right foot. The extremity having been rendered bloodless, an oblique incision was made along the dorsum of the foot, and then, after the tendons and soft parts had been detached from the metacarpus, and dragged aside, a wedge of bone was removed, containing the cuboid, the scaphoid, and most of the caput tali. The anterior portion of the foot could at once be restored to its normal position. The healing of the wound after this operation was retarded. in consequence of sloughing of two extensor tendons and a portion of integument. In the operation on the right foot, a straight incision about three inches and a quarter in length was made along the outer portion of the dorsum. The removed osseous wedge included large portions of the scaphoid and cuboid bones, and portions also of the cuneiform bones. The patient made a good recovery, and at the end of a few months was able, with suitable boots, to walk well.

The subject of the second case was a girl, aged 13, affected with double congenital club-foot. The normal shape of the left foot had been established through ordinary treatment, whilst the right foot remained in a condition of extreme and obstinate equino-varus. The outer margin of the dorsum was the only portion of the extremity that could be put to the ground. There were a marked prominence in the region of the cuboid bone, and a deep angular depression on the corresponding portion of the inner margin of the foot. A long incision having been made over the prominent cuboid bone, and the soft parts displaced, a wedge of bone was removed, the base being formed by the outer surface of the cuboid, and the apex by the inner portion of the scaphoid. This patient progressed favourably until the tenth day, when she died suddenly from collapse. The necropsy revealed signs of old and extensive valvular disease of the heart, recent ulcerative endocarditis, and consecutive pulmonary changes of old and recent date.

The third case was one of extreme equino-varus of the right foot of a man aged 19. The deformity had resulted from an injury to the extremity when the patient was five years old. The affected foot presented the characters of a paralytic equino-varus. The whole of the left extremity was incompletely developed and smaller than its fellow. The pointing of the toes in this case also was due to flexion of the anterior portion of the foot, through displacement of the scaphoid and cuboid bones. There was extreme adduction. On the outer portion of the dorsum was a marked prominence, formed by the completely luxated caput tali. Twisting of the foot was less marked than adduction and pointing of the toes. The patient walked with difficulty, and chiefly on the prominent caput tali and the fifth metatarsal bone. An incision was made along the outer portion of the dorsum, and a large wedge-shaped portion of bone removed with the chisel, including the dislocated process of the astragalus, and a large piece of the anterior process of the os calcis. The foot could now be adducted, but the pointing of the foot still persisted. It was necessary therefore to make a second incision, the foot being very broad, and to remove through this a portion of the scaphoid bone. After removal of some small projecting pieces of bone, the foot could be placed in a good position.

In some comments on these cases, Professor König concludes that excision of an osseous wedge from the dorsum of the foot is the surest and safest method with a neglected and disabled talipes, whether of the paralytic or the congenital form. Amputation in such cases would now seem to be hardly justifiable. This treatment, it is held, is safer than the method of forcible stretching, formerly practised and advocated by the author. The latter can be serviceable only in certain cases, and, when followed at once by the application of a plaster-of-Paris andage, might result in gangrene of the extremity. The treatment by excision f a wedge of bone is more readily indicated, and, as is shown by the first case, ay serve in rendering a badly paralyzed foot a relatively useful limb. This ethod is believed to be quite safe; of course Professor König states, with anti-eptic precautions. In the second case death was due, not directly to the opera-ion, but to heart-disease and consequent pulmonary changes.

The excision of the osseous wedge must be so practised on the dorsum of the oot that, in correspondence with the adduction of the anterior portion of the oot on the one hand, and with the pointing of the toes on the other, the removed ortion of bone must be broader at its upper and outer portion. As a rule, the isel should be applied so as to remove the most prominent part of the dorsum f the distorted metatarsus. In congenital talipes, the head and neck of the tragalus with the cuboid bone, and, where the foot is pointed, the scaphoid one, have usually to be involved in the operation. In paralytic talipes, the edge should be taken more from the anterior portion of the foot. A small wedge f bone is to be first taken from the outer portion of the metatarsus, either with strong knife or with a chisel, and afterwards more bone from the middle of the ot. Before the foot can be well straightened, it is often necessary to chip away veral small pieces of bone. The only joint which the surgeon has to avoid is that f the ankle. A longitudinal incision, carried over the most prominent portion of one, is to be preferred, Professor König thinks, to the oblique incision. The tter affords more room, but would probably necessitate division of some of the ndons, and favour the occurrence of sloughing. If a second incision be needed, is should be made parallel to the first. The soft parts are next detached from e bones and joints, and held to one side. In a case of extreme talipes equinus would be well to divide the tendo Achillis. Occasionally, as in the first of nig's reported cases, it may be found necessary to divide also the plantar oneurosis.—*London Med. Record*, June 15, 1880.

Midwifery and Gynæcology.

Two Cases of Extra-uterine Fœtation, with Results.

At a late meeting of the Obstetrical Society of London (*British Med. Journal*, ne 26, 1880) Dr. CHARLES H. CARTER related these cases. The first patient, ed 38, was admitted as an urgent case of extra-uterine fœtation. She was in very critical state; pulse 150. There was a tumour toward the right side as gh as the umbilicus, and continuous with a soft doughy mass occupying the pouch f Douglas. Menses had ceased, and she had supposed herself pregnant, in ecember, 1878. In April, 1879, she was in St. Bartholomew's Hospital under r. Matthews Duncan, with supposed retroversion of the gravid uterus; and an ttempt was made to push up the swelling. At the end of August she passed a rge substance by the vagina; and was readmitted in September. Extra-uterine etation was then diagnosed, the fœtal heart having been heard on her first coming o the out-patient room, but afterwards ceasing. The uterine probe entered six ches into the abdominal hardness, and the point felt as if less than the thick-ess of the unimpregnated uterine-wall covered it. The patient left against dvice. A fortnight before her admission under the author on January 13th, 1880, she was seized with abdominal pain. A superficial abscess, pointing near the umbilicus, was opened on the 26th, and fetid pus and *débris* let out. On February 12th, a piece of bone was felt by a probe; the opening was enlarged and the fœtus extracted. The placenta did not come away with the fœtus, and the discharge was very offensive for three days. A discharge took place per *vaginam* on the 23d, and the patient afterwards quickly recovered.

The second patient, aged 34, was admitted in July, 1879, for what was sup posed to be pelvic cellulitis. The uterus was fixed, and there was a swelling o the left side up and about an inch above the iliac crest. She went out on Oc tober 8th, the swelling being smaller. At the end of October, some fœtal bo were passed *per rectum*, and she was readmitted in December. Discharge o bones went on until May, when some large flat pieces were nipped in two a extracted. The author thought that, if he had diagnosed this case in the earli stage, he should have been justified in endeavouring to evacuate the cyst throu the abdomen.

The Prophylactic Washing Out of the Uterus with Carbolic Lotion after Delivery.

Professor Stadfeldt, of Copenhagen, contributes a paper on this subject No. 7 of the *Centralblatt für Gynäkologie*, 1880. He states that the previo communication in No. 5 of the *Centralblatt* (reported by us in the *Medical Ne and Abstract* for May, 1880, p. 302) led him to communicate some observatio on the application of an antiseptic treatment modified to suit lying-in wome The author has employed this method since 1870 with ever-increasing energ and communicated a paper on "Maternities, their Organization and Administ tion," to the Brussels Congress, in which he publishes his experiences. In th communication the author was able to state, that in the quinquennium 1870– the mortality in the Copenhagen University lying-in institution had been reduc to 1 in 87, whilst the majority during the three previous quinquennia varied fr 1 in 37 to 1 in 14, and had at no single quinquennium during the long existe of the institution been nearly so low. The relation is still more favourable the last quinquennium 1875–79, since of 5098 lying-in women only 44 died puerperal fever, *i. e.*, 1 in 116. This result the author considers more favoura than can be presented by any similar lying-in institution which receives patie from all the hospital quarters of a town, as well as from the workhouses, in whi primiparæ are decidedly in the majority. The author contends, that not o the mortality but the morbility of the patients is diminished by the antisep precautions. The method adopted by the author is methodical washing out the vagina before delivery, the application of carbolic vapour spray during t delivery, and intra-uterine injections with carbolic lotion after delivery. T author expresses his astonishment that the application of carbolic spray has fou so little acceptance in lying-in institutions, stating that in the Copenhagen M ternity it has been four years in use for every labour, without having caused a injurious results to mother or child. He states, also, that its application cau so little trouble that he cannot see why a method so reasonable for a lying- institution should be summarily pushed aside. The spray must be commenc from the moment when the parts of the child begin to show themselves at t vulva until any tears which may have occurred during the delivery in the vul are united by suture, and the genital opening is covered with a layer of prepar jute. The intra-uterine washings after delivery have been found specially bene ficial under certain conditions, although he has only used three p. c. solution, b in large quantity. He has never observed any evil results from these injectio in hundreds of cases. He does not recommend such injections in every cas however, but only when the hand or instruments have been introduced into th passages, or when remains of membranes have been retained in the uturus. A brief account of twelve cases is given in support of the advantage derivable from the use of intra-uterine injections.—*Edinburgh Med. Journal*, June, 1880.

Typhoid Fever during Pregnancy and the Puerperal State.

Prof. Gusserow, in a recent paper (*Berlin. Klin. Wochenschrift*, No. 17, 1880), offers some interesting and valuable information on the relations of that ubiquitous disease to the puerperal state.

He premises that typhoid fever is comparatively rare in pregnant women, especially in the later months of pregnancy, probably because they are less liable to be exposed than healthy women. The statistics we possess on this subject are at present very scanty. At Basle, out of 1420 typhoid cases, 18, or 12 per 1000, were in pregnant women; while at Vienna, out of 1852 cases, only 24, or 13 per 1000, occurred in them. At Basle abortion occurred in 83 per cent. of the cases observed; at Vienna in only 58 per cent., the treatment adopted, as will be presently shown, having an essential influence on its production. The mechanism f the abortion in the early months of pregnancy is not absolutely clear; changes the placenta and decidua may result from the maternal illness, and so cause e death and casting off of the fœtus. There is absolutely no proof whatever, any case, of the occurrence of intra-uterine disease in the fœtus itself. Proessor Gusserow has examined a number of fœtuses from typhoid women who ave aborted, without ever finding a trace of alteration in the bowel, spleen, or ewhere that could be referred to a typhoid origin. The great cause of aboron in typhoid fever appears to be a high temperature of the maternal blood. rom Professor Gusserow's own observations, as well as from those of Hueter, iedler, Kaminsky, Georgi, and Winkel, there can be no doubt that the life of e fœtus is in danger as soon as the temperature of the mother exceeds 39° cent., at the danger becomes very great when it reaches 40°, and that the child invitably dies if 41° to 41.5° be attained. The effect of high temperature is eater the longer it lasts; the fœtus may tolerate a temperature of 40°, or ven 40.5° for a short time, while a protracted temperature of 39° may be fatal it. Briefly stated, the danger to the fœtus is proportional to the duration and e height of the maternal temperature. Hence most cases of fœtal death cur in the second and third weeks of the fever. But abortion may take place uring typhoid fever without the previous death of the fœtus, uterine contraction eing the primary phenomenon. Such cases appear to be not very uncommon, d here also the exciting cause seems to be a long-continued action of high temeratures. Most often Professor Gusserow has observed the occurrence of this free rm when the fever has kept for several days above 40° cent. with scarcely any emission, and, even where the birth-pains apparently begin during early conalescence, a careful analysis of such cases generally shows that their real comencement was before the end of the febrile period.

But there are some cases in which the exact connection between temperature d uterine action is difficult to make out. In these there is a severe rigor, with udden increase of fever, followed by the pains of labour, the act of birth being free from excessive hemorrhage, and not unusually prolonged. Rigors, as Professor Gusserow points out, are unusual during the ordinary course of typhoid fever, nor can they be regarded, in the present state of our knowledge, as the result of the commencement of parturition, any more than the occurrence of uterine pains can be referred with certainty to the passing elevation of temperature which accompanies the rigor. At present these phenomena must be considered in the light of an unsolved riddle. The prognosis of abortion in typhoid fever depends on the period of pregnancy, and on the period of the fever at which it occurs.

During the first three months of pregnancy severe hemorrhage is liable to accompany the act, and the patient's life may be endangered by the loss of blood. Possibly some typhoid alteration of the uterine membranes may be present to account for it. In the later months the delivery is but little diverted from its normal course by the concomitant fever. For the patient, however, it is all-important at what time during the febrile period the delivery occurs. Her best chance is for it to take place very early in the course of the typhoid. When it comes—as, unfortunately, it generally does—at the height of the fever, or in the beginning of convalescence, the prognosis, for obvious reasons, is unfavourable. Professor Gusserow's experience, also, is that these patients are more liable to puerperal infection than other women. In concluding his lecture he illustrates by typical cases the difficulty of distinguishing between the early stages of typhoi fever at the time of childbed, and puerperal fever. The two affections may, very rarely, exist in combination. The diagnosis rests on the irregular tempera ture and absence of a dicrotous pulse, of roseola, and of diarrhœa in puerpera fever, as well as on the condition of the uterus and its appendages, and of th lochial discharge. Splenic enlargement is common to both diseases, and is ofte difficult to make out in puerperal women. Owing to the protean character the symptoms both of typhoid and puerperal fever, the differential diagnosis ma in some cases be a long time undecided. As to treatment: since the height the fever is the main element in inducing abortion in pregnant women, the energetic use of antipyretic remedies is urgently indicated. Professor Gusserow h always of late treated both pregnant and parturient women with cold baths, wi the best results. The artificial induction of labour in typhoid fever he regar as an error, and to be avoided.—*Med. Times and Gazette*, June 26, 1880.

Septicæmia from an Ovarian Cyst.

Dr. VINCENZIO (*Annali Universali di Medicina e Chirurgia*, Feb. 188 relates an interesting case of suppuration of an ovarian cyst after tapping. T symptoms commenced about twenty-four hours after the operation, and gradual became worse, until the patient was in a condition of extreme danger. T temperature was 100.75 Fahr., pulse 120, respiration 36. The symptoms a appearances were such that there could be no possibility of doubt as to the dia nosis, nor yet as to the treatment. The author undertook the operation with th more confidence, owing to the successful result of a similar case in the hands Dr. Peruzzi (*Raccoglitore Medico di Forli*, series iv. vol. iv. 1875) and other The chief features of difficulty in the case were the purulent nature of the contents of the cyst, and the thinness of its walls. An incision, nearly four inche in length, was made in the linea alba, extending to within four-fifths of an inc of the umbilicus. Spencer Wells's trocar was used, and about two gallons extremely fetid pus were drawn off through it, but unfortunately a large quantity escaped into the peritoneal cavity, and especially into the inguinal fossa. This necessitated a thorough cleansing of the parts, by which a delay of half an hou was incurred. The peduncle was large and flattened, and lay chiefly to the le side. The external wound was brought together with five deep metal sutures, and six superficial ones of carbolized silk. The strictest antiseptic precautions were employed throughout. Recovery took place somewhat slowly, partly in consequence of continual disturbances of the bowels, and partly of the extreme state of exhaustion to which the patient had been reduced previously to the operation.—*Lond. Med. Record*, June 15, 1880.

MEDICAL NEWS.

Ovariotomy.

On June 11th, Mr. Spencer Wells performed ovariotomy for the one thousandth time. When we remember how many thousand hours of thought and anxiety, in addition to direct surgical labour, this unparalleled feat represents, we may well admire the completion of a Herculean task; yet sober reasoning gives us yet more cause to admire its commencement, both as a credit to surgical science and to the great contemporary operator himself. The thousandth case was the brilliant consummation, under relatively easy conditions, of a struggle commenced under diametrically different auspices.

Let us bear in mind what the word ovariotomy implied when it caught the ear of any surgeon in December, 1857; then let us reflect on the present position of the operation. In addition to Mr. Wells's long list of cases, we have long tables of statistics of operations by other surgeons, which, but for Mr. Wells's example, might have been, at the least, much shorter. Fairness leaves us room for but one opinion as to whom honour and credit are due.

In 1857, forty-eight years had elapsed since McDowell first performed ovariotomy. This was an accomplished fact; there cannot be a second first, and none have offered more homage to the memory of the American than Mr. Wells himself. But that which McDowell originated was, till then, taken up by others always with diffidence and timidity, and never with sufficient success to impress surgical society with confidence. McDowell stands to Spencer Wells in the same relation as Solomon de Caus, the Marquis of Worcester, Papin, and Savery bear to James Watt. In 1857, the operation had fallen into absolute disrepute; as Dr. Keith admitted once in these pages: "Ovariotomy was then, as an operation, simply nowhere." Dr. Clay had achieved fair success in the provinces, yet somehow he failed to inspire confidence among either provincial or metropolitan surgeons, and thus to really establish ovariotomy as a justifiable operation. In spite of all his skill and foresight, Baker Brown had met with so many failures that he was threatened with an inquest on his next fatal case, and had not operated for two years when Mr. Wells began. Liston had stigmatized ovariotomists as "belly-rippers;" Lawrence and other great hospital surgeons were indefatigable in throwing discredit on them.

Besides great personal supervision of the minutest points of general after-treatment, Mr. Wells at once set in practice and strenuously advocated certain details of manipulation and of therapeutics, previously more or less disregarded. He discarded the plan of tying the pedicle and leaving the ends of the ligature hanging out through the wound. He shortened the incision in the abdominal wall, and emptied the cyst before attempting to draw it out. He substituted extra- for intra-peritoneal treatment of the pedicle, and did not recur to this intra-peritoneal method until antiseptics altered the whole position of the operation. He took great care to include the peritoneum in the sutures uniting the abdominal wound—a practice based on scientific experimental evidence, visibly demonstrated by his preparations showing the effects of sutures in uniting abdominal wounds in animals, now in the museum of the College of Surgeons. He did not insist on the administration of opium after operation, unless it were strongly indicated; and he objected to the operation chamber being kept at a stifling temperature. Again: he made his subject scientific. Apart from free publicity of statistics before the Royal Medical and Chirurgical Society, he exhibited before the Pathological Society not only specimens which illustrated anomalies in ovarian disease, and rarities in the way of pelvic tumours, for which every operator must be prepared, but every tumour which he removed, whatever the result was, until the operation was thoroughly recognized as legitimate.

What are the fruits of all this labour, beyond all that is implied in the completion of one thousand cases? Out of Mr. Wells's first five hundred cases, three hundred and seventy-three recovered and one hundred and twenty-seven died—a mortality of 25.4 per cent. Great practical results had already followed his efforts; and several imitators had commenced to practise ovariotomy with his precautions, and had achieved success. Of the next three hundred cases, two hundred and twenty-three recovered and seventy-seven died—a mortality of 25.6 per cent. Eighty-three recovered out of the next one hundred cases, and seventeen, or 17 per cent., died. During the last two years that Mr. Wells operated at the Samaritan Hospital, the real battle-ground of his victories, 90 per cent. of his hospital cases were cured. Lastly: of the concluding hundred cases, eighty-nine have recovered and eleven, or 11 per cent., died. In 1878, shortly before the completion of nine hundred cases, he had adopted antiseptic precautions. The grand total shows seven hundred and sixty-eight recoveries and two hundred and thirty-two deaths—a mortality of 23.2 per cent.; but, of course, to judge these statistics fairly, the low mortality of 11 per cent. in the last hundred must, in the present state of the operation under antiseptic precautions, be taken as an average which we may hope to see still further diminished; and, in justice to the operator, we must not forget that, for obvious reasons, many of the later cases have been highly complicated, other surgeons having undertaken many simpler cases which, a few years back, would have been referred to Mr. Wells.

Lord Selborne, in a public address, once demonstrated how the recovery of three hundred and seventy-three patients out of Mr. Wells's first five hundred cases represented a total gain of 10,817 years of human life. By the same calculation, multiplying the 768 recoveries by 29, the insurance "life expectancy" number, we find that 22,272 years of human life may be estimated as having been added to society by the direct agency of Mr. Spencer Wells. On this and the above observations comment is needless. Without disparaging either the past introducer or the present perfectors of ovariotomy, Mr. Spencer Wells has rescued the operation from the discredit into which it had fallen, and established it, in the opinion of the profession here and abroad, as a thoroughly legitimate and marvellously successful surgical operation.—*Brit. Med. Journ.*, June 19, 1880.

American Medical College Association's Requisite for Graduation.—At the late meeting of the American Medical College Association an amendment to the Articles of Confederation was adopted, requiring its members to exact of all candidates for the degree of M.D. attendance upon three courses of at least twenty weeks each during three distinct years, as the condition for conferring the degree. Of the twenty-five colleges composing the Association, twenty voted in the affirmative, one declined to vote, and four were not represented.

Medical Society of New Jersey.—The one hundred and fourteenth annual meeting of this Society was held at Princeton May 25th and 26th, Dr. A. W. Rogers, of Paterson, President, in the chair. The following office bearers were elected for the ensuing year: President, A. N. Dougherty, M.D., of Newark; Vice-Presidents, Drs. L. W. Oakley, of Elizabeth, John W. Snowden, of Waterford, and S. Wickes, of Orange; Secretary, Dr. Wm. Elmer, Jr., of Trenton. The next meeting will be held at Long Branch.

Ohio State Medical Society held its thirty-fifth annual meeting at Cleveland June 15th and 16th, Dr. J. A. Murphy, of Cincinnati, President, in the chair.

The following office bearers were elected for the ensuing year: President, E. H. Hyatt, M.D., of Delaware; Vice-Presidents, Drs. Cyrus Falconer, of Hamilton, J. C. Hubbard, of Ashtabula, R. L. Sweeny, of Marion, and H. J. Donahue, of Sandusky; Secretary, Dr. J. F. Baldwin, of Columbus. The next meeting will be held at Columbus.

Rhode Island Medical Society held its annual meeting at Providence June 9th, Dr. Edward T. Caswell, of Providence, President, in the chair. The Fiske-Fund Prize Committee reported that the prize of $200 had been awarded to Dr. Charles V. Chapin, of Providence, for an unusually meritorious essay on "The Sympathetic Nerve in its Relation to Disease."

The following officers were elected for the ensuing year: President, Charles O'Leary, M.D.; Vice-Presidents, Drs. Job Kenyon, and O. C. Wiggin; Secretary, Dr. V. O. Hardon, all of Providence.

Texas State Medical Association held its twelfth annual session at Brenham, Washington County, April 6th, Dr. John H. Pope, of Marshall, President, in the chair. The following officers were elected for the ensuing year: President, Dr. A. R. Kilpatrick, of Navasota; Vice-Presidents, Drs. R. M. Swearingen, of Austin, E. J. Beale, of Fort Worth, and O. H. Seeds, of Columbia; Secretary, Dr. R. H. L. Bibb, of Austin. The next meeting will be held at Waco on the first Tuesday of April, 1881.

Ophthalmological Society of Great Britain.—On the evening of June 23, a meeting of the leading ophthalmic surgeons of the United Kingdom was held in London to organize an ophthalmological society. Mr. Bowman occupied the chair. It was determined to institute the "Ophthalmological Society of the United Kingdom," which should meet about five times a year, ordinarily in London, and that the Society should publish *Transactions*. Mr. Bowman was elected President of the Society.

Personal.—At a congregation held on the 10th of June at Cambridge, England, the honorary degree of Doctor of Laws was granted to the following gentlemen on the occasion of the proposed meeting of the British Medical Association at Cambridge in August: Dr. Paul Broca, of Paris; Dr. C. E. Brown-Séquard, F.R.S., of Paris; Dr. Chauveau, of Lyons; Dr. F. C. Donders, of Utrecht; Dr. S. D. Gross, of Philadelphia; Sir William Jenner, K.C.B., M.D., F.R.S.; Sir William Gull, M.D., F.R.S.; Sir George Burrows, M.D., F.R.S.; Mr. William Bowman, F.R.S., of London; Rev. S. Haughton, M.D., F.R.S., of Dublin; Mr. Joseph Lister, F.R.S., of London; Dr. Denis C. O'Connor, President of the British Medical Association; Mr. John Simon, C.B., F.R.S., of London; Dr. Andrew Wood, M.D., F.R.S.E., of Edinburgh.

The selection made by the University of Cambridge of a representative of the medical profession of America, upon whom to confer its degree of Doctor of Laws, will be universally conceded as eminently fit. It will be remembered that a few years ago, upon the occasion of his last visit to Europe, the University of Oxford conferred upon Dr. Gross its degree of Doctor of Civil Laws, and now, after having received the degree of LL.D. Cantabriensis, he will enjoy, among the many marks of distinction which have been conferred upon him, the rare honour of being an alumnus of the two most ancient and learned universities of Great Britain, and of having received from them their highest honours.

The honorary degrees will be conferred in the Senate House, at Cambridge, on the 11th of August, at 12.30 P. M., upon which occasion Dr. Gross will be present.

American Dermatological Society will hold its fourth annual meeting at th
Ocean House, Newport, on the 31st day of August.

Prizes.—The Boylston Medical Committee have voted this year's prize of o
hundred and fifty dollars to W. Watson Cheyne, F.R.C.S., Assistant Surgeon
King's College Hospital, London, for a dissertation on "Antiseptic Treatment:
What are its Essential Details? How are they best carried out in Practic
Form?" and in view of the great excellence of this dissertation the committe
voted that there be added to their award the Boylston Prize Gold Medal.

The following are the questions proposed for the prize ($300) for 1881:—

I. The Effects of Drugs, during lactation, on either nurse or nursling.

II. Injuries to the Back, without apparent mechanical lesion, in their surgic
and medico-legal aspects.

The following are questions proposed for 1882:—

I. Sewer Gas: What are its physiological effects on animals and plants. ($30
will be paid to the author of the successful dissertation on this subject.)

II. The Therapeutical Value of Food, administered against, or beyond, t
patient's appetite and inclination. (A premium of $200 will be paid to t
author of the successful dissertation on this subject.)

The Cartwright Prize ($500) of the Alumni Association of the College
Physicians and Surgeons, New York, will be awarded after February 1, 18
to the best essay on some subject in medicine or surgery. The prize is open
only the Alumni of the College, and the essay must present sufficient origi
experimental or clinical observation to make it a useful contribution to medicin

The directions as to the mode of transmission of competing essays for the
prizes will be found on pages 304 and 298 of the July number of the *Americ
Journal of the Medical Sciences.*

Literary Notes.—Dr. Harris's elaborate article on the Porro Operation, whi
appeared in the April number of the *American Journal of the Medical Science*
has been translated and republished in full in the number of the *Annali Univ
sali di Medicina e Chirurgia* just received.

OBITUARY RECORD.—At Washington, D. C., on the 7th of June, aged 7
JAMES CROWDHILL HALL, M.D., formerly Professor of Surgery in the Medic
Department of Columbian University.

Dr. Hall was a native of Alexandria, Va., and graduated in medicine at t
University of Pennsylvania in 1827. He was prominent in the performance
both his professional and civic duties. He is said to have been physician to
of the Presidents from Jackson to Lincoln, and to most, if not all, of the forei
ministers resident in Washington during that period. He was actively identifi
with all the local medical charities of Washington, and was President of t
Trustees of the Corcoran Art Gallery, and on the occasion of the reception giv
by that body to the Pharmacopœia Convention in May last, he personally receiv
the delegates, and his courteous and dignified manners and well-stored fund
information did much to enhance the pleasure experienced in examining t
beautiful art collection. Ripe in years and full of honour he has been gather
unto his fathers, leaving a record which will be long held in loving memory by
his fellow-townsmen.

---

*To Readers and Correspondents.—The editor will be happy to receive early
intelligence of local events of general medical interest, or which it is desirable
to bring to the notice of the profession. Local papers containing reports or
news items should be marked.*

NEW MEDICAL BOOKS—Just Ready.

EMMET'S GYNÆCOLOGY—New Edition.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the Use of Students and Practitioners of Medicine. By THOMAS ADDIS EMMET, M.D., Surgeon to the Woman's Hospital of the State of New York, etc. Second edition, thoroughly revised. In one very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; very handsome half Russia, $6 50.

The appearance of a second edition of this work so short a period, justifies the high estimate we laced upon its merits. The favorable reception ac-rded to this work abroad must be an additional atification to the author, as it must be considered e highest testimony to its merits. The high en-miums generally bestowed by the British and ropean journals bear witness to the fact that Dr. met's work is a valuable and worthy addition to erican medical literature.—*Am. Journ. of Med. iences*, July, 1880.

We congratulate both the author and the profession upon the degree of appreciation that the work has secured. In its present form, the book stands as a monument of the life-long devotion of a man of rare capacity to a field of practice which, when he entered upon it, had been but little cultivated in this country. It is certain that, in no small degree, its present glories are due to his individual efforts. This ripe and formal embodiment of his views cannot fail to be far-reaching in its influence upon future doctrine and practice.—*N. Y. Med. Journ.*, July, 1880.

FOSTER'S PHYSIOLOGY—Revised Edition.

TEXT-BOOK OF PHYSIOLOGY. By MICHAEL FOSTER, M.D., F.R.S., Prof. of Physiology in Cambridge Univ., England. A new American from the third English edition. Edited, with extensive notes and additions, by EDWARD T. REICHERT, M.D., Demonstrator of Experimental Therapeutics in Univ. of Penna. In one handsome royal 12mo. volume of 1030 pages, with 259 illustrations. Cloth, $1 50; leather, $2 00.

he additions of the American editor are so copi-s and important as to largely increase the book's here of usefulness. In notices of former editions, alluded to the absence of any reference to the ysiological anatomy of the different organs, and e dearth of illustrations as serious drawbacks to value and general usefulness of Dr. Foster's rk. These faults of omission have been intelli-ntly and quite fully supplied by the American editor. So ably and so thoroughly has the editor performed his task, that we have no hesitancy in saying that, in our opinion, the American edition is far superior to its English contemporary. In its present form we confidently recommend this text-book to the student as a clear, concise, and thoroughly reliable exposition of modern physiology.—*Am. Journ. of Med. Sciences*, July, 1880.

E SAME. English Student's edition. In one small 12mo. volume of 804 pages, with 72 illustrations. Cloth, 75 cents.

CORNIL & RANVIER'S PATHOLOGICAL HISTOLOGY.

ANUAL OF PATHOLOGICAL HISTOLOGY. By V. CORNIL, Prof. in the Faculty of Medicine of Paris, and L. RANVIER, Prof. in the College of France. Translated, with notes and additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surgeon to the Philada. Hospital, etc., and HENRY C. SIMES, M.D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; very handsome half Russia, $7.

NETTLESHIP ON THE EYE.

E STUDENT'S GUIDE TO DISEASES OF THE EYE. By Mr. NETTLESHIP, Ophthalmic Surgeon to St. Thomas's Hospital, London. In one neat royal 12mo. volume of 370 pages, with 89 illustrations. Cloth, $2.

MORRIS ON SKIN DISEASES.

IN DISEASES; INCLUDING THEIR DEFINITION, SYMPTOMS, DIAGNOSIS, PROGNOSIS, MORBID ANATOMY, AND TREATMENT. A Manual for Students and Practitioners. By MALCOLM MORRIS, M.D., Joint Lecturer on Dermatology at St. Mary's Hospital Medical School. In one 12mo. volume of over 300 pages, with illustrations. Cloth, $1 75.

GREENE'S MANUAL OF MEDICAL CHEMISTRY.

A MANUAL OF MEDICAL CHEMISTRY. By WILLIAM H. GREENE, M.D., Demonstrator of Chemistry in the Medical Department University of Pennsylvania. For the Use of Students. Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages, with illustrations. Cloth, $1 75.

SOLD ONLY BY SUBSCRIPTION.

REYNOLDS'S SYSTEM OF MEDICINE. Revised Edition. Complete in 3 Vols.

A SYSTEM OF MEDICINE. Edited by J. RUSSELL REYNOLDS, M.D., Prof. of the Principles and Practice of Medicine in University College, London. With notes and additions by HENRY HARTSHORNE, M.D., late Prof. of Hygiene in the Univ. of Penna. In three large and handsome royal octavo volumes, containing 3052 closely printed double-column pages, with 317 illustrations.

HENRY C. LEA'S SON & CO., Philadelphia.

NOTICE TO SUBSCRIBERS.

INCREASED INDUCEMENTS FOR 1880.

With a view of increasing the attractions of the "American Journal of the Medical Sciences," and of bringing within the reach of all members of the profession the immense amount of information now presented by it and its accessory periodicals, the "Medical News and Library" and the "Monthly Abstract," the two latter will hereafter be merged together, under the name of "The Medical News and Abstract," commencing January 1, 1880. The "News and Abstract" will consist of sixty-four pages per month, handsomely printed, in a neat cover, and will contain all the material heretofore presented in both periodicals, with the exception of the sixteen pages of the "Library Department." Its price will be Two Dollars and a Half per annum, invariably in advance, at which rate subscribers will receive nearly *eight hundred large octavo pages per annum*, free of postage.

Not only will this monthly thus be in itself one of the cheapest periodicals offered to the profession, but it will be furnished in commutation, without charge, to advance-paying subscribers of the "American Journal of the Medical Sciences," the subscription to which will remain, as heretofore, Five Dollars per annum. For this very moderate sum, therefore, subscribers will receive two periodicals of the highest class, a Quarterly and a Monthly, containing in all nearly two thousand pages per annum, stored with the choicest original and selected matter that can be furnished by the medical literature of both hemispheres.

These terms may be recapitulated as follows:—

TERMS FOR 1880.

The American Journal of the Medical Sciences, published quarterly (1150 pages per annum), and The Medical News and Abstract, published monthly (768 pages per annum),	**Five Dollars per annum, in advance.**

SEPARATE SUBSCRIPTIONS TO

The American Journal of the Medical Sciences, when not paid for in advance.	**Five Dollars.**

The Medical News and Abstract, invariably in advance, **Two Dollars and a Half.**

⁂ Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the Journal (two annually) and the News and Abstract (one annually), free by mail, on remitting ten cents for each cover.

It is evident that only a very considerable increase to the existing subscription list will justify the unexampled terms thus offered, by which the equivalent of three or four large octavo volumes is furnished, handsomely printed in a form for preservation, for the trifling sum of Five Dollars. Gentlemen, therefore, are respectfully requested to lose no time in remitting their subscriptions, to avoid the risk of disappointment from the exhaustion of the edition printed; and it is suggested that they may aid in rendering the enterprise permanent by kindly communicating to their friends the very great inducements thus offered.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "Journal" and "News and Abstract" may be made at the risk of the publishers by forwarding in registered letters. Address

ABSTRACT.

A CONSOLIDATION OF THE "MEDICAL NEWS AND LIBRARY" AND THE "MONTHLY ABSTRACT OF MEDICAL SCIENCE."

EDITED BY

I. MINIS HAYS, A.M., M.D.

PHILADELPHIA:
HENRY C. LEA'S SON & CO
1880.

Published Monthly at $2.50 per annum in Advance.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

ered according to the Act of Congress, in the year 1880, by Henry C. Lea's Son & Co., in the Office of the Librarian of Congress. All rights reserved.

NEW BOOKS AND NEW EDITIONS.

BARTHOLOW'S MEDICAL ELECTRICITY—Shortly.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATIONS TO MEDICI By Roberts Bartholow, A M., M D., LL.D., Professor of Materia Medica and Ge Therapeutics in the Jefferson Medical College of Philada. In one very handsome oc volume of about 450 pages, with illustrations.

RICHARDSON'S PREVENTIVE MEDICINE—Shortly.

PREVENTIVE MEDICINE. By Benjamin Richardson, M.D., F.R.S., M.A., LL D., F.S Fellow of the Royal College of Physicians, London. In one octavo volume of about 5

THOMAS ON WOMEN—New and Revised Edition—Nearly Ready.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. Gaillard Th M.D., Prof. of Obstetrics, etc., in the College of Physicians and Surgeons, New Y Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo ume of over 850 pages, with about 270 illustrations.

WELLS ON THE EYE—New Edition—Nearly Ready.

A TREATISE ON DISEASES OF THE EYE. By J. Soelberg Wells, late Profess Ophthalmology in King's College Hospital. Third American, from the Third English tion. Thoroughly Revised, with copious Notes and Additions, by Charles S. Bull, M Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with 250 Engravings on Wood and six Colored Plates, together with selections from the test- of Jaeger and Snellen. In one large and very handsome octavo volume of nine hundr

FLINT'S PRACTICE—New Edition—In Press.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE, designed fo use of Students and Practitioners of Medicine. By Austin Flint, M.D., Profess the Principles and Practice of Medicine in Bellevue Med. College, New York. Fifth tion, carefully revised and much improved. In one large and closely-printed octavo ume of about 1100 pages.

FOTHERGILL'S HANDBOOK OF TREATMENT—New Edition—Just Rea

THE PRACTITIONER'S HANDBOOK OF TREATMENT; or, the Principles of Th peutics. By J. Milner Fothergill, M.D. Edinb., M.R.C.P. Lond., Asst. Physic the West London Hospital; Asst. Physician to the City of London Hospital, etc. Se edition, revised and enlarged. In one very neat octavo volume of about seven h pages. Cloth, $4; very handsome half Russia, raised bands, $5 50.

EMMET'S GYNÆCOLOGY—New Edition—Just Ready.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the Use of Studen Practitioners of Medicine. By Thomas Addis Emmet, M.D., Surgeon to the Wo Hospital of the State of New York, etc. Second edition, thoroughly revised. I very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leathe very handsome half Russia, $6 50.

FOSTER'S PHYSIOLOGY—Revised Edition—Just Ready.

A TEXT-BOOK OF PHYSIOLOGY. By Michael Foster, M.D., F.R.S., Prof. of Phys in Cambridge Univ., England. A new American from the third English edition. E with extensive notes and additions, by Edward T. Reichert, M.D., Demonstrator of perimental Therapeutics in Univ. of Penna. In one handsome royal 12mo. volu 1030 pages, with 259 illustrations. Cloth, $1 50; leather, $2 00.

THE SAME. English Student's Edition. Latest issue. In one small 12mo. volume o pages, with 72 illustrations Cloth, 75 cents.

CORNIL & RANVIER'S PATHOLOGICAL HISTOLOGY—Just Ready.

MANUAL OF PATHOLOGICAL HISTOLOGY. By V. Cornil, Prof. in the Faculty of icine of Paris, and L. Ranvier, Prof. in the College of France. Translated, with and additions, by E. O. Shakespeare, M.D., Pathologist and Ophthalmic Surge the Philada. Hospital, etc., and Henry C. Simes, M.D., Demonstrator of Pathol Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 p with over 350 illustrations. Cloth, $5 50; leather, $6 50; very handsome half Russia

THE NATIONAL DISPENSATORY—Second Edition—Now Ready.

THE NATIONAL DISPENSATORY, CONTAINING THE NATURAL HISTORY, CH ISTRY, PHARMACY, ACTIONS AND USES OF MEDICINES, including those r nized in the Pharmacopœias of the United States, Great Britain, and Germany, numerous references to the French Codex. By Alfred Stillé, M.D., LL.D., Prof. Theory and Practice of Medicine and of Clinical Medicine in the Univ. of Penna. John M. Maisch, Ph.D., Prof. of Mat. Medica and Botany in the Phila. Coll. of Phar Secy. to the Am. Pharmaceutical Association. In one very handsome octavo volu 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50, Russia, raised bands and open back, $8 25.

CLINICS.

Clinical Lectures.

ON SEXUAL DEBILITY, SEXUAL EXHAUSTION, AND IMPOTENCE.

A CLINICAL LECTURE DELIVERED AT THE JEFFERSON MEDICAL COLLEGE HOSPITAL.

By SAMUEL W. GROSS A.M., M.D.,

TURER ON VENEREAL AND URINO-GENITAL DISEASES IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA, AND SURGEON TO THE HOSPITAL.

Gentlemen: At my last two clinics I introduced patients with certain eral and local motor, sensory, and secretory neuroses dependent upon ons of the urino-genital apparatus. Of the nervous disorders relating muscular movements remote from the genital organs, you will remember d, eight years of age, with paralytic talipes equinus, and a child of four rs who was suffering from impairment of the power to coördinate the untary movements of the lower extremities. In both of these cases trouble arose from an elongated, contracted, and adherent prepuce. also had under observation a man, twenty-three years of age, who greatly annoyed by vertigo and twitching of the muscles of the legs, ich were traced to excessive sensibility and stricture of the urethra. the sensory neuroses you have seen examples of morbid states of the thra giving rise to pain in the back, shoulders, nucha, head, and in one at the outer side of the tendines Achillis; and I had before you a in whom numbness of the thighs was a prominent symptom.

n addition to these reflex nervous disorders of the system at large, you recall the cases of neuroses of the urino-genital organs themselves ing from various affections of those systems. Among the local neuroies you have witnessed instances of spasm of the urethral muscles, of spasm and paralysis of the sphincter and detrusor muscles of the der. Of the sensory troubles, cases of hyperæsthesia of the urethra, es, and spermatic cord were quite common; while of the secretory oses, which were also combined with motor and sensory phenomena, ve introduced examples of prostatorrhœa, nocturnal pollutions, and spermatorrhœa. In the majority of these cases we found other symptoms, such as impairment of memory, troubled and unrefreshing sleep, a feeling of heaviness on rising, coldness of the hands and feet, poor appetite, constipation, coated tongue, palpitation of the heart, and additional signs of dyspepsia. Prominent among the subjective symptoms were dorsal pain, which was increased by exercise and exposure; muscular weakness of the limbs, so that the patients were exhausted by comparatively slight exercise and exertion; and a feeling of fatigue on getting out of bed. These phenomena, I told you, indicated neurasthenia, nervous exhaustion, or the depressed form of spinal irritation, which, in the absence of post-mortem evidence, is supposed to be due to anæmia of the lumbar division of the cord.

In endeavouring to account for these symptoms I impressed upon you the necessity of exploring carefully the male organs of generation when examination of the cerebro-spinal axis failed to throw light upon them. While phimosis, acquired or congenital contraction of the urinary meatus, balanitis and stricture of the urethra frequently give rise to reflex neuroses, I hav found that they are usually traceable to inflammatory disorders of th prostate, which bear the same relation to nervous affections in the mal that lesions of the uterus do to allied disorders in the opposite sex. Th prostate, with its intercallated acinous glands, and the structures that ar contained within or traverse it, as the urethra, the veru montanum, th sinus pocularis, or prostatic vesicle, or utriculus, which is the homologue of the uterus, and the ejaculatory ducts, are supplied by large nerves de rived from the hypogastric plexus of the sympathetic, the sacral plexus the spinal nerves, and, through the lumbo-sacral trunk, from the lumb plexus. In consequence of the free interchange of fibres between th sympathetic and the cerebro-spinal systems of nerves, it is obvious that th component parts of the genitalia are not only in intimate connection wi one another, but also, through the agency of the cord, with remote par Hence it is that prolonged hyperæmia or inflammation of the prostate an its included structures gives rise not only to essential symptoms, but occ sions various signs in other organs and tissues which are of a reflex o functional nature. If the inflammation becomes chronic, and if the caus that produce it, of which the most common is undue excitement of th sexual function from masturbation, excessive venery, and unsatisfied an prolonged desire, be kept up, exaggerated irritability of the medullary an vaso-motor centres will set in and soon be followed by exhaustion or an mia of the lumbar spinal cord, and the condition known as neurastheni

I shall ask your attention this morning to sexual exhaustion, which i another common and distressing reflex neurosis connected with the mal genital function, although impotence, or inability to perform coitus pro perly, may result from vices in the conformation of the genital organs, o be merely symptomatic of central lesions of the nervous system. Of thi condition arising from inflammatory affections of the reproductive app ratus, to which alone I shall refer, there are several grades which I wi illustrate by typical cases, derived mainly from the out-patients' depart ment.

CASE I.—A teacher, 24 years of age, tells me that he acquired th habit of masturbation when he was fifteen or sixteen years old, and th he kept it up for about three years. During the ensuing two or thr years he had occasional sexual intercourse, but, to use his own languag "for the past twenty-four months I was unable to perform the act, owi to an insufficient erection and a premature discharge. My greatest trouble for five years has been voluptuous dreams; and the nocturnal emissions would sometimes occur for five consecutive nights, causing great mental and physical depression. I find that in toying with or fondling women a discharge oozes from my urethra in quantities sufficient to stain my linen. My memory is impaired; I have lost some flesh; and I am easily fatigued."

You will observe that the external genitalia are normal. On inserting a No. 22 French exploratory bougie, I discover a stricture one-eighth of an inch behind the meatus, and I find that its further passage is attended with great pain, which becomes excessive in the prostatic portion of the urethra. On withdrawing the instrument I find that its shoulder is arrested by another coarctation at five inches and three-quarters, and that it brings away some prostatic discharge.

CASE II.—A mechanic, 26 years of age, states that for the past eighteen months he has had intercourse with one woman three or four times every night, and that he occasionally fulfilled engagements of a similar nature with other females. Latterly he has observed that his powers were growing feeble, and at present his erections are flabby and his ejaculations precipitate. He looks pale; is easily fatigued; and suffers from pain in the back and from frequent and painful micturition.

As in the preceding case, the penis and testes are perfect; but a No. 25 explorer detects a very sensitive urethra and a stricture seated at six inches from the meatus. The neck of the bladder is also extremely irritable.

CASE III.—A weaver, 37 years of age, has been under treatment in the out-patients' department for the past month for hyperæsthesia of the urethra complicated by two strictures, one of which is located at three inches and a half and the other at six inches from the meatus, the latter being narrow and tortuous and only permeable by soft instruments. He has had gonorrhœa three times, the last attack having occurred fourteen years ago; and for the past three years the erections have been growing more and more feeble, until they frequently passed off before intromission, and coitus was always attended by precipitate ejaculation. In addition to his sexual troubles, he complains of numbness along the outer side of the left thigh, almost constant dorsal pain, and a dull, heavy pain in the back of the head, the left side of the neck, and the left shoulder, all of which localities now and then suddenly and temporarily become red and hot. The suffering is aggravated by exercise and continuous work; his sleep is unrefreshing; and he has dyspeptic symptoms.

These three cases represent the most common form of sexual debility, the prominent signs being imperfect or feeble erection and premature ejaculation. Desire, however, is unimpaired, and intercourse is possible, although it is unsatisfactory. In all the exciting cause was chronic hyperæsthesia and inflammation of the prostatic urethra which was produced, respectively, by masturbation, excessive coitus, and gonorrhœa, and was kept up by one or more strictures. One case was complicated by nocturnal emissions, and another by inflammation of the neck of the bladder. In all there were symptoms of neurasthenia and anæmia of the lumbar division of the spinal cord; and as Goltz has shown that this portion of the cord is the centre for the erigent and ejaculatory nerves, we can readily account for impairment of the virile power when its healthy action is depressed or its energy is diminished.

The next patient whom I shall introduce illustrates the second grade or form of sexual exhaustion, which is characterized by entire loss of the power of erection, without, however, abolition of desire. Hence persons affected in this way are not only impotent, but from their inability to practise coitus, they are also sterile.

Case IV.—This man is a mechanic, aged 23 years. At about his sixteenth year, after having been in the habit of masturbating freely for six or seven years, he observed a urethral discharge. He never had sexual intercourse until he was twenty-one; and, after a few months of moderate indulgence, the discharge increased, and the erections became more and more weak until he was finally unable to consummate the act, although the desire remained. He is pale; suffers much from pain in the back, the shoulders and anus, and the left temporo-maxillary articulation; and is easily fatigued.

When he presented himself two weeks ago, examination with a No. 25 explorer, which was attended with great nervous agitation, disclosed intense hyperæsthesia of the entire urethra, and particularly of its prostatic portion, but there was no indication of a stricture. He afterwards rode to his house in the street cars, and about two hours later, after urinating, he was seized with a curious crawling sensation in his arms and legs, lost consciousness, and, when found by his friends, was lying on the floor, and his face was livid. On his next visit, three days subsequently, he was placed upon thirty grains of bromide of potassium with five drops each of juice of belladonna and tincture of gelsemium every eight hours, and directed to take ten grains of quinia one hour before his next visit, which occurred one week ago. At that time a conical steel bougie was passed, and one third of a grain of morphia thrown under his skin.

To-day he reports that the passage of the instrument brought on a slight epileptoid paroxysm, as indicated by clonic spasms of the muscles of the arms and eyelids, and a feeling as if he would become unconscious; and these symptoms were followed by prostration and numbness of both hands. With the view of preventing or mitigating a similar seizure he has taken ten grains of quinia, and he will have a third of a grain of morphia administered hypodermically before he leaves the amphitheatre. You will observe, as soon as the exploratory bougie enters the canal, the tremor and retraction of the testes, and as the bulb reaches the prostatic urethra you see that he shrinks from the excessive pain which it awakens, and that the muscles of the lids, nose, and mouth twitch convulsively. On withdrawing the instrument it is found to be covered with prostatic secretion.

As in the previous cases, the sexual difficulty in this man arises from inflammation and morbid sensibility of the urethra, and more particularly of its prostatic portion. It is moreover interesting from the fact that instrumental contact provokes epileptoid attacks, a complication which is by no means commonly witnessed.

In the third phase of the affection, not only is there complete loss of erectile power, but sexual desire is likewise abolished. Fortunately I have no illustration of this condition. I say fortunately, because the subjects are extremely liable to melancholy and hypochondrism; and although the lesions upon which their impotence depends may be removed, their mind is so seriously affected that a final recovery is almost hopeless.

Finally, there is a fourth class of cases, in which there is desire and complete power over erection and coitus, but the patient is unable to have a seminal discharge, although he may have voluptuous sensations.

This peculiar state, which is known as aspermatism, I include among the reflex neuroses from inflammation and hyperæsthesia of the prostatic portion of the urethra, because I discovered those lesions in the four instances that have come under my observation. Aspermatism may be due to a tight stricture, to absence, obstruction, or deviation of the ejaculatory ducts, either as the result of disease, injury, or a congenital vice, to obliteration of the prostatic vesicle, and to various morbid conditions of the prostate and testis. Of these lesions, however, I have nothing to say, as I distinctly stated at the beginning of this lecture that I would only consider impotence as a temporary neurosis arising from inflammation and undue sensibility of the prostatic urethra.

In the majority of cases, although there is absence of ejaculation on coitus, the patient has nocturnal emissions; but when he is awake neither the venereal act nor masturbation can provoke a seminal discharge. Just exactly what the trouble is, is a mere hypothesis; but I fancy that there is a want of excitability of the reflex ejaculatory centre, or that there is reflex atony of the muscular structure of the seminal passages. However this may be, the next patient affords an admirable illustration of this curious condition complicated by prostatorrhœa.

CASE V.—A teacher, 22 years of age, had gonorrhœa five years ago, which degenerated into a gleet. For the past three years he has had a more or less colourless discharge, particularly after erections and straining at stool. During the past eighteen months he has been unable to have an ejaculation during coitus, although he prolongs the act until fatigue requires him to cease. Now and then he has a nocturnal emission, attended with diminished sensation, under the influence of a voluptuous dream; and erections are provoked by slight causes. He is continually morbid about his condition, so that he can scarcely attend to his daily duties, being unable to fix his thoughts for any length of time upon any subject except his sexual trouble. He has pain in his back, loss of appetite, and palpitation of the heart.

Exploration with a No. 25 bulbous explorer discovers a very sensitive prostatic urethra, a linear stricture at six inches from the meatus, and a considerable prostatic discharge.

In all of the cases that I have introduced, hyperæsthesia, particularly of the prostatic urethra, which was maintained in four out of the five by one or more strictures, and induced by masturbation, sexual excesses, and gonorrhœa, was the prominent symptom. Hence, I feel warranted in stating that undue sensibility and excitement of the prostatic portion of the canal and of the ducts which open into it, are the most common and important causes of the spinal reflexes which make themselves known by the various grades of sexual exhaustion or impotence, and other signs of the depressed form of spinal irritation.

Of the relative frequency of the four varieties of sexual troubles of which I have spoken, an examination of 97 cases that have come under my personal observation discloses that 87 were examples of feeble erection and premature ejaculation; 4 were instances of loss of power of erection, with retention of desire; 2 were examples of loss of both power and desire, and both were hypochondriacs; while 4 came under the class of aspermatism.

The etiological factors were, gonorrhœa in 30, masturbation in 66, and excessive coitus in 1. Just how far prolonged and unsatisfied passion, produced by toying with females, is to be considered an exciting cause of the affection I am unable to say, since I find that young men addicted to this habit are very liable to relieve themselves by onanism.

With regard to masturbators I have made some notes that are interesting and practically useful. Thus I find that one in every three has a elongated prepuce ; one in every five has an inflamed meatus ; one in every two and a half has a very sensitive urethra; that the same proportion suffers from a gleety discharge; and that one in ten has a small penis. As I have pointed out in a paper read before the Philadelphia County Medical Society, and published in the *Medical and Surgical Reporter* for May 3, 1877, and in a paper which appeared in the *Transactions of the American Medical Association* for 1877, protracted masturbation is just as sure to result in urethritis and the formation of stricture as is a chronic clap. Of the 66 masturbations only 3, and one forms the subject of Case IV., were free from stricture, so that that lesion should always be looked for i this class of patients. In about five-sixths of the cases there is only o coarctation, while in the remainder two or more strictures will be foun In one-sixth of the entire number the contraction is seated within the fir inch of the urethra.

In the treatment of disorders of the genital function arising from preternatural sensibility of the prostatic urethra your first care should be t make a thorough examination of the generative and associated organs wi the view of getting rid of the causes which produce and maintain the If the patient has a redundant prepuce, it should be removed ; if the me tus be contracted, it should be enlarged; while herpes of the prepuce a glans, or balanitis should be treated in the usual way. All of th lesions are capable of setting up hyperæsthesia of the prostatic portion the urethra, or even of exciting reflex impotence without the interventi of prostatic trouble, and their relief is quite sufficient in mild cases to r store virility. The same statement is true of certain diseases of the rec tum, so that the lower bowel should receive due attention.

In the great majority of cases you will find, as you have learned fro the patients that have been brought before you, that the treatment is to b directed to overcoming the hyperæsthetic prostatic urethra, which is us ally complicated by stricture of the spongy portion of the canal. Hen your remedies, whether these be local or general, must be of a sedati nature; and your patient at the outset should be impressed with the i portance of avoiding all sources of sexual excitement, such as coitus, ma turbation, dalliance with women, and lascivious thoughts and literatur Of general remedies, the aphrodisiacs, as cantharides, phosphorus, a damiana, are harmful; while anaphrodisiacs are always indicated. Of th latter, an extended experience has convinced me that bromide of pota sium is by far the best, as it not only blunts the venereal appetite, but al corrects the acidity of the urine, and exerts an anæsthetic influence o the urethral mucous membrane. I am in the habit of administering thirty grains every eight hours, unless I find it makes the patient too drowsy during the day, when I order a drachm to be taken at bedtime. If sig of bromism appear, I reduce the dose ; or if the remedy is badly borne I usually substitute ten drops of tincture of belladonna, and five drops each of tincture of gelsemium and Fowler's solution, three times a day, which is an admirable combination. The preparations of belladonna are particularly appropriate when the case is complicated by nocturnal emissions, and may be given in the form of the fluid extract, tincture, or juice, or of atropia administered hypodermically or by the mouth. When the patient is anæmic, he should also take tonics, of which a combination of quinia, tincture of the chloride of iron, and tincture of nux vomica is one of the most suitable.

In addition to sedatives and tonics the bowels should be kept in a soluble condition, particular attention being paid to the rectum. For this purpose, ordinary hydrant water may be thrown into the lower bowel every morning, as it has the additional advantage of soothing the irritated prostatic urethra. If cool water enemata do not answer the purpose, and there is atony of the muscular coat of the intestines, a pill composed of two grains of the compound extract of colocynth, half a grain of the extract of nux vomica, and the tenth of a grain of extract of belladonna may be administered on going to bed; or, if it be deemed desirable to act on the liver, a wineglassful of Hunyadi water, or two or three drachms of equal parts of Epsom and Rochelle salt, may be ordered every morning. Any especial dyspeptic symptoms are to be met by appropriate remedies.

The diet should be nutritious and digestible, but unstimulating. The patient must eschew coffee, malt and alcoholic liquors; and his supper should be light. He should sleep on a hard mattress, use only the lightest coverings, and empty his bladder thoroughly on retiring, and early in the morning, if an erection indicates fulness of that viscus. He is to be warned against horseback exercise and driving over rough streets and roads, and all other forms of amusement which tend to produce hyperæmia of the genitalia, as well as against mental and bodily fatigue if the signs of neurasthenia be marked. Benefit will accrue from moderately cool lotions to the dorso-lumbar region, in the form of irrigation, the douche, or the wet sponge; and syringing cool water against the perineum will be found to be of great service when prostatic discharges or pain on exercise indicate that that organ and its included urethra are too excitable.

Of the local measures to overcome chronic congestion, inflammation, and hyperæsthesia of the veru montanum, the prostatic urethra, the ejaculatory and prostatic ducts, not one is so universally applicable as the passage of the conical steel bougie. The size of the instrument is to be gauged by that of the meatus if it be normal, or by that of the stricture if one be present, and its circumference should be gradually increased up to the full capacity of the urethra, as indicated by the urethrometer. To effect this, however, the meatus will have to be enlarged as a preliminary measure, or you may use my urethral dilator which dispenses with that operation. At first the bougie should be at once withdrawn, and the intervals between the insertion should be forty-eight hours. With the decrease of the sensibility it should be retained longer, and the intervals of introduction be shortened. If the stricture be irritable or resilient it should be subjected to internal urethrotomy, as no progress can be made unless the contraction be a simple one.

As an illustration of the readiness with which cases of sexual debility improve under simple and properly directed measures, I show you a patient who was before you just four weeks ago.

CASE VI.—On the 8th of April, a mechanic, aged 23 years, gave us the following history. He complained of a gleety discharge, which kept the lips of the meatus glued together, and had existed for two years and a half; of a discharge of prostatic fluid at stool; and of nocturnal seminal emissions, which were often as frequent as every night during a single week, and now and then occurred to the number of three in a night. The erections were feeble, and ejaculation was premature. The bowels were costive, but he had no signs of spinal exhaustion. Examination with a No. 17 explorer disclosed a stricture one-eighth of an inch behind a contracted meatus, and a highly sensitive urethra, especially in its membranous and prostatic divisions. On withdrawing the instrument a few drops of prostatic fluid came away. I laid open the meatus along with the stricture, and directed the pill of colocynth, nux vomica, and belladonna at bedtime, and thirty grains of bromide of potassium every eight hours. The incision was prevented from closing by the passage of a No. 30 conical steel bougie, which was passed through the entire urethra every other day for three weeks, and daily for the past week. To-day, May 6th, the hyperæsthesia has almost entirely disappeared; the gleet has ceased; there is merely a slight prostatic discharge if the bowels are allowed to become constipated, but he has not noticed it for several days; there were nocturnal emissions on the nights of April 17 and 18, and the erections are improving in vigor. The treatment will be continued, and a cure may be looked for in another month.

All cases do not respond so quickly to treatment as this one. Should the tenderness of the urethra prove refractory, you may resort to compression combined with the local application of cold with the cooling sound, or psychrophor of Winternitz, which is nothing more than a double current catheter closed at its beak. By means of these tubes a stream of water of a temperature of about 59° should be passed through the instrument for ten minutes. In many instances you will find that the inflammation and morbid sensibility are finally reduced to a small, and probably granular, patch, which will demand astringent applications. Of these I prefer a twenty-grain solution of nitrate of silver, carried to the tender spot in the way you have so often seen me do, and which I told you I learned from M. Felix Guyon, the successor of Civiale at the Hôpital Necker, at Paris. I charge the small syringe with the solution, attach to its nozzle a hollow bulbous bougie or explorer, and press upon the piston until a drop of the fluid appears at the hole in the apex of the bulb. Wiping this off, I oil the bougie, carry it down until the bulb defines the inflamed patch, withdraw it slightly, when, with my finger on the piston, I deposit a few drops of the liquid in the urethra. The bladder should be emptied before making the application, and the patient should be kept in bed for some hours subsequently, and use demulcent drinks. With these precautions the only inconvenience to which he will be subjected will be some scalding during the next act of micturition. The application need not be made oftener than once a week. In the absence of this contrivance, you may employ the catheter-syringe, the instrument provided with a concealed sponge, or the porte-caustique of Professor Gross, the cup of which is charged with the nitrate rubbed up with stramonium ointment. When the affection proves more obstinate, as it is liable to do when it is chronic, and complicated by prostatorrhœa in mature subjects, flying blisters, made by pencilling cantharidal collodion on each side of the perineal raphé, are of the utmost service.

Up to this point you will observe that the treatment, both general and local, has been addressed to relieving the inflammation and hyperæsthesia of the deep urethra. When this has been accomplished, nothing more, as a rule, is required; but cases occur in which after the local lesions have been cured, the erections are still not sufficiently vigorous and the ejaculations are premature Our object now is to restore the sexual powers y the internal exhibition of iron, quinia, strychnia, phosphorus, ergot, nd tincture of cantharides, alone or variously combined; by cool hip-aths and cool applications to the dorso-lumbar region; and by electricity. he anode of a battery is placed over the lumbar spine, and the cathode arried over the spermatic cord, the testes, perineum, and back of the penis. he sittings at first should not exceed five minutes, or be repeated oftener an every forty-eight hours. The current, moreover, should be feeble, d not excite pain even when its strength is increased. When there is ony and relaxation of the ducts, as shown by prostatic and seminal disarges after the hyperæsthesia has disappeared, a negative urethral electode may be passed down to the prostatic urethra, or one may lie in that cality while the other is inserted into the rectum. I must caution you, wever, to be careful in the use of the urethral rheophore, as I saw not ng ago in consultation with my friend, Dr. Asch, of New York, a gentlean who had lost his right testicle from suppuration through its employent while the urethra was still irritable. In addition to these measures change of air, travel, exercise, amusement, and sea-bathing will do much tone up the system.

The end having been accomplished, it remains to put your patient on guard against sexual excesses. Unless he practises moderation, he is ble to a relapse; and if he is single you should advise him to marry. hen sexual exhaustion arises from central nervous lesions, he should main single; but when it is due to prostatic trouble, and there is no pochondrism, you are perfectly safe and right in recommending matriony.

In the management of these disorders, I have not had aspermatism in ew. Although I have seen four cases, I have not been able to conduct treatment in a single one; but as I fancy that this condition, when it combined with inflammation and morbid sensibility of the deep urethra, pends upon atony of the seminal vesicles, I have no reason to doubt that e course which I have outlined will prove effective.

N THE RADICAL CURE OF VARICOCELE BY THE GALVANIC ÉCRASEUR.

A Clinical Lecture delivered at the Westminster Hospital, July 3d, 1880.

BY A. PEARCE GOULD, M.S., F.R.C.S.
Assistant-Surgeon to the Hospital, and Lecturer on Anatomy to the Medical School.

GENTLEMEN: Although there are very many cases of varicocele in which no eatment, or only palliative measures, are required, you will meet with others which it will be your duty to undertake the permanent or radical cure of the arix. These cases are as follows: 1. Where the testicle is atrophying. 2. Where e varicocele is double, especially if an examination of the semen shows an bsence of spermatozoa, or the patient, being married, is sterile. 3. Where the pposite testicle is lost or useless from tumour, orchitis, epididymitis, or injury. 4. Where the varix is large and increasing, in spite of palliative treatment. 5. Where the varix causes much pain, or interferes with proper exercise and necesary work. 6. Where it is the occasion of marked mental depression. 7. Where the varicocele prevents acceptance for either of the Government services.

There are many plans for securing the radical cure of varicocele, includi castration, excision of the veins, the actual cautery, forcipressure, and ligatu The ligature is the method most commonly adopted, and has been variou modified by Ricord, Vidal, Erichsen, Wood, and H. Lee. (These methods treatment were then described.)

Of the efficacy of these treatments there can be no doubt, but unfortunate they have two drawbacks—the pain attending them, and a certain amount danger. For a long time surgeons avoided as far as possible any interferen with veins, and although veins are now ligatured almost as freely as arteri there is no doubt that diffuse thrombosis, embolism, and septic poisoning a more liable to follow injuries of veins than of arteries. This being so, it is plain the surgeon's duty to avoid in every possible way any irritation or disturbance an injured vein, and it is because this principle is not sufficiently carried out th the usual modes of treating varicocele have been attended with serious and ev disastrous results. The daily twist of Vidal's pin, and constant traction of Woo spring, are not only painful, but opposed to the great principle that dema perfect rest to all inflamed and injured tissues, and veins in particular, while, Lee's operation, the presence of two harelip-pins transfixing the scrotum is to set up œdema and inflammation, and their removal is not without risk of em lism. That these are no imaginary fears is evident from the published results these and analogous treatments. Gant says that the results of the operations "variable," and include diffuse inflammation and sloughing of the scrotum, s puration of the testicle, phlebitis, pyæmia, and death; Erichsen records t deaths from the twisted suture; Gross had one death after ligature; Sir E. Ho had one nearly fatal case; Escallier mentions two fatal cases of phlebitis, Curling speaks of three cases of serious results, two of which were fatal. So years ago the censor of one of the chief London hospitals died from pyæmia a Lee's operation. This list by no means includes all the accidents of these tre ments—it makes no mention of the pain suffered, or of the inflammatory œde and suppuration of the scrotum.

It was with the hope of avoiding these complications that I was led, now mo than two years ago, to try the plan of subcutaneous division of the veins by mea of a platinum wire heated to a red heat by electricity. The procedure is, as y have seen, very simple. First, feel for the vas deferens, and grasp the veins front of it, and nip in the scrotum with the left thumb and forefinger; trans the scrotum at this spot between the duct and the veins with a narrow bistour and pass a needle armed with a platinum wire in the track of the knife; th return the needle through the same apertures, but this time in front of the vei between them and the skin. Of course, if the vas happen to be in front of th veins, as was the case in that of W. C., shown to-day, you modify the pr cedure a little. In this way you have the veins in a loop of the wire. It is bette to make a puncture with a knife rather than merely to transfix with the needle, for the veins are looped up cleaner, there is not the same liability to include portion of the skin in the noose as in the latter plan. Then attach the ends o the wire to the écraseur, and connect with the battery, using sufficient cells t cause a faint hissing noise; one cell of Grove's battery, or at most two, is sufficient. This step must be done deliberately; I have taken as long as five or six minutes over it. To protect the skin from burning, let some cold water trickle over it while the wire is burning its way through the veins. The after-treatment consists in perfect rest in bed for a few days, with the scrotum supported on a broad strip of strapping fixed across the front of the thighs. I have three times operated without anæsthesia, but the pain may be severe, and I prefer to have the patient under the influence of ether. After recovery from the anæsthesia there is an entire absence of pain, and this perfect freedom from spontaneous pain continues uninterrupted throughout the convalescence. A few hours after the operation the knobby feel of the varix is replaced by a soft even swelling, which lessens and hardens, and at the end of forty-eight hours is usually to be felt as a hard lump, about the size of a big marble. This is tender on pressure. By the end of a week it has lost its tenderness, and has shrunk to three-quarters its original size. The veins below can still be felt full, but not compressible, the blood in them has by that time coagulated, and they become smaller and firmer, until ultimately a small pea-like induration in front of the vas is all that is left, and even this may disappear, and no trace of the varix or operation be left, as in W. S.

I have employed this method eight times, each time the varix has been cured, the symptoms complained of relieved, and no mischief to the testicle has followed. These eight cases have shown me that there are three things to be carefully avoided. The first is hurry in the section of the veins; twice a few drops of blood have followed the escape of the wire, but only so little as to require nothing more than lint or cotton-wool to be placed over the wound; in neither instance was there any hæmatocele. The second is to operate well above the tunica vaginalis; in one of my cases acute hydrocele was lighted up, it quickly subsided under belladonna fomentations. The third is burning of the skin, leading to a small slough; although there is nothing of serious moment in this slough, it is of course best to avoid it, and if the skin is incised and kept cold and the loop of wire not brought too small it can generally be saved.

I can recommend you to practise this operation, first, because of its entire painlessness after the few moments of its actual performance, and, secondly, because it fulfils the physiological indications better than any other I know of. My cases at present are too few to prove by statistics that it is less dangerous to life than those operations I have mentioned, but they are sufficient to show that the operation is simple, effectual, and introduces no new danger, while it is obviously free from the sources of irritation common to other methods.

The section of the veins is completed at once; there is no foreign body liable to set up inflammation left in contact with the healing veins, which are allowed to remain at perfect rest, while their seared ends are becoming permanently closed. As you are aware, the closure of an open vessel by the hot wire or iron is usually considered a particularly safe plan. There is also no interference with the skin of the scrotum, as in Lee's operation; no compression of the scrotal vessels, no œdema.

The only other method that I should at all recommend to you is the use of the catgut ligature applied to the veins subcutaneously. I have had no experience in it, but it has been done with success. I think the heated wire is preferable, because the catgut ligature is rather uncertain in its action; it may soften very rapidly and then fail to occlude the vessels, or it may not soften at all and cut its way through the veins like an ordinary hempen or silk thread, or remain and subsequently light up inflammation. These accidents are only occasional, but we should none the less be on our guard against them, and give the preference to a plan of treatment which is free from them. In none of my eight cases has any slough separated from the veins; the eschar formed has been absorbed by the living tissues. I show you to-day four cases at varying periods after the operation illustrating their progress.

1. W. J., aged seventeen, a large left varicocele, which he had noticed for "several years," left testicle smaller than right, complained of dragging pains in scrotum and up to left loin. Operation, June 21, 1879; left hospital June 28th. A firm induration the size of a marble felt; not tender; veins below plugged.

2. F. L., aged twenty-four, single, injured left testicle five years ago; fir noticed varicocele three years ago, after an attack of clap, since then the pai and swelling had steadily increased in spite of wearing a suspender. No consti-pation; external piles for two years. Operation May 28th; left hospital Jun 8th. The induration is very hard, the size of a horse bean; veins below are fir and shrinking.

3. W. C., aged thirty, single, very large left varicocele, noticed suddenly i June, 1879, while bathing. Pain in scrotum and groin had increased of late; testicle smaller than right. Operation May 1st; left hospital May 7th; delaye on account of a slough of skin. Induration now small; veins below cannot b felt; testicle has regained its former size and is a little larger than right.

4. W. S., twenty-one, a small varicocele noticed some years; scrotum not lax considerable pain; frequent seminal emissions and mental depression. Operatio Sept. 29th; left hospital Oct. 9th. No trace of dilated veins or of the seat o the operation to be felt. All symptoms relieved.—*Lancet*, July 17, 1880.

Hospital Notes.

A Case in which One-third of the Cranium was Denuded by an Injury: recovery in fifteen days.

Eliza H——, a machinist, aged twenty-three years, was admitted into th Great Northern Hospital, under the care of Mr. Spencer Watson, on Fe 5th, at 8 P. M., having thrown herself from a second-floor window (a height about thirty feet) to escape from a fire. She seemed to have lost consciousne in the act of falling, but thought that she fell upon the body of another girl wh had also precipitated herself from the same window. The whole of the post rior third of the scalp, from a line extending from the mastoid process on on side to the corresponding part on the other across the top of the head, was de tached from the skull and hanging loose on the nape of the neck. It was reap plied, and the edges of the wound brought together by hare-lip pins and strap ping, and carbolized oil lint applied as a dressing; the hair of the head was pre viously cut off close to the scalp. She passed a quiet night, the temperatur next morning being 99° and the pulse 96.

On Feb. 10th she was restless during the night, and had great pain in the head Temperature 102.6°; pulse 120. The dressings were removed and the hare-li pins taken out. The whole of the scalp felt "boggy," but there was no distinct fluctuation. The face was puffed and œdematous. Charcoal and linseed poul tices were applied, perchloride of iron was given in ten minim doses, and a calome purge was administered. Next day the temperature was 98.6°, and the girl fel altogether better.

After this date the recovery was only interrupted by a small collection of pu under the scalp at one limited spot; it discharged itself, however, through the original wound, and by Feb. 20th the latter had almost healed. On the 6th of March the wound had completely healed.

Remarks.—The rapid recovery from such an extensive denudation of the cranium is the most interesting feature of this case. The young woman's very good general health must be taken into account, as giving her the best chance of recovery, but the antiseptic dressings must be credited with some part of the good result, and the absence of serious complications.—*Lancet*, June 26, 1880.

MONTHLY ABSTRACT.

Anatomy and Physiology.

Origin of Blood-corpuscles.

A memoir by POUCHET which has recently appeared in the *Revue Scientifique* (and which has been translated in the current number of the *Quarterly Journal of Microscopical Science*), discusses the interesting subject of the mode of production of the red blood-corpuscles. It is not a little remarkable that the origin of the formed elements of the blood should still continue to be a matter of hypothesis, and that physiology is incapable of replying to the question, How after large losses of blood is its restoration effected? The present generation of practitioners are hardly aware of the quantity of blood that was taken from patients in acute disease by the physicians and surgeons of the past age. If works written in the early part of the present century are referred to, some surprising facts of this nature will be found. At the time when Sir W. Lawrence's treatise on the Venereal Diseases of the Eye was published—that is, in 1830—bleeding was the approved method of treating gonorrhœal ophthalmia; and amongst other cases he records in that work there is one of a pugilist, who was no doubt an athletic, freely living man, but who, having contracted gonorrhœal ophthalmia, was admitted into St. Bartholomew's Hospital, and from whom the surprising quantity of one hundred and fifty-two ounces, or nearly eight pints, reckoning twenty ounces to the pint, were abstracted by venesection, besides the application of thirty-two leeches, in the short space of one week. Nor was this a solitary case, for several others are recorded in which nearly equal amounts were taken. It is worth noting that the pugilist recovered with perfect vision. In the case of women, again, enormous losses of blood are often sustained in menorrhagia, which are yet quickly restored under favourable circumstances. Rindfleisch has made an estimate of the rapidity with which the reproduction of new corpuscles must take place in ordinary intermenstrual periods, and calculates that half a centigramme of blood is produced every minute, which means that about one hundred and seventy-five millions of red blood-corpuscles are produced every minute. When thus reduced to figures, it seems extraordinary that no answer can be given to the questions how and where this enormous proliferation is effected.

Is the process of renewal performed in some obscure organ whose function has been overlooked—the suprarenal capsules or thymus or thyroid gland, for example,—or is it that the corpuscles, similar as they may all appear to our methods of investigation, are derived from many different sources, each set having its own special and definite functions, and differing in structure, purpose, and destination from all the rest? The results of modern physiological research seem to point in the latter direction. Not many years ago the corpuscles were believed to be exclusively derived from the chyle, and Hewson's observations, to which Mr. Gulliver did good service in calling attention, were essentially in favour of the mesenteric glands being the bed for the production of the lymph corpuscles, the nuclei of which acquired colour and became the red corpuscles. More recently, however, the claims of many other parts of the body to be hæmatopoietic organs have been with more or less probability advanced, and the share of the spleen, the liver, the muscles, the cancellous tissue of the bones, and the peritoneum, in the process of blood formation, has been urged by different experimenters. Objections may, however, be raised to nearly every hypothesis that attributes the origin of the hæmatids to a single source. Even in the case of the lymphatic glands it may fairly be urged that they cannot be exclusively concerned in the generation of the red corpuscles, since such glands are wholly absent in fishes; and the same objection may be taken to the view of Neumann and Bizzozero in favour of the cancellous tissue of the bones. And granting even that they are formed here, by what means do they traverse the walls of the capillaries, and how are they impelled into the current of the circulation? The fact that the spleen is absent in some animals, as the lamprey, and may be removed even in the higher animals and man without rendering them anæmic, disposes of the idea that it does more than aid in the genesis of blood-corpuscles, and, as Pouchet remarks, little weight can be attached to the statements that a new function can be vicariously performed by other organs of a totally different structure.

In regard to the derivation of hæmatids from the lymphoid patches of the mesentery, these regions can evidently play but a small part in the production of new corpuscles. Ranvier has indeed observed hæmatids originating in the midst of vessel-forming tissue. But if this view be correct, the repair of lost blood would be necessarily associated with the production of new capillaries, which has not been demonstrated. The view which is held by M. Pouchet himself, that the real origin of the blood-corpuscles is to be looked for in the hæmatoblasts or minuter form of globules, has been described by Hayem, and long before him by Donné, under the name of globulins. These bodies probably originate in the blood plasma, being primarily formed of albumen, to which subsequently the crystalline substance hæmoglobin is added, causing a great increase in the volume of the globulets. In the blood of animals undergoing repair after large hemorrhages, an extraordinary number of hæmatoblasts or globulets may be observed. These rapidly enlarge in all directions, lose their granular aspect and become hyaline, and finally assume the discoid form and the yellowish tint of the full-formed corpuscle. The hæmatids are on this view neither cells nor the descendants of cells, but may, like Topsy, be said to have simply "growed." It would seem that the generation of the red corpuscles is still a dark corner in physiology, and some further observations are still requisite.—*Lancet*, July 31, 1880.

The Presence of Bile in the Lymph and Blood when diverted from its natural channels of Elimination.

FLEICHL was the first to upset the opinion generally accepted up to his time—that whenever any obstruction whatsoever in the bile duct prevented the elimination of the bile by its proper channels, it immediately made its way into the blood in the substance of the liver itself. After ligature of the bile duct, he found the biliary acids to be present in the thoracic duct before he could detect them in the blood; hence he inferred that the bile made its way into the blood, not directly, but through the lymphatic system. KUFFERATH has verified and extended these views. First he repeated Fleichl's experiments. In eight dogs he tied the bile duct and collected the lymph as it flowed from the thoracic duct. In each case he found the biliary acids present. In two cases only were these acids found in the blood, and in these a post-mortem examination showed that a bifurcating branch of the thoracic duct had escaped ligature. In his second set of experiments, he tied both the biliary duct and the thoracic duct. Three hours afterwards he analyzed the blood. In three out of four cases there was no trace of the hepatic secretion in the blood. In the fourth case, where such was detected, the autopsy showed a second thoracic duct which was unligatured. Hence, e concluded that as there are no biliary acids in the blood three hours after the imultaneous ligature of the bile and thoracic ducts, therefore the bile enters into e blood *exclusively* through the lymphatic vessels. The lymphatics in the liver re stained yellow, so that it is not the biliary acids alone, but the bile itself, hich takes this course.—*Dublin Med. Journal*, July, 1880, from *Journ. de éd., de Chir., et de Pharm. de Bruxelle*, Juillet, 1879.

Indican in Health and Disease.

Dr. H. N. Heineman, Assistant in the Laboratory of the Alumni Associa- n of the College of Physicians and Surgeons, New York, contributes to the *rchives of Medicine*, August, 1880, an interesting paper on this subject, of hich the following are his conclusions:—

Indican is only exceptionally absent in health. It may vary in quantity in the althy individual, generally being small in amount, but occasionally as marked in disease.

Certain diseased conditions tend to produce a decided increase.

The most marked increase is obtained in those diseases which affect the ali- ntary canal, and more especially the small intestines, whether they be local or neral diseases with local lesion. Among these are dyspepsia, gastro-duodenitis, ronic constipation, intussusception, diarrhœa, peritonitis, cholera, lead poison- g, and typhoid fever.

In diseases causing inanition, as phthisis and other prolonged suppurative dis- ses, as caries and necrosis, marked increase is found.

Among the diseases producing altered blood states, some, such as malaria, philis, rheumatism and alcoholism, progressive anæmia and chlorosis, although *ways* causing the most profound blood-changes, *do not always* effect a decided rease. This is a singular exception, to which Senator has called attention, t the investigations are not yet sufficiently numerous to draw conclusions.

Certain nervous disorders, as insanity, epilepsy, Addison's disease, progressive scular atrophy, and paraplegia, cause marked increase.

Disordered function of the kidneys, as in chronic Bright's disease, causes rked increase.

Internal malignant tumors, as carcinomata and sarcomata, cause increase most rkedly and constantly of all.

The explanation of the cause of the increase in various diseases is not as yet equate to satisfy all cases.

On a Filaria reported to have come from a Man.

Prof. Joseph Leidy describes (*Proceedings of Academy of Natural Sciences f Philadelphia*, March 2, 1880) a large thread-worm, which had been submitted his examination by Dr. J. J. Woodward, U. S. A. It was recently presented the Army Medical Museum, at Washington, by Dr. C. L. Garnett, of Buffalo, tnam Co., West Virginia. Accompanying the specimen is the copy of a let- r from Dr. Garnett to Dr. Woodward, from which the following is an abstract: 'During the winter of 1876 a man, a common labourer, aged about fifty, pre- ented himself to me for treatment, having a gleety discharge from the urethra, ith a burning sensation during and after micturition. Previously he had been reated for gonorrhœa, and I prescribed accordingly. The patient not improving, pplied to other practitioners. In April, 1878, he came to me with a round, vid-red worm, twenty-six inches in length (the specimen you now possess) which was alive and very active in its movements, instantly coiling up like a watch-spring on being touched. Having no work on helminthology for reference, the only description I found which appeared to answer to the worm was that *Strongylus gigas*, in Niemeyer, vol. ii. p. 47. The patient is an illiterate ma with no motive for deception. He informed me that he discovered the wo protruding from his penis and drew it out without pain or difficulty. He was much agitation and alarm about the occurrence, fearing, as he said, that "the might be more behind that one." For a few days previous to its passage, urine was of a milky hue and some time subsequently of a yellow cast and slight tinged with blood and mingled with mucus. The man is truthful, and no dou exists in my mind or in the minds of his neighbours as to the correctness of statements. I regret exceedingly that I did not appreciate the scientific inter of the subject, and send you the specimen in a fresh state, but the busy routi of a country practitioner's life leaves no time for the study of other than subje of practical value in one's every-day experience."

Fig. 1.

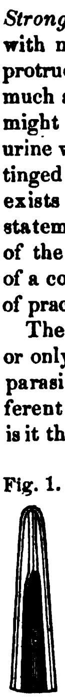

Fig. 2.

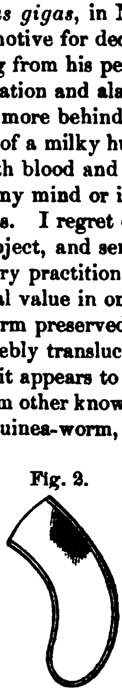

Fig. 1.—Cephalic extremity.

Fig. 2.—Caudal extremity; the diagonal marking indicates the crossing of the fibres seen in the integument. Five diameters.

The worm preserved in alcohol is much coiled, of a clay colour, and opaq or only feebly translucent, but more so at the head end. If it is really a hu parasite, it appears to differ from all those heretofore described, and also seems ferent from other known parasites. It certainly is neither *Eustrongylus gigas*, is it the Guinea-worm, *Filaria medinensis*, though nearly related to this. Its ch acters are as follows: Body long, restiform, nearly u formly cylindrical, smooth, shining, elastic, tough, wi out evident annulation other than transverse wrinkli with the anterior extremity evenly tapering in the conti uous head, the end of which is rounded and smooth without appendages of any kind; the posterior extre not tapering, with the caudal end incurved, blun rounded, without appendages, and imperforate or wi out evident anal or genital aperture. Mouth a termi pore without lips, papillæ, or armature of any ki Pharynx cylindrical, and opening into a straight cy drical intestine, apparently ending in a blind pou Generative organs unobserved. Length of worm, inches; greatest thickness, 1.5 mm. Width of he just behind the rounded extremity, 0.375 mm.; oppos the commencement of the intestine, 0.625 mm.; at th middle, 1.5 mm.; at the incurved caudal extremity, 1.5 mm. Length of œs phagus, 1.125.

The worm, of exceedingly simple character, is clearly neither a *Gordius* nor *Mermis*, and, though apparently more nearly allied to *Filaria*, a more intima knowledge of its structure may prove it to be different. For the present it wa proposed to distinguish it with the name of FILARIA RESTIFORMIS.

Materia Medica and Therapeutics.

Recent Investigations on the Action of Drugs.

An interesting contribution to the facts relating to the antagonism between the actions of drugs has been supplied by PANTELEJEFF with regard to two drugs in common use—quinine and atropine. The salts employed were the chloride of quinine and the sulphate of atropine, and the experiments were made upon dogs, rabbits, and frogs. An injection of quinine beneath the skin of a frog in summer arrests the heart in diastole; but a subsequent subcutaneous njection of atropine causes it at once to resume its pulsation. The appearance f the heart, when its action is arrested by quinine, is as if the blood-pressure on eart was greater than the cardiac walls could contract upon. If atropine was njected first, so as to cause an acceleration, this was arrested by the quinine. Vith winter frogs the effect of the quinine was more frequently to cause a radual retardation in the action of the heart, which was only arrested, after a ime, with loss of reflex action, and death. The injection of atropine did not revent this, but retarded the heart still more. Microscopic examination of the essels of the web of the foot showed that the quinine caused a narrowing of the mall arteries to one-half of their previous calibre, while atropine dilated the essels. In rabbits it was found that when the heart's action was arrested by uinine, atropine caused it again to beat, and the auricles began to contract efore the ventricles. In both dogs and rabbits the blood-pressure in the carotid se after the injection of quinine, when the pulse was rendered less frequent. t was found that immediately after the injection the blood-pressure suddenly alls, but after a few seconds it rises to a higher degree than before the injection. n small doses the pulse is often accelerated during the increased pressure, but ith large doses the pulse is retarded from the beginning. If repeated injections re made, every injection causes first a sudden fall of pressure, with retardation f the pulse; then the pressure rises, to fall again after a new injection. This itial fall in the blood-pressure is probably due to a sudden contraction of the ssels of the lungs, hindering the passage of the blood into the left ventricle nd the aorta. The cardiac contractions become at the same time less frequent, ut stronger. The arteries of the aortic system then contract, and cause an crease in the blood-pressure, and at the same time an acceleration of the pulse. arge doses have a direct influence on the heart, so that, later, the cardiac action comes retarded, and the blood-pressure falls. The pneumogastrics remain ex- able by electricity, but their division exercises no marked influence upon the lse, especially when the respiration is retarded by the action of quinine. Sub- quent injection of atropine accelerates the pulse, even when the pneumogastrics ve been divided. In only one observation upon dogs was an arrest of the heart y quinine prevented by atropine. The increase of pressure caused by quinine as disturbed and retarded by the preceding injection of atropine. Direct appli- tion to the heart of frogs showed that not only can quinine arrest the action of e heart, but that it can also, under certain circumstances, act as a stimulant to xcite it to action, and the effect depends upon the condition in which it is.

The acute effects produced by large doses of atropine have often been studied, ut the symptoms which are produced by such doses as are toxic only when long ntinued have been little investigated. They have, however, lately occupied e attention of Dr. von Anrep in the physiological laboratory of Würzburg. f a dose of one to three milligrammes is administered to a dog by hypodermic njection, the slight symptoms which it causes—mydriasis, etc.—soon pass away. f the injection, however, is repeated, the effects gradually become less intense. After the fifth injection the slight modifications of the cutaneous sensibility and he slight muscular tremors which are caused by the first doses cease to occur, he slight acceleration of the action of the heart is less marked, and the animal maintains its usual health in spite of the continued doses. Chronic poisoning with larger doses gives more persistent results. A single dose of one-twentieth of a gramme causes symptoms of acute poisoning—muscular spasm, vomiting, thirst, and loss of appetite, transient acceleration of the pulse, extreme dilatation of the pupil, quickened respiration, and a slight elevation of temperature. If this dose is repeated on six or ten successive days the symptoms become slighter after each injection, with the exception of the dilatation of the pupil, the acceleration of the action of the heart, and the diminution in the saliva. There is no trace of muscular spasm or tremor. After a long time the heart becomes weakened, its contractions are less frequent, being only one-half of the normal, and the effect of each new dose is to cause only a slight acceleration. From these experiments it appears that a remarkable tolerance is established to the alkaloid, even in considerable doses, so that after a time the animals are unaffected by doses which would have been fatal at the outset of the experiments; but this tolerance is least in the case of those organs and structures which are normally the most impressionable—namely, the pupil and the pneumogastric nerve. If, after several weeks' poisoning, the administration is stopped, the heart returns to the normal condition in from three to five days. It is suggested that the *modus operandi* of atropine on the heart is as follows: The first doses act exclusively upon the pneumogastrics; the excito-motor ganglia and the muscular tissue of the heart resist the action of the poison, and are only affected by repeated doses: hence the persistence of the retardation which succeeds the initial acceleration.

The same investigator has studied the action of cocaine, the active principle [illegible] the cocoa-leaves. He draws the conclusion that cold-blooded animals are mo sensitive to its action than warm-blooded animals. Its chief action appears [illegible] be upon the nerve-centres. In frogs, it first paralyzes the terminations of th sensitive nerves, and afterwards abolishes reflex action. In the mammalia, [illegible] first stimulates all the nerve-centres, and especially the psycho-motor centre This general excitation is followed by a slight enfeeblement. Small dose increase reflex action; large doses do not paralyze it entirely, as in the cas of the frog. Respiration is quickened, except by fatal doses. In frogs the power of the heart is lessened, so as to lead to arrest in diastole. In mammal the heart's action is accelerated, and strong doses are necessary to cause a retar ation. The blood-pressure is increased by the stimulation of the vaso-mo centres; large doses should naturally have the opposite action, and lower [illegible] blood-pressure. The inhibitory nerves of the heart are readily paralyzed [illegible] medium doses. The striated muscles are not directly influenced by cocain The pupil is dilated by it, and as powerfully by the internal use of the drug [illegible] by its instillation into the eye. The peristaltic movements of the intestine [illegible] accelerated. Acute poisoning by cocaine causes muscular spasms, and, in co sequence, an elevation of the rectal temperature; when there are no convulsio the rectal temperature falls. The secretion of the several mucous membranes [illegible] lessened. Certain motor disturbances can only be explained by the assumptio that cocaine has an action upon the semicircular canals; the symptoms sugge that the drug modifies the pressure of the endolymph in the internal ear, an thus effects a stimulation of the terminal filaments of the auditory nerve. Deat appears to result from asphyxia, caused by respiratory paralysis, the heart continuing to beat for some minutes after apparent death.

The action of cyanogen has been the subject of an experimental study by R. BUNGE, at Dorpadt, with frogs. He was unable to observe any convulsive phenomena, and the paralyzing effect was produced slowly, even with large doses. If the animals were examined after a few minutes' exposure to the action of the gas, the cutaneous sensibility was found to be lessened or abolished, and their movements were considerably lessened. During the first few minutes of the exposure the animals were restless from the local irritation, their movements then became slower and less frequent, the respiratory and cardiac action ceased. and rigor mortis set in with great rapidity. The latter, indeed, sometimes commenced in the hind legs while respiration was still going on. Post-mortem examination showed the heart to be dilated and filled with pale blood, in which the spectroscope revealed the absorption bands of oxyhæmoglobin. If the blood-supply to a limb was cut off, the rigor mortis appeared in those muscles somewhat later than elsewhere. If, however, a limb was entirely separated and exposed to the action of cyanogen gas, the cadaveric rigidity rapidly appeared in it. If the heart was exposed, the ventricular contractions were seen to become less frequent and more feeble, and the irritability of the cardiac muscle to mechanical stimuli was soon lost. This was, however, preceded by a transient acceleration of the frequency of the heart's action, which the experimenter refers to stimulation of the cardiac ganglia, or muscle substance. That it is not due to any action on the vagi is shown by the fact that, if muscarin is first applied so as to arrest the action of the heart, the stimulating effect of the cyanogen can still be observed. The chief difference between the action of cyanogen and hydrocyanic acid consists in the persistence of the respiratory movements after the heart's action has ceased, and in the early occurrence of the rigor mortis. In the mammalia, cats, rabbits, and mice, the cyanogen gas, whether inhaled or injected in watery solution into the blood, causes dyspnœa, and the animals die from respiratory paralysis, just as after poisoning with hydrocyanic acid. The blood-pressure falls, and the heart's contractions are at first rendered more frequent, but in the later stage are retarded. They continue after respiration has ceased. The toxic effect of cyanogen is less violent than that of hydrocyanic acid, .02 grm. being required to produce the same effect as .004 grm. of the latter.—*Lancet*, July 31, 1880.

Therapeutic Uses of Pilocarpin.

Pick (*Vierteljahres. für Derm. und Syph.*, 1880, Heft 1) has made a trial of pilocarpin in various forms of skin diseases. In most cases, a dose of one centigramme given internally twice daily stimulated first the secretion of saliva, and four or five minutes later that of sweat. In all the cases in which decided effects were produced, the action became less powerful after three or four weeks, so that, in order to secure continuance of effect, the dose had to be increased. If it were discontinued altogether for eight days, the same dose, on being again given, produced the original effects. When pilocarpin had been taken for some time, the skin became softer and more yielding, and the sebaceous secretion more abundant. No ill effects were observed. In prurigo (Hebra) it stimulated the secretion of sweat on the affected skin after a few weeks, and speedily alleviated the disease. In periods varying from 48 to 105 days the skin became healthy. Relapses supervened, but the diseased condition was not so intense as that previously existing, and was speedily relieved by the renewed exhibition of the drug. Against psoriasis, even in doubled doses, it proves valueless. In the acute stage of eczema it was injurions. In the chronic stage, with infiltration, it was, on the contrary, beneficial. Three cases of hemorrhoidal eczema were cured by it after they had resisted other treatment for years. Two cases of pruritus senilis were cured by it; in one it failed; in a case of pruritus vulvæ, following delivery, recovery was complete in three weeks. Recovery also followed its use in urticaria chronica. Encouragingly, but less decisively, the author speaks of its use in alopecia with pityriasis.—*London Med. Record*, July 15, 1880.

Method of Masking the Odour of Iodoform.

Tannin, which was recommended by Moleschott as a means of hiding the unpleasant smell of iodoform has not been wholly successful. Ether, which conceals the odour, on account of its great volatility is only useful for a short time, whilst oil of peppermint has not answered its expectations. Dr. Lindemann of Münster contributes to the *Allg. Med. Centralzeitung* an account of experiments which he has made with several preparations in regard to this subject. The conclusion at which he has arrived is that the balsam of Peru completely masks the smell of iodoform, and renders it imperceptible to the most delicately organized. He mixes two parts of the balsam with one part of iodoform, and recommends vaselin as being the best medium for an unguent; it may also be employed in an aqueous solution. The following useful formulæ are subjoined: ℞. Iodoform. 1 gram., bals. peruv. 2 gram., vaselin. 8 gram. M. f. ungt. ℞. Iodoform. 1 gram., bals. peruv. 3 gram., spir. vin. rectif. or glycerin. 12 gram. In regard to the preparation of these prescriptions, the author recommends that the iodoform should first be mixed with the balsam, and that the vehicle should afterwards be added.—*Practitioner*, July, 1880, from *Schweiz. Correspbl.* 20, 1879.

The Use of Quinia in Connection with Nervous Sedatives.

At the late meeting of the American Neurological Association Dr. LANDON CARTER GRAY, of Brooklyn, reported that great relief was to be expected from the bromides in robust patients: but not to the same extent in the case of the weak and anæmic. His own experience had convinced him that there was considerable danger in using them freely in certain instances, and he had met with one case in which a fatal result was thus produced. He was a firm believer in their efficacy in epilepsy, as a general rule; but at the same time he felt that under some circumstances they should be used, if at all, only with extreme caution. For the past two years he had been in the habit of prescribing quinine in connection with the bromides, and he could but express himself as more than satisfied with the results obtained by this combination. At first he had employed it with timidity and in very small doses, as he feared, from what he had been taught, that it might perhaps interfere with their action, and only aggravate the trouble present; but afterwards he had used it much more freely, and always with very beneficial effects. His practice now was to give first a sufficient quantity of the bromides to produce bromism, and then two or three grains of quinine three times a day in addition. He had met with a few cases in which quinine was not well tolerated, but as a rule such patients were able to stand the full sedation of the bromides; while in some instances he had deemed it advisable to stimulate the system with the quinine before commencing the use of the bromides, on account of the weak condition of the patient. All his experience went to show that quinine actually increased the effect of the bromides, hyoscyamin, and belladonna, and he had also found that all these agents were much better borne by the system, as well as more efficient in their action, when administered in combination with quinine than when the latter was omitted.

The happy effect of the quinine with hyoscyamin was well shown in a case of puerperal mania which he had seen in consultation. When hyoscyamin was given alone it seemed to be of no service; but when quinine was added to it, although there was no malarial complication in the case, its use was followed by the most happy results.—*Bost. Med. and Surg. Journ.*, July 8, 1880.

Medicine.

Tuberculosis as an Infectious Disease.

DR. L. G. BRYHN (*Norsk Magaz. für Lägevidensk* and *Nordiskt Medicinskt Arkiv*, Band xii.) relates some cases in proof of the infectious character of pulmonary tuberculosis, of which he has become convinced by observations made during a practice of thirty years' duration. A phthisical man married a woman of healthy family; the man died, the woman became phthisical, as did also her sister, who resided in the house during the man's illness. The latter married a man of great strength, of sound family; he, too, was attacked, and also his sister's daughter, who resided some time in the house. One of their children died of tubercular meningitis, two had signs of pulmonary tubercle, one was free. The girl who served the first man's wife became tuberculous, went home, and died. Her sister was infected by her; both their parents had lived to a great age, and tuberculosis had never before shown itself in the family.—*Lond. Med. Record*, July 15, 1880.

The Transmissibility of Tuberculosis by Milk.

M. Puech having recognized the existence of phthisis in a cow which was sold for killing, and yet continued to yield three or four litres of milk daily, fed with the milk two sucking pigs and two rabbits. He has communicated the following results to the Académie des Sciences. The animals, when killed, showed tuberculous lesions in strict proportion to the length of time the milk had been administered. These facts, according to M. Puech, show that phthisis is transmissible by milk direct from the cow. It remains to be determined whether this liquid loses its contagious properties when it is boiled. M. Bouley afterwards submitted to the Academy a jar containing fragments of the lung, liver, spleen, the phrenic centre of the diaphragm, and the bronchial and submaxillary glands of a pig, five months old, killed sixty-seven days after an inoculation of two cubic centimetres of meat juice, pressed with an hydraulic press out of a fragment of the ischio-tibial muscles of the tuberculous cow mentioned in M. Puech's note. This experiment was made at Toulouse by M. Toussaint of the Veterinary College. Examination of the fragments in the jar showed tuberculous lesions in a very advanced condition. M. Bouley said that these facts, which demonstrate beyond doubt the transmission of tuberculosis from the cow by the alimentary use of unboiled milk and the inoculation of the juice of uncooked meat, should not pass unnoted. In addition, they are not unique, since in Germany, experiments of the same kind have been made, and have yielded identical results, to which, however, it does not appear that sufficient importance has been attached. The danger is, according to M. Bouley, indubitably a real one; and it is well that the public should be warned of it, so that they may take proper precautions, especially as the use of raw meat is now often prescribed as a remedy for anæmic disorders. The outcome of these facts is, that inspection in regard to phthisis occurring in cows should be extremely strict in the slaughter-houses, and that it would be prudent to make use of boiled milk, especially for the feeding of infants, when the source whence it is derived is not beyond suspicion. Cooking, which destroys cellular and parasitic life, should render both milk and meat harmless.—*Brit. Med. Journal*, July 31, 1880.

Treatment of Infantile Paralysis.

Dally, in this exceedingly able and instructive paper (*Journal de Thérapeutique*, March 10th), prefaces his remarks by a definition of the disease and a description of the present views as to its morbid anatomy. This he does, since great misapprehension has existed by confounding several very different diseases, some curable, others not, under the title of infantile paralysis, and thereby he makes it quite clear to what ailment he refers. The essential paralysis of children is clinically characterized by a sudden onset without prodromata, generally feverishness and of short duration; paralysis rapidly supervenes, and, in twelve or twenty-four hours, is usually complete. After the first week movements reappear here and there, but often some limbs or some scattered muscles remain paralyzed and atrophied, such paralysis becoming the cause of very various deformities. Dr. Dally quotes from M. Buchheim's article on the spinal cord in the *Dictionnaire Encyclopédique des Sciences Médicales*, the description of the morbid anatomy of this affection. Referring to the various observations of Laborde, Cornil, Prevost, Vulpian, Lockhart Clarke, Charcot, Geoffrey, Roger, Damaschino, Parrot, and Jeffrey, extending from 1861 to 1871, he proceeds to sum up the results as being sclerosis, or simple atrophy of the antero-lateral columns of the cord, and granular disintegration of the large cells in the anterior cornea, the latter being a constant lesion The question as to whether the degeneration of the nerve-cells is secondary to the pressure caused by sclerosis of the spinal cord, or whether the atrophy of the nerve-elements is primary, he leaves unanswered; indicating that Charcot and Vulpian support the latter view, as Roger and Damaschino incline towards the former. The sudden onset, the diminished faradaic contractility, and the rapid muscular atrophy, all point to a primary affection of the nerve-cells, which alone may be sometimes found affected. Speaking of the cause of the disease, Dr. Dally points out that no diathesis, or hereditary predisposition, nor the usual accompaniments of growth, will account for it, but refers to a case that came within his own knowledge, and which he has previously placed on record, of three children in one family who were attacked, two in one day, and the other within twenty-four hours, that almost justified the suspicion of some poison being the cause. The cases were seen by Trousseau, Duchenne, and others, and no doubt as to the nature of the malady existed. Coming to the main purport of the paper, the writer, following Laborde and Duchenne, divides the treatment into three periods: 1. That for the acute phenomena of the onset; 2. For the paralysis and atrophy; 3. For the subsequent deformities. In respect to the first stage, Dr. Dally confesses to having had no experience of it; but assuming that a stage of vascular congestion precedes the destructive state, he agrees with the treatment recommended by Duchenne, Laborde, Simon, and Bouchut, and which may be summed up as means for withdrawing the blood from the vertebral region by the ventral decubitus, manipulation, sinapisms, etc., to the calf, and intestinal derivatives, especially calomel. The diet should be milk. Following the recommendation of Bouchut to employ the constant current, as Duchenne recommends the faradaic, he would only wait for the cessation of the fever to apply them to the affected muscles. The second period is essentially that of repair, spontaneously in the greater number of cases the disease limits itself when it is not completely cured. The problem is to prevent the sclerosis of the antero-lateral columns, which is secondary to the affection of the nerve-cells. Duchenne states that the application of local faradization at the commencement of the paralysis would cut short the duration of the paralysis, diminish, if not prevent, the atrophy of the muscles, and, perhaps, prevent their fatty degeneration. Keeping this dictum in view, Dr. Dally followed out the treatment in a dozen cases over periods of three weeks to three years with almost always the same results, viz., the re-establishing to a degree of the locomotive power, the prevention of deformities, and the arrest of the progressive atrophy. In one case, a perfect cure followed a complete paralysis, though the atrophy was less marked than usual. A further advantage is the prevention of atrophy of the bones, whereby, should the muscles eventually recover, the deformity of the limb is prevented. It is in reference to the treatment of the subsequent deformities that Dr. Dally makes some valuable remarks. He is rightly very severe upon the assertion too often made, that "the case will improve with age," a remark that, "however consoling it may be for the moment, is terribly false." "No improvement," he goes on to say, "follows age, nor the appearance of the menses, nor the changes of the moon, unless a happy chance or science interfere." He regards, also, as a most serious error, the indiscriminate use of gymnastics and exercise, as is often advised, since the deformity is due to the disturbance of the normal antagonism of the muscles of the limb one against the other by the paralysis of certain of them, leaving the others to exert their full force unneutralized. By exercise and gymnastics, this want of equilibrium is intensified and the deformity increased; since it is the healthy muscles alone that can participate in the exercise, the more they are developed by use the more do they deform the limb. The first rule, therefore, when inequalities in the limbs exist, is to supply the deficiencies by mechanical means; and the second is to limit the exercise and galvanism to the muscle or group of muscles which are paralyzed. The application of this rule will obviously vary with the part affected. Exercise is only applicable to those muscles which retain some contractility, and may be applied by directing the patient to perform the movement as far as he is able, resistance to such movement being made by the practitioner; or the latter may himself perform the movement of the limb, the patient being told to oppose such action as much as he can. The writer insists upon the persistent employment of the remedies, and warns against the expectation of rapid improvement, and compares the gradual advance made to the growth of the intellect by education. Galvanism the author regards as of most value for its direct and indirect trophic action, not so much on the separate organs as on the whole region. How far it alone is of value, he cannot say, since he has always employed it in conjunction with other remedies.—*London Med. Record*, July 15, 1880.

Secondary Degeneration of the Spinal Cord.

Amongst the contributions continually being made to the science of medicine, not the least important are the courses of lectures annually delivered by Professor CHARCOT at Paris, and uniformly published in the *Progrès Médical.* Of these there are two series: one being given at the École de Médecine by Dr. Charcot in his capacity of Professor of Pathological Anatomy to the Faculty; the other at the Hospice de la Salpêtrière in his capacity of Physician to that institution; and whether he be treating essentially of the anatomical side of disease, as in the former course, or of the clinical, as in the latter, Professor Charcot generally succeeds in introducing new and striking observations into his teaching, and in rendering his lectures interesting and suggestive, not only for his immediate audience, but also for the profession at large. The plan which M. Charcot adopts for his systematic course at the École de Médecine is each year to select some one branch of pathology, and to follow it up closely, rather than to extend his range over a wider area at the cost of thoroughness; and last year his choice fell upon the pathological anatomy of the so-called "systematic" lesions of the spinal cord. By the term "systematic" he means those lesions which, though extending throughout the greater part of the length of the cord, confine themselves more or less accurately to one region in its transverse section. Ever since careful microscopical examinations of diseased spinal cords have been made, it has been recognized that there is a strong tendency for morbid conditions to affect it in a curiously partial manner; that a lesion of one of the white columns, or of one horn of gray matter, tends to spread, not by involving the neighbouring white substance of other columns or other contiguous regions of gray matter, but by advancing along the column or horn of gray matter first attacked, until perhaps this portion of the cord is more or less affected throughout the whole of its extent. Familiar instances of this fact are to be found in the affection of the posterior columns seen in cases of locomotor ataxy, and of the anterior horns in infantile paralysis and progressive muscular atrophy.

This regional circumscription of morbid processes in the spinal cord is of great interest, not only from the pathological but from the physiological point of view. As was remarked by Professor Charcot at the commencement of his course, the study of the normal cord had done comparatively little to aid physiologists in elucidating the problems relating to its functions. The landmarks by which anatomists could divide it into separate regions are too few to be of much practical service; collections of nerve-fibres having widely different functions are tied together into a compact whole incapable of anatomical subdivision; and the organ is too small and too sensitive to allow of anything more than rough experiments being made by physiologists. Owing, however, to the tendency of various diseases of the spinal cord to pick out certain functional regions and to confine themselves mainly to these regions, it has become possible to arrive at much more accurate conclusions regarding the functions of different parts of the cord than had previously been the case; and there can be no doubt that the next few years will result in the discovery of many new facts to add to those which have already come to light.

One of the most interesting facts to which Professor Charcot called special attention in his lectures, was the existence of certain bundles of fibres in the antero-lateral columns, which are peculiarly liable to undergo secondary degeneration in connection with lesions involving the motor regions of the cerebral hemispheres. This secondary degeneration is seen in many cases of old-standing hemiplegia, and it affects two separate tracts situated on opposite sides of the spinal cord; for instance, a patient, who has suffered from left hemiplegia, the result of some lesion in the motor tract of the right cerebral hemisphere, will be found to have secondary degeneration of a band of fibres in the right half of the spinal cord forming part of the antero-lateral column, and lying close to the anterior median fissure; and of another band of fibres in the left half of the cord also forming part of the antero-lateral column, but situated in its posterior part. These bands are known as the "direct" and the "crossed pyramidal tracts" respectively. They differ from other portions of the white matter of the spinal cord, in being directly connected with the surface of the brain. This connection has been proved in two ways; first, by the fact that at the time of birth, when the rest of the spinal cord has arrived at a high degree of development, but the brain is still in a comparatively early stage, these particular bundles in the cord correspond strictly in their degree of development to that seen in the brain; they have not arrived at their proper relative size, and the nerve-fibres of which they are composed have not yet received their sheath of medullary substance. The second proof lies in the onset of the secondary degeneration above described. In both instances it is possible to trace the course of these fibres with fair accuracy. After passing up the cord to the medulla oblongata, they form the anterior pyramid of the body, the "crossed" band by its decussation giving rise to the well-known decussation of the anterior pyramids; thence they can be traced through the pons Varolii and crus cerebri to the posterior half of the internal capsule, by which they pass to the motor region of the cortex in the neighbourhood of the fissure of Rolando. They thus constitute a series of commissural fibres passing directly from the surface of the brain to the spinal cord, without communicating in their passage with any of the large ganglionic masses at the base of the brain. Any lesion of the brain which affects either those portions of the cortex from which they arise, or those portions of the internal capsule, of the crus cerebri, or of the pons in which they lie, will give rise to secondary degeneration of these tracts. On the other hand, no lesion of the large ganglia, of the anterior half of the internal capsule, or of any other portion of the cortex than that near the fissure of Rolando, will cause any change in these tracts.

The central origin and the course of the fibres composing the pyramidal tracts having thus satisfactorily been determined, it still remains to trace them to their peripheral destination. This has proved less easy than the former task. Only two solutions were at all probable; the one being that the fibres pass straight into the anterior roots of the nerves, and the other that they pass into the gray matter and become directly connected with the cells of the anterior horns, which would thus act as intermediary agents between them and the nerve-roots. Two facts oppose the first hypothesis. In the first place, the anterior roots are at birth highly developed, at which period the pyramidal tracts, as before stated, are in an embryonic condition. This does not seem as though the two sets of fibres can be directly continuous. In the second place, in cases where degeneration has become exceedingly marked in the pyramidal tracts, it is very rare to find any degeneration of the anterior roots of the nerves. On the other hand, some recent observations made by Professor Charcot and others tend to prove the direct connection of the fibres of the pyramidal tract with the large cells of the anterior horns. It is a well-known fact that these cells maintain the nutrition of the muscles; and as these cells almost always remain healthy in cases of hemiplegia, it is very rare to find marked degeneration of the paralyzed muscles in such cases. In certain instances, however, Charcot has seen rapid wasting of muscles on the paralyzed side supervene in patients suffering from hemiplegia, and in whom the presence of secondary descending degeneration had been indicated by rigidity of the paralyzed limbs, the symptoms most commonly seen in such cases. In these instances, he has invariably found after death that the degeneration involved the anterior horns in addition to the usual pyramidal tracts; and though he has not found it easy in practice to trace degenerated fibres from the pyramidal tracts to the cells of the anterior horn, he feels justified in assuming that the connection exists, and that the cell-degeneration is directly due to an advance of the retrograde change from the pyramidal fibres. Thus it has been possible to trace a fasciculus of nerve-fibres from its central connection with the cortex of the brain to its peripheral distribution in the muscles.

There is one other point of interest to which Professor Charcot called attention in connection with the pyramidal tracts. It has long been known that only a portion of the fibres forming the anterior pyramid in the medulla oblongata decussate, though it has generally been found that by far the larger proportion of the fibres do so. Some little time ago, Flechsig, to whose researches much of the information contained in Professor Charcot's lectures is due, published a series of observations on the anterior medullary pyramids. He ascertained that the decussation is liable to great variations, and he grouped these variations into three chief types. In the first type, there is a partial decussation, presenting the same characters on the two sides. In the great majority of cases the band of decussating fibres is very much larger than the band which does not decussate, generally in the proportion of ten or fifteen to one. But the proportion is very variable, and in extreme cases it is entirely reversed, only a very small proportion of fibres decussating. In the second type, a complete decussation takes place on both sides; whilst in the third type, there is partial decussation on one side and complete decussation on the other. To the wide variability in the amount of decussation seen in the case of the first type, we may trace the existence of those strange but well authenticated cases of hemiplegia in which the paralysis takes place on the same side as the lesion of the brain.

The change we have just described is a *descending* degeneration following a lesion higher in the cranio-spinal axis than the seat of degeneration. Professor Charcot devoted several lectures to the study of *ascending* degenerations; in other words, to those which occur in the spinal cord or its upward prolongation as the result of lesions situated *below* the degenerated fasciculi. Space will not allow us to go fully into these changes; but it may be said briefly that two sets of fibres are liable to undergo this degeneration: 1. A thin band forming the extreme outer portion of the posterior half of the antero-lateral column, and known as the "direct cerebellar fasciculus;" 2. That portion of the posterior column which borders the posterior median fissure, and which forms the well-known posterior median column of Goll. There is, in addition, a degeneration of the rest of the posterior column for a short distance above the seat of the original lesion. These degenerations only result when the original lesion occupies the white matter of the cord; a simple lesion of its gray matter, as in infantile paralysis or progressive muscular atrophy, being wholly powerless to produce them. It would appear, however, that ascending degenerations of this kind may occur, not only as the result of lesions in the spinal cord itself, but of disease of the nerves after their exit from the cord. At present, the number of clinical observations in proof of this conjecture is very small indeed, but it will probably be found that, when the attention of the profession has been more widely drawn to this series of phenomena, the number of strictly authentic cases of this nature will be largely increased.

We have given but a mere outline of the subject of secondary degeneration of the spinal cord, but we think we have said enough to indicate the great importance that attaches to them in the elucidation of the problems relating to the anatomy and physiology of the cord. Many points still require to be cleared up, but the surest way of arriving at a further knowledge of the functions of its different parts, is to combine full and accurate clinical observation of cases where these functions are modified, with careful microscopical examination of the cord in such cases after death.—*British Med. Journal*, June 26, 1880.

Fatal Chorea.

Mr. OCTAVIUS STURGES has recently made a study (*Lancet*, July 17, 1880 of some statistics of fatal chorea and deduces the following conclusions:—

1. Chorea, regarded as a disease of itself fatal, belongs almost exclusively to puberty, and especially to female puberty; its immediate exciting cause having distinct reference, in many instances, to conditions of unusual sexual excitement.

2. Besides the operation of sexual causes mental disturbance has to be reckoned; not fright only, but worry, anxiety, and despondency also, while the force and influence of such impressions is to be seen in the course as well as in the origin of fatal chorea.

3. Acute rheumatism appears as a cause of fatal chorea in but a small proportion of cases; yet the association, infrequent as it is, is distinct and unquestionable.

4. Chorea in its fatal, no less than in its non-fatal forms, shows strong preference for the female sex at all ages. Children, however, very rarely die of it, and boys, practically speaking, never.

5. Mental excitement, in varying degree (although not amongst the symptoms of ordinary chorea), is met with in so large a proportion of its fatal examples that we are justified in regarding this occurrence as of bad augury.

6. "Vegetations," new or old, on the auricular surface of the mitral valves, with or without similar deposits on the aortic valves, and sometimes with pericarditis, are met with in the great majority of cases dying of, or with, or shortly after, chorea. This condition, however, does not, as a rule, contribute directly to the fatal issue; it is found equally amongst those that die *with* and those that die *of* chorea. In some of the most marked and typical cases of fatal chorea the valves of the heart have been found absolutely healthy.

7. There is no other morbid condition except that which concerns the heart, ccurring with sufficient frequency or uniformity to be regarded as characteristic f fatal chorea.

On Nervous Phenomena of Gastric Origin.

At a late meeting of the Paris Academy of Sciences, M. LEVEN called par- icular attention to the gastric origin of a certain number of medullary and cerebral ervous phenomena, which have been frequently attributed either to hysteria r to hypochondria. Thus, in his opinion, neuralgia, dermalgia, muscular and rticular hyperæsthesia of the left side, thought to be caused by hysteria, are, as rule, irradiations from lesions of the stomach. In the same way hypochondria, hich alienist physicians describe as a special neurosis, frequently results, either om a dilatation of the stomach or from another affection of that organ. In pur- ance of the reigning opinion on the nature of these nervous phenomena, patients re treated by preparations of iron and quinine, which only aggravate the gastric oubles and dyspepsia. On the contrary, the affection of the stomach should be eated, and all the nervous irradiations will disappear with it. M. Brown-Séquard erved that it has long been known that all the organs, or, more correctly speak- g, all the nerves of the diseased organs, might bring on hysteriform phenomena; t it is very certain that the stomach shows disorders which are secondary, and pend on the general hysteric affection. M. Leven did not deny the subordina- n of the stomach to general neurosis, but he laid great stress on the fact that ery diseased organ induces special pathological reflexes.—*British Med. Journal*, ly 3, 1880.

Acute Respiratory Paralysis of the Larynx.

Dr. PAUL KOCH (*Annales des Maladies de l'Oreille, du Larynx, etc.*, May, 80) relates the following case. A girl, aged 7½ years, after one day's fever, ered from a large and deep ulcer, surrounded by a zone of intense red on the t tonsil. The margins were excavated; the surface dirty yellow. Similar eration appeared on the opposite tonsil the same evening. During the night oarse cough and dyspnœa, increasing in intensity, announced an invasion of e larynx. The following morning the cough was croupy, the voice was un- ected, but there were great dyspnœa and well-marked stridor, both exclusively piratory. No laryngoscopic examination was made, but the author concludes t ulceration similar to that on the tonsils, had taken place on the retro-laryngeal ucous membrane, and that it had produced an œdematous infiltration of the ators of the glottis, the dyspnœa being characteristic of paralysis of the poste- r crico-arytenoid muscles. Under continued inhalation of a saturated solution chlorate of potash, the dyspnœa rapidly disappeared.—*London Med. Record*, ly 15, 1880.

Quebracho in Dyspnœa.

In an article on the treatment of asthma (*Brit. Med. Journal*, July 17, 1880) Dr. J. B. BERKART states that the liquid extract of quebracho has of late been largely employed in the treatment of asthma. As yet, there is no indication for its use, except the presence of dyspnœa. A teaspoonful, repeated, if necessary, at intervals of ten minutes, certainly relieves, as he has observed, the dyspnœa of phthisis, of pneumonia, of pleurisy, of emphysema, and of valvular lesions. It has failed of its effect, so far as he has seen, only in two cases of aortic disease; in the one, the patient had been for years accustomed to inhale nitrite of amyl almost every two hours: in the other there was complication with marked attacks of stenocardia. The active principle of quebracho appears to be a gum-resin; but as to its mode of action nothing is known. Dr. Berkart has frequently noticed that after the administration of the drug, there is slight flush of the face, perspiration, and occasionally drowsiness; but there are no objective signs on the part the heart and of the lungs sufficient to account for the relief.

Peculiar Disease of the Intestines.

Dr. **Helweg** relates, in the *Hospitals-Tidende*, Series 2, Band vi. (abstract i *Nordiskt Medicinskt Archiv*, Band xii.) the case of an insane peasant, aged 4 who had for many years suffered from constipation, pain in the abdomen, a swelling in the ileo-cæcal region. The symptoms came on when he was out bed; they were relieved when he was lying down; and at last he was obliged t remain in bed continually. He had about every month an attack of disorder the digestive organs, constipation or diarrhœa, which lasted about ten days. I May, 1878, an indolent tumour, feeling like a loop of intestine, and yielding tympanitic sound on percussion, was detected in the right iliac fossa. On de pressure, a sort of crepitation was felt in it; it sometimes suddenly disappear when friction was made, and reappeared after an interval varying from a f minutes to a day. The patient died on December 21, 1878, with symptoms meningitis at the base of the brain. At the necropsy, miliary tubercles w found in the pia mater, lungs, and liver. The upper part of the cæcum and t lower part of the colon were much distended with gas; then came two contract portions of colon, separated by a distended portion of the bowel filled with g the portion of the intestine on the other side of the flexure of the colon was n mal. In the first of the contracted portions of the colon, the mucous membr formed a sponge-like tissue, the meshes of which and the intestinal space w filled with round scybala; in one place, there were two straight channels ly parallel with the proper lumen of the gut. In the other contracted portion, t mucous membrane was thickened, but not spongy. On microscopic examinati it was found to have the ordinary structure of intestinal mucous membrane.

Treatment of Parenchymatous Nephritis with Pilocarpine.

Dr. **Cortezo**, in the *Siglo Medico* of June 6, 1880, reports three cases of par chymatous nephritis treated by means of hypodermic injections of pilocarpi The first case was that of a man, aged 30, somewhat addicted to alcoholic drin but whose medical history was otherwise good. On admission, all the sympto of albuminuria, including well-marked retinal changes, were present. He was first placed upon a strictly milk diet, but this treatment proving of little use, it subsequently changed for hypodermic injections of pilocarpine. One centigram of the alkaloid was used daily, or every alternate day, during a period of thi days. At the end of this time no trace of albumen could be found in the patien urine. The second case occurred in a man, aged 42, who, some years previous had suffered from general motor paralysis, with partial loss of sensibility. T affection had been followed after a lapse of two years by well-marked sympto of renal disease. The urine contained numerous hyaline casts, and albumen, the amount of 4 grammes (1 drachm) to the litre. Hypodermic injections of centigramme of pilocarpine were given during a period of twenty days, and th discontinued for ten days, during which interval all traces of albumen disappear The patient was discharged apparently in excellent health. The third case was th of a man, aged 42, whose urine had for some weeks presented traces of albume Œdema of the eyelids and of the lower extremities was present. The same qu tity of the alkaloid was injected daily during four days, after which no album could be detected in the urine.—*London Med. Record*, July 15, 1880.

Pilocarpine in Uræmia.

M. Boegehold (in the *Deutsche Medicin. Wochenschrift*, No. 26, p. 331, 1879; and *Gazette Hebdomadaire*, January 30, 1880, p. 75) relates four cases of undoubted uræmia, in which pilocarpine was employed in the form of subcutaneous injection. The first case was one of a child 5 years old. Acute uræmia supervened during convalescence from scarlatina; 8 milligrammes of pilocarpine were injected, and the convulsions ceased. At the end of an hour she had regained consciousness. Another attack supervened at the end of a few days, which was cured by two similar injections. The injections were made regularly during twenty days, and the attacks were not renewed. Ten days later on, the albumen had disappeared, and the cure was complete. In the second case, a boy 12 years of age was attacked by uræmic convulsions during convalescence from scarlatina. Injections of 1 centigramme of pilocarpine put a stop to the convulsions at the end of six minutes in two different attacks. Cure was effected. In the third case, the injections stopped the convulsions, but death supervened during coma. In the fourth case, the patient was seven years old, and had chronic nephritis. The convulsions ceased under the influence of injections of pilocarpine, but the child succumbed to the progress of the disease. The results obtained by the author seem to indicate that pilocarpine may be an useful agent in combating one of the most alarming and dangerous symptoms, but its utility in relation to the disease itself is certainly doubtful. However, as it stops convulsions, it may perhaps be used with advantage in puerperal eclampsia; a point which merits attention.—*London Med. Record*, July 15, 1880.

Surgery.

Perfectly Bloodless Operation.

The bloodless method of operating recommended some years ago by Esmarch, is opposed by many surgeons on account of the general oozing which is apt to occur after removal of the elastic tube. Esmarch describes here (*Verhandl. d. Deutschen Geselsch. f. Chirurg. Apl.* 1880) the latest practical modification of his mode of procedure, by means of which such oozing may be completely prevented. In amputations, the operation is performed in the usual way by the bloodless method; all vessels requiring ligature are then carefully sought out and tied, and the wound at once closed with catgut sutures; drainage tubes, capable of being absorbed, are introduced, and Neuber's permanent compressing dressing applied. Then, and not till then, is the elastic tube removed from the limb. After the patient is placed in bed, he should keep the stump up in the vertical position for at least half an hour. [Neuber's permanent dressing consists of an antiseptic cushion, four-cornered, made of carbolized gauze filled equally and smoothly with carbolized jute; this cushion is applied directly to the wound, and is kept firmly in place by an elastic bandage which overlaps the dressing.] Of twelve amputations (9 of the leg) performed and treated in this way, secondary hemorrhage occurred in none; in most of them the first dressing was not removed for 14 days, and on it was then found only a narrow, dry streak of blood, corresponding to the linear cicatrix. In resection the author advises that after all visible ends of vessels have been tied, the wound should be closed with the continuous glover's suture, and that the limb should then be made fast to a splint and kept elevated for at least half an hour. In 56 resections managed in this way since 1878, neither secondary hemorrhage nor death had occurred. Since

Easter, 1879, the author had also, in his operations for diseased bone, given up the practice of plugging the cavity from which the sequestrum had been removed; instead of this he now carefully disinfects the cavity, introduces absorbable drainage tubes, closes the wound in the skin at once, and applies the permanent dressing; the last step in the proceeding is, as before, the removal of the elastic tube. Twelve cases were treated in this fashion, and in none of them did secondary hemorrhage occur; in all of them the wound remained aseptic, and in several instances complete primary union took place. Esmarch also states that he has frequently adopted, and with similar results, the same method in various other operations on the extremities, such as the removal of tumours from these parts; in the neighbourhood of the shoulder and hip-joints, however it is a matter of much greater difficulty to carry out the above directions, and so to obtain a perfectly bloodless operation.—*Glasgow Med. Journ.*, Aug. 1880.

—

The Radical Cure of Cancer.

Professor KOCHER of Bern, in a contribution to the *Deutsche Zeitschrift f Chirurgie*, Band 13, Heft 1, 2, on the surgical treatment of cancer, insists the importance of removing not only the part primarily diseased, but likewise affected glands. The proximal set of lymphatic glands should, it is stated, always removed, since, in most cases of superficial cancer brought under t notice of the hospital surgeons, those adjacent structures are already affecte The author's paper is one of much interest, as being a record of the results th have followed the performance of radical and formidable operations for the r moval of cancer. Twenty-nine cases of this kind are reported, in five of whi pharyngotomy was performed; in fourteen, excision of more or less of t tongue; and in ten, removal of cancer of the rectum. In four only of all the cases did the operation cause death, and in nine of the remaining twenty-fi cases radical cure is believed to have been effected. In this set of cases, in whi surgical procedures of great danger and difficulty had been applied for the tre ment of a disease with most unfavourable prognosis as to recurrence, the mo tality was somewhat less than 14 per cent., and the proportion of complete cu about 31 per cent. The reduced mortality is attributed by the author to h endeavour to carry on as far as possible an antiseptic method, and the number radical cures to his practice of removing with the primary seat of the disease accessible diseased glands, and cutting in a direction from the affected glands the original seat of the disease. Of the five patients in whom pharyngotomy w performed by Professor Kocher, one died on the thirty-sixth day from pneumo nia, two died from speedy and one from late relapse (two years), and the fift when last seen, was quite free from disease three years after the date of th operation. The operation of pharyngotomy has, with regard to its immediat results, been attended with exceptional success in the practice of Professor Kocher, but in most of these cases some portion only of the posterior or latera walls of the pharynx was removed, and a less severe surgical proceeding seem to have been needed than in the fatal cases treated by Von Langenbeck an Gussenbauer. The chief danger, however, attending the removal of the whol or of a portion of the pharynx, is the passage of food into the air-passages during deglutition, and consequent pneumonia. This evil Kocher endeavours to guard against by tracheotomizing the patient in the first stage of the operation, the cannula being allowed to remain during the after-treatment, and the entrance to the œsophagus being plugged by a piece of sponge dipped in some antiseptic solution. The patient is supplied with food, at certain intervals, by means of a tube passed into the œsophagus under the carbolic acid spray.

Kocher regards preliminary tracheotomy as an indispensable proceeding in pharyngotomy. The superior is preferred to the inferior operation, as it is less likely to be followed by obstinate venous hemorrhage. The passage of blood into the trachea is prevented by plugging of the orifice of the larynx with a small piece of disinfected sponge. This plug is introduced after exposure of the deeper structures, and when the patient is thoroughly under the influence of an anæsthetic. It should be renewed frequently during the operation and whenever it is saturated with blood. The application of Trendelenburg's distensible ball-plug to the interior of the trachea is believed by Kocher to be attended with much difficulty. In order to reach the diseased portion of pharynx, an extensive incision is made, so as to form three flaps. The knife is carried from over the lower margin of the inferior maxilla, at or near the symphysis, downwards to the hyoid bone, and then laterally to the anterior margin of the sterno-mastoid muscle; from the posterior extremity of this incision, the knife is carried upwards towards the external ear, and along the ascending ramus of the jaw, and downwards to the superior and posterior part of the larynx. The superficial portion of the submaxillary gland, together with the adjacent and adherent lymphatic glands, is next removed. In this stage of the operation, the lingual and facial arteries are secured by double ligatures and divided. The laryngeal orifice having been plugged by a piece of sponge, the mylo-hyoid muscle is divided near its attachment to the lower jaw, so that the finger can be carried into the mouth, and be passed backwards so as to feel the extent of the disease in the pharynx. The inferior portion of the diseased structure is dissected away carefully from below and through the wound, whilst its superior limits are divided from the mouth. When the lateral wall of the pharynx, together with the tonsil and a portion of the soft palate, are involved in the disease, this part of the operation will be much facilitated by division of the inferior ramus of the lower jaw, which permits elevation of the ascending ramus and free exposure of the structures beyond. This proceeding should not, however, be carried out, Kocher states, save when urgently required, since it often results in the formation of a permanent false joint. During the subsequent treatment, the deeper portions of the wound, together with the entrances into the respiratory and digestive tracks, are covered by a piece of sponge previously disinfected, which is frequently renewed under the spray. The patient is fed twice in the day by fluid nutriment introduced through an œsophageal tube. Kocher claims as the advantages of his extensive and irregularly shaped wound, compared with the long straight incision practised by Von Langenbeck, that it allows much more exposure of the affected parts, and freer removal of the disease; that it enables the surgeon to plug the orifice of the larynx and œsophagus, and that it facilitates deligation of the numerous arteries divided during the operation, and so reduces the extent of the bleeding.

Fourteen cases of the removal of lingual cancer are recorded. In most of these, considerable portions of the tongue were removed, and one was a case of total extirpation. One patient died shortly after the operation from secondary hemorrhage and pneumonia; of the remaining patients, eight suffered from relapsing cancer, whilst five, including the case in which the whole of the tongue was removed, are regarded by Kocher as cured. Of the latter, one patient was living and free from disease eighteen months after the date of the operation; in two cases there was an interval of five years; and in one case an interval of six years and a half. In none of the reported cases of relapse after operation was the duration of the case, from the first appearance of the symptoms, longer than twelve months. In all the cases of supposed radical cure, the operation had been performed at an early stage of the disease, and before any apparent glandular affection.

Kocher, in discussing the kind of operation for the removal of cancer of the tongue, states that the surgical procedure most likely to be followed by succes is such as will best favour, in the first place, a ready control and arrest of hemorrhage; in the second place, a free exposure of the field of operation, so that the smallest lymphatic glands may be seen, and, if necessary, removed; and, lastly, a free flow of buccal secretion during the subsequent treatment. None of these indications are fulfilled by attacking the disease from the mouth, a method to b practised, it is held, only in cases of small and circumscribed cancerous deposit at the tip of the tongue. Kocher operates from the neck, but his method differs considerably from that of Regnoli, in the wound being made on the side and no in the front. Division of the lower jaw is unnecessary, it is thought, save i cases in which the floor of the mouth is involved in the disease, and the infiltrate soft structures cannot be freely moved over the inner surface of this bone. I such instances, partial resection of the jaw would probably be found preferabl to simple division. In Kocher's operation, devised with the aim of removin adjacent glands, as well as more or less of the diseased tongue, a large flap skin having been made by an incision carried along the anterior margin of th sterno-mastoid muscle, and by a second carried from the posterior extremity the first to the body of the hyoid bone, the submaxillary and adjacent lymphat glands are removed, and the mylo-hyoid muscle exposed. This muscle, togeth with the buccal mucous membrane, having been divided near the lower jaw, th side of the tongue, from apex to base, becomes freely accessible. The galvan cautery has certain decided advantages over the écraseur; it may be appli with much more precision; it guards against diphtheria of the raw surface tongue, and, according to the experiences both of Billroth and of Kocher, application is less likely to be followed by relapse. When used slowly, it seld causes any primary hemorrhage, but in many instances the separation of t eschars is attended with serious secondary hemorrhage. If the operation can performed slowly, and all divided vessels can be immediately secured, the di eased portion of tongue may be best removed by a cutting instrument, deligati having been practised on one, or, in case of total extirpation, on both lingu arteries. With regard to the danger of secondary hemorrhage, the cutti operation, Kocher states, is the safest, indeed the only safe operation. It is he that a great step in glossotomy has been made by Mr. Barker, of Universi College Hospital, who has practised preliminary tracheotomy in this operatio With the retention of the canula during the after-treatment, the oral and na cavities may be kept closed, and the wounded surfaces be protected by antisep dressings.

Of the ten cases of cancer of the rectum in which the disease was removed b surgical operation, two terminated speedily in death, three others in death aft relapse, and four resulted in supposed radical cure. In the fatal cases and tho of relapse the cancerous disease was of considerable extent, and the patients we not submitted to that particular method of operation lately practised by Köni and regarded by him as most effectual with respect to the control of primar hemorrhage, the prevention of local infection, and the radical removal of th disease, both in the gut and in its lymphatic glands. The plan of dissecti upwards from the anus is rejected, and preference is given to a long medi incision behind the anus, and in the posterior gap between the buttocks, so as t expose the posterior surface of the rectum, and to permit a dissection of th lateral and anterior walls from the surrounding soft parts. In this operation, diseased glands can be readily removed from the hollow of the sacrum, and this proceeding is carried out before the dissection of the gut. When a considerable extent of gut is involved in the disease, the coccyx is excised. König does not attach much importance to any attempt to bring down and fix the margins of healthy mucous membrane to the margins of the external skin-wound at the anus. The sutures usually tear away, and, by covering the raw surfaces by mucous membrane, free discharge of wound secretions is obstructed.

Free removal of cancer of the rectum has, on the whole, been attended by very good results. In one of König's cases the patient was living, and free from disease, eight years after the operation, and in three other cases there has been no return after intervals of three, five, and seven years. As Volkmann, however, has reported cases in which there had been intervals of six, eight, and eleven years between the date of the operation and the occurrence of relapse, it is open to doubt whether in the cases recorded by König the patients can fairly be regarded as radically cured.—*London Med. Record*, July 15, 1880.

Scleritis and Sclero-Keratitis.

In an article on the treatment of inflammation of the sclerotic (*Recueil d'Ophthalmologie*, May, 1880), Dr. GALEZOWSKI insists on the importance of clearly distinguishing between scleritis confined to portions of the sclerotic distant from the corneal limbus, and scleritis occupying the limbus. In the former case, the disease, though obstinate, is, as a rule, curable, and will leave no external traces upon the eye nor permanently interfere with vision. The second variety, on the contrary, is frequently followed by grave complications in the cornea and iris, and may lead to permanent blindness. Both forms are intimately connected with a rheumatic or gouty diathesis, but may also be dependent on the presence of struma. As regards treatment in the first-mentioned variety of the affection, Dr. Galezowski has developed a certain procedure, which has given him excellent results. He first of all has recourse to alternate instillations of atropine and eserine, using the former twice a week, the latter every day. He then applies flying blisters to the forehead and temples, and uses ocular douches of steam. Internally, salicylate of soda is administered, in daily doses of from 2 to 4 grammes, with hypodermic injections of pilocarpine. In scleritis of syphilitic origin, he places his chief reliance on iodide of potassium. Each of these stages of treatment is illustrated by reported cases. In certain instances the author has found great benefit from scarifications at long intervals of the inflamed and swollen surface of the sclerotic. The incision should be perpendicular to the corneal border, and should extend down to the sclerotic. If done once every ten or twelve days, a single incision will often suffice to arrest the further progress of the affection. The second variety of scleritis, viz., sclero-kerato-iritis, is always localized at first in the ciliary region, very near to the corneal border, whence it spreads progressively to the cornea and the iris. In such cases, the author considers there is only one really efficacious treatment, viz., iridectomy. In most cases the pain is at once relieved, and within ten or fifteen days after cicatrization has become established, the swelling and redness disappear, and the affection is cured without danger of relapse. In support of this doctrine, he gives the histories of two cases. In one the affection has proved rebellious to all treatment, and the cornea was becoming gradually infiltrated throughout its whole extent. There was also very intense periorbital pain. Iridectomy gave immediate relief, and subsequently removed all the symptoms. In another, a strumous girl had suffered for several months from sclero-keratitis. Both eyes were affected; there were interstitial deposits in the cornea, posterior synechiæ, and symmetrical inflammation of both sclerotics. In this case, also, the results obtained by iridectomy were most satisfactory. The author concludes by stating that he considers the above operation to be the only successful plan of dealing with these troublesome cases.—*London Med. Record*, June 15, 1880.

Choroiditis after Relapsing Fever.

According to TROMPETTER, in a recent epidemic of relapsing fever (febris recurrens) in Breslau (*Klin. Monatsblätter für Augenheilkunde*, April, 1880), acute choroiditis or cyclitis occurred in 21 out of 325 cases, *i. e.*, in about 6 per cent.—a higher proportion than was observed in the previous epidemic. The ocular disease began either late in the course of the fever, or after its termination. Hypopyon was of frequent occurrence, but disappeared under treatment; the iris was unaffected. The vitreous humour was invariably clouded. Acuity of vision, and light perception, were much impaired at the outset; the visual field was peripherally contracted, indicating probably, that the disease affected chiefly the anterior part of the choroid and the ciliary body. The course of the choroidal affection was almost always favourable. It lasted commonly from one month to si weeks. In two cases, both eyes were affected. Embolism or metastasis fro splenic abscesses, which constantly occur in relapsing fever, is believed by th writer to be the cause of the choroiditis. Atropine locally and mercury internally, with laxatives, constituted the treatment.—*London Med. Record*, July 15, 1880.

Epileptic Amaurosis.

CHRISTENSEN relates in the *Ugeskrift for Läger*, second series, Band (abstract in *Nordiskt Medicinskt Arkiv*, Band 11) the case of a married lady aged 33, of healthy family, who, since her first menstruation in her twelfth ye had had attacks of loss of consciousness, sometimes with convulsions, followed blindness of several hours' duration. These attacks occurred at each menstru period, and ceased with the appearance of the catamenia. From her eighteen year the convulsions became more severe, but the sensory impairment grew mo rare and weaker. In December, 1872, the convulsions and catamenia did n occur; but after several days' headache and giddiness, she became blind in th course of an hour. The fundus of the eye was normal. Under the use of leech and counter-irritants the headache ceased. Some days afterwards she had an epileptic attack, in which there was considerable hyperæmia of the optic disk a retina. She menstruated in January, and her sight began to return. After so months her vision was =½, with blindness to red; the disk was somewhat atrophied. Four years later she had a similar attack of blindness, but not complet Vision returned after the appearance of the menses, but again failed, and progressive atrophy of the optic nerve now commenced. The author believes the mo probable proximate cause to have been hyperæmia or inflammation of the opti nerve behind the bulb.—*London Med. Record*, July 15, 1880.

Case of Acute Glaucoma.

Dr. COURSSERANT relates this case in the *Journal des Connaissances Médicales*, April 15, 1880. A man, aged 47, suffered from chronic gastritis with acut crisis. During three months each crisis was accompanied by prodromata of glaucoma, which disappeared during the intervals. Finally, a violent unilateral acut glaucoma set in during a crisis and persisted after its remission. Iridecto restored vision almost to its normal acuity, and eight months later this eye ha suffered no relapse. The other eye, similarly attacked during a gastric attack, was relieved by eserine, and permanently benefited by iridectomy. Reflex actio pon the vaso-motor system in the eye is suggested as the cause of the glaucoma. —*London Med. Record*, July 15, 1880.

—

Case of Convergent Strabismus of Intermittent Character.

Dr. SAMELSOHN relates the following case in the *Centralblatt für praktische ugenheilkunde*, April, 1880. A girl, aged 12, presented strong inward deviaion of the right eye. Both eyes were slightly hypermetropic; in both there were ight corneal opacities; an examination with prisms revealed a remarkable indifrence to diplopia. The strabismus existed only on alternate days; during the tervening days no trace of deviation, even with the eye covered, was discoverble. The examination was repeated daily, and at various times of day, for weeks gether, and showed that the squint maintained an intermittent character of reglar tertian type. Quinine and arsenic had no influence over it.—*London Med. ecord*, July 15, 1880.

New Operation for Entropium of the Lower Lid in Old People.

The aim in operations for relief of entropium is to make, by the removal of a d of skin or the formation of a cicatrix, such a traction upon the tarsal carlage as will prevent its inversion. HOTZ urges (*Klin. Monatsblätter für ugenheilkunde*, May, 1880) that to be efficient such traction requires a fixed oint below, and that the lax integument of the cheek does not afford this reirement. The lower border of the tarsal cartilage, being bound by the fascia the orbital margin, is, as regards all vertical traction, a fixed point. The steps the operation advised are, briefly, as follows: A horizontal incision is made rough the skin at a distance of 4 to 6 millimetres from the edge of the lid, and eching from the inner to the outer canthus, so as to separate the skin of the lid m that of the cheek just over the lower margin of the tarsal cartilage; the of the incision are widely retracted, and that portion of the orbicularis muscle ich covers the lower edge of the tarsal cartilage is removed; silk sutures, genlly four, are introduced so as to obtain union of the cut edges of the skin th the exposed lower margin of the cartilage and adjacent fascia. A curved edle is passed first through the skin of the lid close to the cut edge, then rough the lower edge of the cartilage and out again through the adjacent fascia, d finally, without any inclusion of any fibres of the orbicularis, from within outrds through the skin of the cheek close to the cut edge. Special details and ecautions are given. Excellent results are stated to have been obtained, and tably when previous operation by excision of skin had failed.—*London Med. ecord*, July 15, 1880.

Abscess near the Lower Eyelid of Dental Origin.

Dr. PARINAUD draws attention (*Archives Générales*, June, 1880) to this ocrrence, which he believes is by no means infrequent, although its origin is overoked. The summary of his paper is as follows: 1. Alterations in the temporry or permanent teeth may induce suppuration of the lower eyelid opposite the rbital border or in the region of the lachrymal sac, where it sometimes simulates chrymal tumour or fistula. 2. The course pursued by the pus, which originates an alveolo-dental periostitis, being intra-osseous, is difficult of detection, and not always in the same direction. 3. A variety of this periocular suppuration special to children of about five or six years old. The arrangement of the lveoli of the first and second dentitions explains this predisposition, and explains e occurrence of these suppurations, which may become complicated with necros of the orbital border. 4. In the adult, besides the cases of lachrymal tumour, properly so called, which may sometimes be attributable to a carious tooth, suppuration at the great angle of the eye may be observed under two conditions. Pus originating in an alveolus may penetrate into the maxillary sinus, induce inflammation there, and give rise consecutively to the formation of a cutaneous fistula at the inner angle of the eye. In another set of cases, probably much more frequent, the lachrymal passages are free, and the sinus is not implicated, and the connection is not visible which unites the abscess or the fistula to the dental alteration. Vascular canals, which open constantly by one or two orifices on the nasal process of the superior maxilla, and which communicate also with the foramina of the alveoli, explain the development of these suppurations. 5. In suppurations of the lower eyelid, in necrosis of the orbital border, and in suppurations or fistulæ at the larger angle of the eye, we should therefore ascertain whether the cause of the accidents observed is not a bad tooth, the extraction of which is the primary indication of treatment.—*Med. Times and Gazette*, July 17, 1880.

Treatment of Granulations in the Pharynx and Larynx by Ignipuncture.

Dr. KRISHABER (*Annales des Maladies de l'Oreille, du Larynx, etc.*, May, 1880) gives a description of glandular pharyngo-laryngitis—its causes, pathology, symptoms, diagnosis, and finally its treatment. The part of the larynx most commonly affected is the mucous membrane of the arytenoid cartilages. The author has, however, seen distinct granulations on the vocal cords without any concomitant implication of the remainder of the larynx, or of the pharyngeal mucous membrane. The granulations produced by hypertrophied glands may, if isolated, pass unnoticed during life, unless a very powerful illumination be employed. This, according to the author, explains how it is that some observers deny the presence of granulations in the larynx. They are almost always of larger size in the pharynx. When the granulations in the larynx attain to a considerable size, they form true polypi, having the structure of œdema. For destruction of the granulations, the author prefers the application of ignipuncture. When the granulations are situate in the pharynx, he uses for the purpose Paquelin's thermo-cautery, and when in the larynx the galvano-cautery. (The latter may, however, be used for both forms.) Three cases are cited, in which granulations in the larynx were treated by this method. In the first case, there were two large granulations in the anterior angle of the right vocal cord, one of which was removed by a single application of the cautery, the voice becoming perfectly clear. In the second case, both pharyngeal and laryngeal granulations were cauterized, with great improvement to the voice. In the third case, two large granulations, which produced no inconvenience, were accidentally discovered on the free margin of the epiglottis, and removed by a single application of the galvano-cautery. A fourth case is also described of a lady, suffering from pharyngo-laryngeal granulations, accompanied by a feeling of a foreign body in the throat, and a dry cough. Under treatment by ignipuncture, complete recovery ensued. The author considers that the danger in this method of treatment is much less than it seems; the normal laryngeal mucous membrane presenting a much greater resistance to cauterization than the morbid growths. The efficacy of this method is infinitely superior to that of other caustics. Of pharyngeal granulations treated by ignipuncture, the author has had more than forty cases. The number of applications required in these cases varies from five to twelve. In conclusion, the author states that this treatment of glandular pharyngo-laryngitis is almost painless, and is followed by no inconvenience, a result being very promptly obtained. It is easily applied, and, except in some rare cases, requires no special skill in its employment.—*London Med. Record*, July 15, 1880.

Examination of the Œsophagus under Chloroform.

The following is an abstract of a contribution by Dr. GIRARD, of Berne, to the *Centralblatt für Chirurgie*, No. 21, 1880. Under certain conditions, it is found necessary to give chloroform in order that a bougie may be passed readily down the œsophagus. In the administration of this anæsthetic, the usual sitting and the half-recumbent positions are inconvenient, and in the former position chloroform is dangerous, and the passing of a bougie during anæsthesia may be attended with much difficulty. This difficulty may be overcome by placing the patient on an operating table with the body lying horizontally and the head projecting beyond the table's edge, where it should be supported by an assistant, in order that the cervical vertebræ may not be bent too much over the edge, and made so prominent as to prevent the introduction of the œsophageal bougie. The surgeon stands on the left side of the patient, and is now able to introduce the sound under the following favourable conditions. 1. The mouth is either found open, or can be opened without any difficulty. 2. The trunk, neck, and head can be very readily fixed in the desirable position. 3. The buccal cavity, the pharynx, and the œsophagus are in a straight, or nearly straight line, and a straight instrument, if not too thick, can be easily passed. The surgeon, holding the bougie in the supinated hand, passes it in a horizontal direction, with a movement like to that of the first step of urethral catheterism. The supination of the surgeon's hand, and the horizontal movement, allow a freer, readier, and more delicate introduction of the bougie than does the movement in a vertical direction, and so favours a close exploration of any obstruction or stricture. Dr. Girard reports that he has practised this method in two cases with very satisfactory results. In one of these he had to deal with a carcinomatous stricture of the œsophagus, the coats of which were so sensitive that it was difficult to pass a bougie, save under chloroform. On the administration of this anæsthetic to the patient in the above described position, bougies of large size could be passed readily and precisely through the constricted portion of the canal. The second case was one of foreign body in the œsophagus. In conclusion, Dr. Girard suggests that it may be possible to apply his method to the introduction into the œsophagus of instruments permitting an endoscopic examination.—*London Med. Record*, July 15, 1880.

Foreign Bodies in the Air-passages.

The first case related by VOLTOLINI (*Monatssch. fur Ohrenheilkunde*, December, 1879) is that of a peasant, aged 27, into whose windpipe a needle, with a short thread attached to it, accidentally slipped. With the laryngoscope, the needle was seen to be sticking into the anterior wall of the trachea, not far above the bifurcation, and from the eye of the needle the black thread could be traced running across the trachea over the right true and false vocal cords to the arytenoid cartilage of the same side, the thread being continually blown to and fro by the current of air. Attempts to seize the thread with forceps were at first unsuccessful; subsequently, however, the author appears to have succeeded in loosening the needle with the forceps, and it, together with the thread, was coughed up. With the view of preventing in future cases a needle which has entered the trachea from falling down lower, the author has made some experiments, from which he finds that the application to the skin over the windpipe of an electro-magnet prevents the needle from falling down and retains it in contact with the tracheal wall. He also suggests withdrawing the needle through the glottis by means of a wire attached to the electro-magnet (and therefore itself magnetized); but in attempting to do so the needle would in all probability become detached by closure of the glottis, and so fall down into the trachea. In the second case, the ends of a pair of forceps had broken off and fallen into a patient's chest during an operation for laryngeal polypus. Violent cough ensued, which resulted after nine months in expulsion of the foreign body. The foreign body in this case was supposed to have passed into the stomach, but Voltolini suggests that an analysis of the sputum might have decided the question by showing the presence of iron, especially as the forceps was found to be much rusted. The patient recovered so completely, that auscultation and percussion indicated nothing abnormal. The author urges the necessity of care in preventing instruments used in the larynx from breaking off.—*London Med. Record*, July 15, 1880.

Foreign Bodies in the Œsophagus.

In a recent communication to the *Société de Chirurgie*, of Paris, of which a report is given in the *Gazette Médicale* of June 12th, M. LANNELONGUE stated that, during a service of three years and a half at the Sainte-Eugénie Hospital, he had extracted at least eighteen foreign bodies from the œsophagus in children. Of these bodies, thirteen were pieces of money, twelve having been sous and one a two-franc-piece. The other objects belonged to sets of toys and consisted of small plates, small bowls, portions of wheels from toy carriages, and, in one case, a small toy flask containing curaçoa. The ages of the patients varied from eighteen months to six years and a half. Children beyond the latter age are, as a rule, too sensible to swallow such articles as those mentioned. The young subjects of these accidents do not confess at once for fear of being scolded, and do not relate what has happened until the occurrence of disturbing symptoms. These symptoms usually consist in difficulty of deglutition and of pain and disturbance, often of reflex origin, in the movements of respiration and phonation. It generally happens that some time has passed between the introduction of the foreign body into the œsophagus and the application for surgical aid. In the first place, the surgeon should make sure that the foreign body has really been swallowed. He ought at once to explore the pharynx, not with the laryngoscope which the child would not tolerate, but with his finger. He should then proceed to examine the œsophagus with an olivary sound. This instrument, however, frequently deceives. After the foreign body has remained in the gullet for a short period it becomes coated with portions of food and with mucus, and so no rubbing noise can be heard on its contact with the olivary instrument. It is thought that the best instrument to introduce is the *panier à bascule* of Graefe, which consists of a small cage with two hooked appendages, the whole being fixed at one extremity of a curved rod. By means of this instrument the foreign body may be caught in one of the hooks and then withdrawn. In a brief analysis of his eighteen cases, M. Lannelongue stated that all the pieces of money were readily extracted by the use of Graefe's instrument. In one case serious hemorrhage followed the extraction of the foreign body, which was a small porcelain plate. In the case of a child, a little girl aged 6½, who had swallowed the toy flask of curaçoa, after the body had been felt with a sound and its position near the stomach made out, no attempt was made at extraction for fear of breakage. It was allowed to remain, and, on the third or fourth days, was discharged in pieces by the rectum. Instances of foreign body in the œsophagus of an adult are of rare occurrence. The author has seen two such cases. In one, the patient, a soldier, had swallowed an onion which, probably through its contact with fluids, had swollen so as to excite symptoms of commencing suffocation. M. Lannelongue, having no special instruments at hand, had recourse to a lithotrite. The male branch having been passed between the inferior part of the pharynx and the foreign body, the female branch was slipped lown on to the foreign body, which, after a lateral movement of the lithotrite, ras rejected by a violent effort on the part of the patient.—*Lond. Med. Record*, July 15, 1880.

—

Diagnosis of Tumours of the Mammary Gland.

Although the lines of demarcation between many of the tumours of the mamma re not very distinct, yet a careful attention to their more prominent signs enables ne to arrive at a pretty correct judgment as to their true nature. From an nalysis of the cases that have occurred in his own practice, and of those collated rom various sources, Dr. Samuel W. Gross has framed the following conclusions:—

1. A uniformly hard, perfectly movable, nodular, slowly growing tumour, paricularly if it be seated at the upper and outer part of the gland of impubic subects and of married women toward the twenty-third year, and be free from lceration, alterations in the skin, veins, nipple, and lymphatic glands, is a solid broma, and the diagnosis is strengthened by the presence of several growths in ne or both breasts.

2. A hard, lobulated, peripheral tumour, or one which, after having remained tationary or progressed slowly for several years, suddenly and rapidly acquires a rge volume, assumes an unequal consistence, being firm at some points and soft r fluctuating at others, occurring toward the thirty-sixth year, unaccompanied y lymphatic involvement, but attended, possibly, with discoloration of the kin, deformity of the nipple, and limited superficial adhesions, and, it may be, ith dilatation of the veins, discharge from the nipple, and ulceration and fungous rotrusion, is a cystic fibroma.

3. A firm, rapidly growing, peripheral tumor, appearing in prolific married males at about the thirty-seventh year, with, possibly, discoloration and adheon of the skin, and ulceration, but without deformity of, or discharge from, the pple, or enlargement of the glands, is a solid sarcoma. A tumour possessing ese attributes and occurring toward the thirty-second year is probably a firm indle-celled sarcoma, while one developing at about the forty-second year is ore apt to be a firm round-celled sarcoma.

4. A lobulated tumour, particularly if it involves the greater part of the mama, of quick growth from the commencement, or progressing rapidly after having creased comparatively slowly for some time, of large size, of varying or unequal nsistence, occurring toward the thirty-third year, in prolific married subjects, nd attended with discoloration of the skin, ulceration, enlargement of the veins, nd, possibly, with discharge from the nipple and limited adhesions, or, it may e, with deformity of the nipple and glandular enlargement, is a cystic sarcoma. A very rapidly progressing tumor, of soft, apparently fluctuating consistence, ith stretched skin and enlarged veins, appearing in young girls before puberty nd in young married women, is a medullary sarcoma, which may be solid or ystic, and is, as a rule, composed of small spindle cells.

5. A solitary, rapidly and continuously growing, although not very bulky, ather firm, or, possibly, soft tumor, occurring at about the forty-fifth year, with imited discoloration of the skin, but not fixed to the chest, and attended, possibly, with deformity of the nipple, superficial adhesions, ulceration, dilatation of the veins, and enlargement of the axillary glands, is a solid myxoma.

6. Cystic myxoma possesses the same consistence and growing attributes of the former variety, but it develops at about the forty-eighth year, and is liable to be attended with discoloration, adhesion, and ulceration of the skin. The veins, nipple, and glands, however, are normal.

7. A hard, heavy, nodular, solitary, very slowly and equably increasing

tumour, especially if it develops in the immediate vicinity of the nipple of a married woman toward the thirty-fifth year, and is accompanied by adhesion and discoloration of the skin, and ulceration, and, possibly, by deformity of the nipple and enlargement of the glands, but is free from fixation to the chest and dilatation of the veins, and is preceded by a discharge from the nipple, is a cystic adenoma. A solid adenoma cannot be distinguished from a solid fibroma.

8. A densely hard, inelastic, irregular, solitary, slowly growing tumour, occurring in prolific married females toward the forty-eighth year, inseparably connected with the mamma, accompanied by induration and enlargement of the associated lymphatic glands, retraction of the nipple, infiltration of, and, possibly, nodules in, the skin, ulceration, and fixation to the chest, and, it may be, by a discharge from the nipple, is a scirrhous carcinoma; and the diagnosis is strengthened if there be a history of heredity, if the tumour was preceded by psoriasis or eczema of the nipple, or if it be developed from an induration left by puerperal mastitis.

9. A soft, lobulated, voluminous, solitary, and rapidly increasing tumour occurring in the same class of women, at about the fiftieth year, and attended with infection of the glands and skin, retraction of the nipple, fixation to the chest, and, possibly, extension to the opposite breast, but without discharge from the nipple, or marked tendency to prominence of the veins or ulceration, is a medullary or encephaloid carcinoma.

10. A hard, very slowly growing, small, solitary tumour, occurring toward the forty-fifth year, with adhesion to the skin, and, it may be, nodules in that structure, prominence of the veins, retraction of the nipple, and enlargement of the glands, and, possibly, with invasion of the opposite breast, fixation to the chest, ulceration, and discharge from the nipple, is a colloid carcinoma.

11. A densely hard, irregular and knotty, contracting and small, solitary tumour, occurring at about the forty-seventh year, and attended with retraction of the nipple, infection of the glands and skin, and, possibly, distinct tubers in the latter structure, ulceration, and immobility on the chest, is an atrophying scirrhus.

12. A slowly increasing, solitary, nodular, or slightly lobular tumour, occurring after the menopause, covered by thinned and discoloured skin, fluctuating, and, probably, discharging by the nipple, but without enlargement of the veins or glands, and without fixation to the chest, is an involution cyst.

13. A solitary, smooth, firm and elastic, or, possibly, fluctuating tumour occurring in the vicinity of the nipple of young and prolific married women. Of moderate volume, of slow growth, and unattended with alterations in the veins, nipple, skin, or glands, or with adhesions, but liable to ulceration and enlargement of the glands if it inflames, is an evolution cyst.

14. A solitary, slowly growing, not bulky, fluctuating, or semisolid tumour occurring near the nipple of lactating women, and unattended with changes in the coverings of the mamma or in the glands, is a lacteal cyst.

15. A slowly growing, small, smooth, round, firm, and elastic, or fluctuating, solitary tumour, occurring between the ages of twenty and thirty years, seated at the upper and outer border of the breast, and not near the mammilla, with a disposition to ulcerate, but without other changes in the skin, veins, or glands, is an hydatid cyst.—*New York Med. Journal*, June, 1880.

Paracentesis of the Pericardium.

Dr. P. KUMMELL, of Berlin, in a contribution on the subject of paracentesis pericardii (*Berliner Klinische Wochenschrift*, No 23, 1880) states that this operation is very seldom indicated. Of 12,837 patients admitted into the Allgemeine

Krankenhaus of Berlin during the past five years, there were but thirty-eight affected with pericarditis. In eight of these cases there was considerable effusion of fluid into the pericardial sac, but in two only of these instances was it thought necessary to have recourse to tapping. The subject of the first case was a male, aged 22, who, in the course of a second attack of acute rheumatism, suffered from acute fibrinous pericarditis, resulting in considerable pericardial effusion. For the relief of extreme and threatening dyspnœa, the fourth intercostal space was punctured by a needle attached to an aspirating syringe, and about two ounces of blood-stained serous fluid removed. The results of this operation were most satisfactory: the dyspnœa ceased almost immediately; there was no renewal of the effusion, and the patient made a speedy and complete recovery. The second case was one of considerable effusion into the pericardial and left pleural sacs of an emaciated and anæmic man, aged 50, whose general health had previously been very good. In consequence of increasing dyspnœa with cyanosis, the pericardial sac was tapped on the sixth day of treatment, and thirteen ounces and a half of clear serous fluid were withdrawn. At the same time, twelve ounces of fluid were removed from the left pleural cavity. The tapping gave much temporary relief, and was followed by diminished intensity of the dyspnœa and cyanosis, but two days later it was found necessary to repeat the operation. Fifteen ounces of slightly blood-stained serous fluid was removed, but again with only temporary relief. There was rapid re-accumulation of the fluid, and the patient died on the fourth day after the date of the second operation. The post-mortem examination revealed deposit of gray tubercle in the serous layer of the pericardium, recent pericarditis, enormous distension of the walls of the sac, and accumulation within the sac of about thirty ounces of blood-stained fluid containing soft fibrinous flakes. The puncture in the second case had healed, and no traces of any inflammatory reaction could be observed along the course of the needle. About three-quarters of an inch above the line of puncture, there was found an adhesion of the parietal to the visceral layer of the pericardium, of the extent of a thaler piece. Had the needle been introduced at this part it would probably have passed into the muscular structure of the heart, and no serous fluid would have been drawn off. Adhesions of this kind are usually of limited extent in front of the heart. In order to guard against error or danger, it is recommended that one, or, if necessary, more preliminary punctures be made with the small needle of a Pravaz's syringe. A fine and well-tempered needle may be introduced at any point without danger, even if it pass into the wall of the heart or into one of its cavities. The puncture should be made at a distance of about two inches from the left margin of the sternum, and in one of the spaces between the cartilages of the fourth and seventh ribs. The puncture, Kummell states, is best made with a hollow needle attached to an aspirating syringe, the diameter being about one-twelfth of an inch. This method of operation is advocated as one that can be most easily practised and is attended with least danger. It is applicable to most of the cases in which paracentesis pericardii is indicated, and it can be conveniently repeated at short intervals. It remains to be proved by future experience whether equally good results can be obtained by dissecting down to the pericardium under antiseptic conditions.—*London Med. Record*, July 15, 1880.

Modification of Lee's Operation for the Radical Cure of Varicocele.

Prof. **James M. Holloway**, of Louisville, finds (*Medical Herald*, August, 1880) that between the upper and lower needles, where the subcutaneous division of the veins is to be done, the structures have to be stretched by an assistant in order that the enlarged veins may be tightened, as tendons are put on the stretch in the operation for talipes; otherwise the sharpest knife will hardly sever the veins.

They are enlarged, tough, and very elastic, as is shown by their variable aspect when empty or full. And this is the cause of the difficulty in doing the operation as directed by Mr. Lee. The veins are more elastic than the fascia and skin; consequently, when the assistant has separated the needles to the utmost, the skin is tense and the fascia seems to be so; but the elastic, tortuous, empty veins move freely away from the sharp edge of the knife, and when finally imprisoned between the blade and the stretched integument, are only partially severed if at all. Any force exercised at this stage of the operation is likely to drive the sharp edge through all the structures, and thus defeat the effort to do a subcutaneous section. Having failed to accomplish a cure in several cases by a patient effort to do the operation as Mr. Lee directs, Dr. Holloway adopted the plan of enlarging slightly the orifice in the skin and fascia made by the tenotome; then, by carefully lifting each vein upon the edge of the knife, he draws it to and causes it to emerge slightly through this orifice, and then its section becomes not only easy but demonstrable. After the veins are divided, one suture is sufficient to close the incision and make it in all respects a subcutaneous wound.

Essence of Winter-green in the Treatment of Purulent Cystitis, etc.

M. PERIER has treated a patient suffering from purulent cystitis by washing the bladder out with an antiseptic substance, hitherto more employed by perfumers than by chemists, the essence of winter-green (*Journal de Médecine et de Chirurgie*, May, 1880). It is a powerful antiseptic with a penetrating and rather pleasant odour, not at all of an irritating character. Unfortunately, it is but little used. Its somewhat high price would be no obstacle to its use, because it is only employed in small doses. The essence of winter-green is obtained from the *gaultheria procumbens*, a shrub which grows in North America. This essence is known chemically as salicylate of methylene or salicylic methylether. It is not soluble in water, and some difficulty is experienced in dissolving even small quantities of it. M. Perier has often had recourse to the following solution: Essence of winter-green, 6 grammes; tincture of quillaya saponaria, 30 grammes; water, 1 litre. He uses this solution freely for washing out the bladder, with excellent results, and without causing the least irritation. It constitutes an excellent fluid for the washing of wounds and for simple dressings. M. Perier likewise combines winter-green with vaseline, so as to make an antiseptic and inodorous ointment. He uses the following proportions: Essence of winter-green, 1 gramme; vaseline, 100 grammes. He greases his sounds and specula with it, and also uses it to anoint his fingers and hand, for examination by touch. Even in the practice of antiseptic surgery, M. Perier frequently covers his hands with this antiseptic vaseline instead of washing them too often with carbolic acid and water.—*London Med. Record*, June 15, 1880.

A Difficult Case of Stone in the Bladder.

At a recent meeting of the Imperial Medical Society of Vienna, Professor DITTEL related the following case. A merchant, aged 48, had for ten years suffered from disease of the bladder, and for four months had had symptoms of stone. Having ascertained the presence of a calculus, Dr. Dittel performed lithotrity twice. A quantity of detritus, consisting of phosphate and oxalate of lime, was removed; but the principal mass of the stone resisted crushing, and Dr. Dittel suspected that it was sacculated. He directed an assistant to introduce his finger into the rectum and push the stone forward; but still he was unable to seize it. As a result of the lithotrity, a large number of fragments of stone came away; but one remained so firmly fixed in the fossa navicularis, that urethrotomy was necessary for its removal. After four days, a similar accident occurred, and the wound had to be reopened to remove the fragment of stone. On May 2d, Dr. Dittel performed lateral lithotomy. On introducing his finger into the bladder, he reached the diverticulum, but found that the stone was so closely grasped by it that, after trying for an hour, he found it quite impossible to pass his finger between the calculus and the wall of the sac. He therefore decided to perform the high operation, but was still unable to dilate the diverticulum with the finger. He then introduced a scoop between the wall of the diverticulum and the stone, and endeavoured, until he became wearied, to raise the calculus from its bed; an assistant then continued the attempt, using the symphysis pubis as a fulcrum, and applying leverage with all his force until the handle of the scoop was bent. After these attempts had been carried on for an hour and a half, the stone was at last broken up and removed in fragments. Considering the severe handling which the parts had undergone, the most unfavourable result was naturally expected, especially as parenchymatous hemorrhage from the wound set in some hours after the operation, rendering it necessary to plug the rectum. The patient became collapsed, and nausea, vomiting, and other symptoms of peritoneal irritation appeared. The case, however, ran a favourable course. Fourteen days after the operation, the patient was free from fever, and the wounds were perfectly clean.—*British Med. Journal*, June 26, 1880.

On a New Method of Arresting Gonorrhœa.

Under this title Mr. W. Watson Cheyne, Assistant Surgeon to King's College Hospital, describes (*British Med. Journal*, July 24, 1880) an antiseptic treatment of gonorrhœa. An examination of gonorrhœal pus disclosed the presence of micrococci in large numbers, and Mr. Cheyne thinks it probable that the essence of the disease consists in the growth of these or allied organisms.

In the case of gonorrhœa, Mr. Cheyne supposes that, at the time of infection, a small number of the specific organisms, which in all probability possess a considerable resisting power to the destroying action of the healthy living tissues, are retained in the urethra, that these go on developing, that the products of their growth irritate and weaken the mucous membrane in their vicinity, that the organisms can then penetrate into and live in that weakened tissue, and that the extension of this process over a portion of the mucous membrane of the urethra is the cause of the inflammatory symptoms.

Now, granting that this view, Mr. Cheyne says, which I think must be admitted to be very probable, were proved, the problem to be solved for the cure of gonorrhœa would be, how to destroy these organisms without at the same time injuring the inflamed and highly sensitive mucous membrane. If they were destroyed, one would expect the extension of the disease to cease, and the inflamed mucous membrane to return more or less rapidly to a normal state. On thinking this matter over, two substances appeared to me suitable for this purpose, being both powerfully antiseptic, and at the same time but little irritating. These are iodoform and oil of eucalyptus.

The next question was, how to apply them. It is quite clear that, if used as an injection, there would be no certainty that they would be brought into contact with the whole of the inflamed surface, partly because the swollen mucous membrane would interfere with the passage of the fluid, and partly because the patient would not in many cases apply it effectually. At the same time, an injection could not be expected to do much good, for it would flow out very quickly, and the antiseptic would not have sufficient time to act. I therefore use these antiseptics mixed with cacoa butter, and made into bougies of various lengths. These bougies are introduced well into the urethra, and a strap and pad over and around the orifice retain them. The bougie rapidly melts, and the mucous membrane of the urethra remains bathed in the antiseptic material for any length of time desired. These bougies possess an additional advantage over injections in that, from their size (they have a diameter of a No. 9 or 10 catheter, tapering at the point), they, so to speak, unfold the swollen mucous membrane, and thus cause the antiseptic to be more thoroughly applied.

I have tried the two antiseptics separately and also combined, and I find that they are most effectual when used in combination (possibly because iodoform is soluble to a considerable extent in oil of eucalyptus, and is thus brought into more perfect contact with the mucous membrane). The formula which seems best is five grains of iodoform[1] and ten minims of oil of eucalyptus in a bougie of forty grains. These bougies have been made for me by Mr. Martindale, of New Cavendish Street.

The specific cause of the disease being eradicated by this means, the question of further treatment arises. It seems to me that, although the development o the gonorrhœa is arrested, yet, if the discharge be allowed to become septic an irritating, urethritis might be kept up for some time. I, therefore, order a injection of boracic lotion (saturated aqueous solution of boracic acid), or a emulsion of eucalyptus oil (one ounce of eucalyptus oil, one ounce of gum acaci water to forty or twenty ounces) to be used for two or three days. At the en of that time, injections of sulphate of zinc, two grains to the ounce, may be begun. At the same time, the great tendency of the urethral mucous membrane, when once inflamed, to remain in a state of inflammation, must be kept in mind, and everything which might tend to keep up the inflamed state must be removed. Notably, the patient must be cautioned against drinking, and it is well to orde diluents and alkalies.

The method may be summed up as follows. The patient is first told to emp his bladder, partly to clear out his urethra, and partly to prevent the necessi of expelling the antiseptic from the canal for several hours. He then lies do on his back, and a bougie from four to six inches long is introduced. and th orifice of the urethra closed by strapping. The bougie ought to be dipped i eucalyptus oil, or in carbolic oil (1–20) before insertion. The patient is instructed to refrain from passing water, if possible, for the next four or five hours. If the case be severe and advanced, he takes another bougie home, and is instructed to introduce it in the same manner after he next passes urine. On th evening, or on the following day, he commences the antiseptic injection, which he uses four or five times daily. On the third or fourth day, when the symptoms have entirely subsided, an injection of sulphate of zinc, two grains to the ounce, is begun.[2] At the same time, the other points mentioned are attended to.

I have now used this method in about forty cases, and in all the result has been the arrest of the progress of the gonorrhœa. For a day or two the purulent discharge continues; but afterwards it steadily diminishes in amount, becoming in four or five days mucous, and ceasing altogether in a week or ten days. At the same time, the scalding and pain and the symptoms of inflammation rapidly diminish, and disappear completely in about thirty-six to forty-eight hours. In fact, the case becomes no longer one of virulent gonorrhœa, but one of simple urethritis, rapidly progressing towards recovery, if properly treated.[1]

---

[1] A considerable number of the cases have been treated with bougies containing ten grains of iodoform; but Mr. Martindale informs me that during the warm weather it is almost impossible to make them. I find, however, that bougies containing five grains are quite satisfactory, and I have had no symptoms of irritation following their use.

[2] In hospital practice, where the patient is only seen once a week, and where there is no great necessity for arresting the discharge quickly, I do not order the sulphate of zinc injection till the week following the introduction of the bougies.

I have used this treatment only in the early stages of the disease, from the first to the seventh day after the commencement of the symptoms; but it has answered equally well in all. Thus the following is the case in which it was used seven days after the commencement of the symptoms. The patient presented himself on June 19th, stating that the symptoms of gonorrhœa had existed for seven days. There was a profuse purulent discharge from the urethra; the penis was somewhat swollen and red; there was intense scalding when urine was passed, and a constant feeling of heat and uneasiness; no chordee. A bougie, containing ten grains of iodoform and ten minims of eucalyptus oil, was passed down, and the orifice closed in the usual manner. The patient was also ordered an injection of an ounce of oil of eucalyptus and an ounce of gum acacia in a pint of water, to be commenced in the evening, and to be used four or five times daily. On the 19th, he again presented himself, and stated that he had not passed water till five hours after the introduction of the bougie; that the scalding and feeling of uneasiness rapidly subsided, and had completely ceased in forty-eight hours; and that the discharge had steadily decreased from the second day, and was now very small in quantity. He was ordered the sulphate of zinc injection, which completed the cure in three days.

In one case, there was a recurrence of the symptoms. The patient, a hospital patient, first presented himself on June 5th, stating that on June 2d, five days after connection, a discharge had commenced, which had steadily increased, and was now profuse and accompanied with considerable uneasiness and scalding in passing urine. A bougie containing ten minims of oil of eucalyptus alone was inserted; no other treatment was ordered. On June 9th, he returned, stating that, after the introduction of the bougie, the scalding and uneasiness had diminished, and had almost disappeared on the evening of the 6th; but that on the afternoon of the 7th they began to return, and were now more severe than on the 5th. I introduced a bougie containing ten grains of iodoform and ten minims of eucalyptus oil, and gave the patient another to insert at bedtime. At the same time, I ordered the injection of boracic lotion to be commenced on the following day. When seen again on the 16th, he stated that this time the treatment had been successful, and that now the discharge was very slight. An injection of sulphate of zinc and a mixture containing copaiba were ordered, and the discharge ceased entirely on the 20th.

In two or three cases, there has been slight increase in the scalding on the first or second occasion on which the patient passed urine after the introduction of the bougies; but this has only been temporary, and these cases were as rapid as the others. In four instances, however, there has been considerable increase in the symptoms for twenty-four or thirty-six hours. In three of these, the bougies had been made with beeswax; and they did not melt properly, and consequently came out of the urethra at various periods as small cakes. Further, it seems that some iodine had been set free from the iodoform, probably during their manufacture. In the fourth case, four bougies, each containing 10 grains of iodoform, were introduced in succession. In all these, however, the symptoms passed off in about three days; and then the gonorrhœa was found to be checked, just as in the other instances.

---

[1] The course described here is that usually followed when boracic lotion has been employed as the injection; but since I have begun the use of the eucalyptus emulsion, the cessation of the discharge has, as a rule, been more rapid. Thus, to give an example, a patient came to the hospital on July 3d with symptoms of gonorrhœa, which had lasted four days. He was suffering from a very acute attack, having severe scalding and commencing chordee. He had not previously suffered from gonorrhœa. A bougie containing five grains of iodoform and ten minims of eucalyptus oil was introduced; and he was ordered to begin an injection of the eucalyptus emulsion (1 in 40) in the evening. The patient showed himself again on July 7th, and stated that in twenty-four hours the painful symptoms had entirely disappeared, and that the discharge diminished rapidly, and ceased altogether on July 6th. I have since that time had several nearly as rapid cases. I have tried in three cases injections of eucalyptus emulsion without previous introduction of a bougie, but without any appreciable effect on the progress of the disease.

Such are the results as yet obtained by this method. I do not claim any specific power for the two substances I have mentioned. It may be that there are other antiseptics which would be more suitable, and I intend to test any which seem likely to yield good results. Whatever substance be used, however, I venture to think that the results already obtained show that the principle on which it ought to be applied, and on which it will prove most satisfactory, is that which I have attempted to indicate in this paper.

On Chancre of the Meatus and Urethra in the Male.

In an interesting discussion of this lesion Dr. J. NEVINS HYDE, Professor of Skin and Venereal Diseases in Rush Medical College, Chicago, presents the following conclusions:—

1. Chancres of the meatus and of the urethra are symptomatically distinct.

2. Chancres of the meatus are chiefly remarkable for their irritability, in consequence of the passage over them of the urinary current, their tendency to phagedena, and the characteristic deformity of the glans which they frequently occasion.

3. Intra-urethral chancre, as distinguished from visible chancre of the meatus and chancre involving in part only the rim of the urethral valve, is of exceedingly rare occurrence.

4. Intra-urethral chancre, invisible or but imperfectly visible to the eye unaided by the endoscope, can usually be distinguished as such in consequence of the mass of induration which lies immediately beneath the urethral mucous membrane at the site of the lesion, and is readily recognized by the touch through the external tissues of the male organ.

5. Intra-urethral chancres are accompanied by very scanty or insignificant discharge, and when the latter is present, it bears no proportion to the evident signs of disease connected with the sclerosis.

6. The reddened furrow or sulcus, covered with a thin secretion, visible in the floor of the fossa navicularis, especially in the subjects of gleet, should never be mistaken for intra-urethral chancre.

7. When a man exhibits a decidedly purulent urethral discharge, without coincident symptoms of unmistakable syphilis, he can be safely pronounced free from all danger of the last named disease, provided always the period of incubation of syphilitic chancre has, in his history, already lapsed.

8. Intra-urethral chancre need therefore never be mistaken for gonorrhœal disease, as the two affections are so distinct that a differential diagnosis can usually be satisfactorily established without the aid of the endoscope.

9. For many reasons the endoscope should be regarded as a valuable adjuvant in the diagnosis of urethral disorders, and recourse should be had to it in all doubtful cases.—*Chicago Medical Journal*, Aug. 1880.

Digital Compression of Aneurisms.

Dr. PIZE (*Bulletin de Thérapeutique*, April 30, 1880) condemns the teaching of Bellingham and Broca, to the effect that total compression gives rise to the formation of soft or passive clots in an aneurism, while partial compression favours the formation of solid fibrinous clots, which alone conduce to repair. The author advocates the retention of digital compression during the first twenty-four or forty-eight hours, after which it should be intermitted at night, to allow the patient to sleep. He considers that total digital compression offers advantages over any other means of treatment, inasmuch as (1) it is not dangerous; (2) it is more rapid in its action; (3) it is more often successful, and gives more brilliant results; (4) it has succeeded in cases in which partial compression has failed. He says that the reason why this treatment is most successful is because it most conduces to coagulation of blood within the aneurismal sac.—*London Med. Record*, July 15, 1880.

Bony Tumour in Muscle.

In the *Presse Méd. Belge* Dr. THIRIAR relates the case of a sawyer, thirty-six years old, whose foot slipped while playing at skittles, he at the time having in his hand a bowl weighing between twenty and thirty kilos. He felt a violent pain opposite the insertion of the adductor longus in the pubis. Next day he felt in this locality a tumour the size of a pea, which gradually enlarged in all directions. At first it caused neither pain nor inconvenience; but, after a while, pains came on, and motion became first difficult and then impossible. When Dr. Thiriar first saw the patient, some weeks after the accident, he found a hard conical tumour, five centimetres in length, extending from the pubis into the adductor. Its removal was accomplished between two and three months after the accident, the adhesion to the pubis being so strong as to require the use of a forceps. It was found to be a true osteoma composed of spongy bony tissue. It was supposed to have originated in the portion of the adductor attached to the pubis, and gradually invading the muscular tissue. Recovery from the operation was complete three months after the occurrence of the accident.—*Med. Times and Gazette*, July 31, 1880.

Case of Osteomyelitis.

Professor KÖNIG of Gottingen has reported (*Centralblatt für Chirurgie*, No. 14, 1880) the following case of recovery after amputation for suppurative osteomyelitis of the femur. The patient, a labourer, aged 39, had been laid up about eight years previously with suppurative inflammation of the left knee due to an injury to this joint. The man at that time had made a good recovery, and for the subsequent five years had been able to make full use of the affected limb. At the end of this period, however, the left knee had again become swollen without any evident cause. When the case was first seen by Professor König, the left lower limb was almost quite useless; the leg was semi-flexed, and there was a slight outward bending at the knee. The tibia had been dragged backwards, and the movements of the knee were restricted to slight flexion which caused much pain. It was thought necessary to excise the diseased knee. As in every instance of this condition of joint-flexion, abduction with much backward displacement of the tibia; the operation was attended with great difficulty, in consequence of contraction and shortening of the soft parts at the back of the limb. The wound remained aseptic for eight days, but subsequently, without any recognizable cause, suppuration came on, which increased, and was associated with fever, rising at times, and very irregularly, to 104 deg. Several incisions were made, but without good results, and it soon became evident that suppuration had extended along the shaft of the femur, and that the patient, pallid, and without appetite, was suffering from severe septic poisoning. Six weeks later the affected limb was amputated at the middle of the thigh. In the division of the bone the saw passed through a large collection within the medullary cavity of putrid pus. Professor König hesitated, on account of the prostrate condition of the patient, to remove the limb at the hip, and made an attempt to save the remaining portion of the thigh by treating antiseptically the purulent osteomyelitis. By means of a sharp spoon mounted on a long handle, all the putrid and degenerated marrow was removed from the medullary cavity. This cavity was next cleansed by the introduction of plugs of cotton-wool impregnated with a concentrated solution of chloride of zinc until all bad smell was removed. The surfaces of the flaps having been washed with the solution of chloride of zinc, the wound was closed by sutures and drained, and finally covered by antiseptic dressings. A long drainage-tube was also inserted into the medullary canal. The dressings were renewed daily, and the medullary cavity washed out with a solution of carbolic acid injected through the drainage-tube. On the fifth day, as the discharge had a bad smell, the stump was laid open, and the surfaces of the flaps were again disinfected. The stump subsequently healed by granulation, and without any putrefaction of the discharge. The amputation was followed by a fall of the patient's temperature, and by much improvement in his general condition. In his remarks on this case, Professor König states that it is doubtful whether the suppurative osteo-myelitis was the result of a fresh infection after resection of the knee, or was due to a pre-existent osteomyelitic deposit. The latter view was formed by the existence made out at the time of the amputation of considerable persisted thickening along the femur. The case is regarded of some importance, as it proves the possibility of dealing successfully with acute putrid osteomyelitis—a much and justly-dreaded result of injury of bone—by removal of the suppurating medulla, and disinfective cleansing of the medullary canal with a concentrated solution of chloride of zinc.—*London Med. Record*, June 15, 1880.

Relapsing Luxation of the Humerus.

According to Roser, repeated luxation of the head of the humerus is due to enlargement of the communicating orifice between the shoulder-joint and the bursa of the subscapularis muscle. Malgaigne, on the other hand, held that it was the result of premature movements of the joints after the original injury, and of consequent incomplete cicatrization of the rent in the capsular ligament. Dr. JOESSEL, of Strasburg, states (*Deutsche Zeitschrift für Chirurgie*, Band xiii. Heft 2) that there is no anatomical evidence in favour of either of these views, and he describes nine preparations, four from subjects, who, as had been well known, had suffered from repeated dislocation of the shoulder during life. These specimens show, in the author's opinion, that the predisposition to relapse of the luxation is the result in some instances of extreme distension of the capsule, but in most of permanent separation of the tendons of the muscles inserted into the tuberosities of the humerus, which tendons, in most cases of luxation of the head of the bone, are torn away at their attachments. In some very rare cases, relapsing luxation at the shoulder is the result of fracture of the glenoid cavity or of the head of the humerus.—*London Med. Record*, July 15, 1880.

Midwifery and Gynæcology.

Intractable Vomiting of Pregnancy treated by the Inhalation of Oxygen.

Dr. **Pinard** relates (*Annales de Gynécologie*, Mai, 1880) the case of a patient, aged twenty-two, pregnant for the first time. Vomiting began in the first month, and continued with great severity, all food being returned, and the patient in consequence becoming very weak and emaciated. Ipecacuanha, citrate of magnesia, ether spray, hypodermic injections of morphia, were all tried without any effect. After the vomiting had lasted about seven weeks, the inhalation of oxygen by the Limouzin apparatus was tried. The first day of this treatment ten litres were inhaled, the second day twelve litres, and fifteen litres the third. From this time the vomiting ceased, and no more treatment was necessary. The patient rapidly recovered her health, and went to the full term of pregnancy. It should be added, that in the early part of pregnancy, the uterus was retroverted, and, Dr. Pinard remarks, many authors would look upon this as the cause of vomiting. But the retroversion was spontaneously reduced before the oxygen was resorted to, and the vomiting continued as before. The association therefore of the vomiting with retroversion was here nothing more than a coincidence. Dr. Pinard was led to prescribe the oxygen inhalation by the facts made known by Professor Hayem, showing the beneficial effect of oxygen inhalation in the vomiting of chlorotic patients. Whether in this case the vomiting ceased spontaneously, or in consequence of the oxygen, the author points out, the future only can show; and he hopes that others will use the remedy, and publish their results.—*Obstetrical Journal of Great Britain*, July, 1880.

Amputation of the Procident Arm for the purpose of facilitating Version.

Dr. **Pénard** (of Rochefort) writes on this subject, and to his paper is added a postscript by Dr. Pinard, of Paris. The authors refer to the statements on this subject in systematic treatises on midwifery, and though fully agreeing that such a proceeding should never be thought of while there is the least spark of life to be perceived in the child, yet, considered in relation to cases in which the child has been long dead, he thinks it has been unjustly condemned. He considers that there are cases in which version is impracticable, and where embryotomy seems called for, and yet in which, after the procident arm has been removed, turning can be performed; that therefore, in such cases, amputation of the arm may be looked upon as a substitute for embryotomy. Dr. Pinard adds a theoretical explanation of the view which Dr. Pénard's experience has led him to form. He supposes that there are cases in which, if the scapular projection is entire, the superior border of the shoulder may become fixed against the lower border, or the posterior surface, of the symphysis pubis. In such cases, if, by amputation of the arm, the projection of the shoulder is destroyed, the trunk will readily rise, and the lower extremity can be brought down. He states that he has known many times MM. Pajot and Stoltz perform version in cases in which it was previously thought impossible, after simply amputating the upper extremity.—*Obstetrical Journal of Great Britain*, July, 1880, from *Annales de Gynécologie*, Dec. 1879.

Treatment of Post-Partum Hemorrhage.

Dr. **George J. Engelmann**, of St. Louis, thus briefly outlines (*St. Louis Med. and Surg. Journal*, Aug. 1880) that treatment of post-partum hemorrhage, which seems to him the most rational, as suggested by his own experience, and a careful analysis of the recent experience of able and judicious obstetricians.

A.—*Preventive treatment after induction of labour.*—1. Careful attention to every detail, and strict observance of obstetric rules in *every* case of labour.

2. The administration of a full dose of ergot as the head enters the vaginal orifice.

3. Should hemorrhage threaten, follow the uterine fundus with the firmly superimposed hand.

4. Express the placenta by Crêdé's method, and retain a firm grasp upon the fundus.

B.—*Treatment of an existing hemorrhage.*—1. External manipulation, pressure, and friction with the cold hand, or with ice.

2. Ergot—best subcutaneously, one or two large doses, whilst other manipulations are in progress.

3. Introduction of the hand into the vagina, and if no contractions follow, into the uterus; removal of clots and irritation of the surface, in order to stimulate contractions.

4. The subcutaneous administration of ether.

4*a*. Ice or vinegar, if at hand, may now be tried in the uterine cavity, but if they fail must not be persisted in.

5. The hot-water douche, which, if it is not followed by the desired contraction, will at least stimulate the patient, and cleanse the cavity, so that the final, safest, and most reliable remedy may be resorted to.

6. The iron swab—this may be used at once, if the introduction of the hand and the subcutaneous injection of ether fail, or after the trial of the hot-water douche; but in desperate cases must be resorted to at once, without losing time with other less reliable methods.

Puerperal Fever at Queen Charlotte's Hospital.

The annual report of Queen Charlotte's lying-in Hospital for 1879, contains an interesting account of an outbreak of puerperal fever in that institution. It appears that a severe outbreak of puerperal fever occurred in the hospital in the spring of 1879, necessitating the closure of the hospital from April 21st to September 20th of that year. Careful investigation failed to show that either overcrowding, defective sanitation, or ventilation, had any influence in the production of the fever. The midwives were attending their private cases in the district with impunity, nor was there a single case of fever in the out-patient department of the hospital, nor, so far as could be ascertained, in the district, during the whole time of the outbreak. On April 10th, the porter was stricken down with erysipelas, of which he almost died in the Westminster Hospital. On questioning him about his illness, it was elicited that, upon the removal of certain batches of linen from the disinfecting apparatus, for some time past he had felt ill, with violent headache, sore-throat, and sickness. This circumstance directed attention to the linen as a possible factor in the spread of the disease, and, on inquiry being made in this direction, it was found that the temperature in the disinfecting apparatus could be raised only to 180°, 70° below the proper standard. It also transpired that the porter did not know how to work the apparatus, and that his predecessor had been equally ignorant. Consequently, from October, 1878, to April, 1879, the apparatus was practically useless for the purpose of disinfection. It is here noted in the report that it was no part of the house-surgeon's duty to attend to the disinfection of the linen. Thus the disinfectant stove became a propagator of disease, as the linen was kept for several hours in a close, moist, warm atmosphere, and the bulk of the linen came out of the stove feeling damper than when it was put in. In this condition it was sent upstairs, and, frequently without being aired, distributed to the patients. The linen, when it came from the laundress, was too damp to be disinfected. This arose from the shortness of the supply not allowing a sufficient time for drying and airing, and from a mistaken notion on the part of the laundress that the disinfecting apparatus was a drying stove. The outbreak of fever finally culminated in the deaths of no fewer than seven women out of twelve patients delivered in the hospital from March 27th to 29th, of whom ten came in within twenty-six hours. Extended investigation also revealed the following facts, which, coupled with the above, led to the conclusion that the fever was conveyed by, and probably originated in the linen.

1. The periodical outbreaks of fever, as far as could be ascertained, appeared to correspond with the returns of certain batches of linen from the wash.
2. Mothers and infants supplied with brand new linen did perfectly well.
3. Women who were doing well suddenly developed marked feverish symptoms, which corresponded with the change of linen.
4. Cases suffering from puerperal fever, and convalescing most favorably, appeared to be restricken; and this occurred more than once in the same patient. Some of these cases recovered, and some died. This necessitated latterly the use of brand new linen for infected cases, in order to give them a chance of recovery.
5. Infants were attacked with local erysipelas (nates et genitalia) after the application of certain linen which had been used by infected mothers.
6. None of the nurses who slept in the wards with their patients were affected. The linen supplied to them was household linen, and was not used by the patients.

In the course of the investigation, several circumstances were brought to light which probably had some bearing on the outbreak and spread of the disease.

1. Certain articles of linen were used by mothers and infants alike.
2. The linen had been habitually distributed damp and unaired, particularly on one floor, during the last six months.
3. That injunctions from the medical officers to return for stoving all linen sent up from the stove damp, were disregarded.
4. Infected and uninfected linen were sent to one and the same laundress.
5. The linen in use in the labor wards was the same as that used by the patients generally.
6. There was no inventory made of the linen before it was sent to the wash, only on its return.
7. For several months, the soiled linen from the labour-wards was mixed with the impure linen from the lying in wards, and was kept together in closed cans for many hours. The labour-ward linen became so "heated through fermentation, that it could hardly be touched." It is believed that this, amongst other things, was a most important element in the spread of the disease.
8. Disinfection with the ordinary disinfectants, even boiling and prolonged baking at a temperature of above 250°, do not destroy the germs of mischief in linen highly charged with septic impurities. This fact has been more than once observed by the medical officers. Each baking and boiling, it is true, they say, lessens the virulency of the poison, the attacks caused by it become milder, but still some germs of mischief remain. This was remarkably the case on the reopening of the hospital in 1877, after the outbreak of fever in 1876. Although the hospital had been closed for three months, nearly every patient admitted on its reopening was stricken with feverish symptoms, and erysipelas soon showed itself. The number of admissions kept on increasing, the patients attacked be-

came fewer, and the type of the disease milder, until it finally disappeared. During this time, the greatest care was taken to have the linen properly stoved, and the apparatus was in perfect working order. A consideration of these facts renders it surprising that the outbreak did not occur earlier. The precautions taken since the reopening of the hospital in September, 1879, have hitherto had the happiest results, every patient being treated on antiseptic principles.—*Brit. Med. Journal*, July 31, 1880.

Acidity as a Cause af Sterility.

In the *Bulletin de Thérapeutique*, June 15, Dr. **Charrier** publishes a paper which he read at the Paris Socié:é de Médecine; it terminates with the following conclusions: 1. In some rare cases, in women who are otherwise quite well, the utero-vaginal secretions are quite sour, as is seen by their reddening litmus. 2. This acid may prove an absolute obstacle to fertility, as spermatozoa are killed in even a slightly acid medium. 3. This abnormal state is to be remedied by an alkaline treatment, by means of alkaline drinks and baths, and tepid alkaline injections. 4. When this acid condition has been neutralized, conception may take place. (Two cases in point are detailed.) 5. This disappearance of acidity under the influence of alkaline treatment may explain the success which is obtained at alkaline and sulphuro-alkaline mineral water establishments in the treatment of sterility. In a note in the *Bulletin* of June 30, Prof. Pajot entirely confirms this statement, and says that for many years past he has been in the habit of prescribing injections of Vichy water in these cases of acid vaginal discharges. He observes that in fair women, and especially those with a red complexion, and more rarely in brunettes, the acidity of the secretions sometimes reaches such a point, that, in spite of the extremest cleanliness, the acid odour is perceived during the passage of the speculum. Dr. Charrier says that the best liquid for injection in these cases is that devised by Byasson (water 1000 grammes, the white of one egg, and fifty-nine grammes of phosphate of soda), in which he was able to keep spermatozoa alive for twelve days at a temperature of 36° C.—*Med. Times and Gazette*, July 24, 1880.

A New Means for the Prevention of Hemorrhage in Operations upon the Female Genitals.

This is the title of a lengthy paper in the *Annales de Gynécologie*, Mai, 1880, by Professor **Courty**, of Montpelier. This remedy is the injection of hot water —that is, water as hot as the patient can bear it, practised several hours or several days beforehand, according to circumstances. The usefulness of such injections, he thinks, might be inferred beforehand, from the curious effect in stopping uterine hemorrhages, of heat applied, more or less near the uterus, in the lumbar region, or the vagina, etc. He refers, in illustration, to the writings of Chapman, Atthill, Gueneau de Mussy, and Emmet. He has now seen enough in his own practice, and that of others, to prevent him from having any doubt that hot-water injections will temporarily, if not permanently, arrest uterine hemorrhage. He looks upon it as a very natural transition from a hæmostatic action to infer a "decongestive." He has therefore often recommended hot-water injections in diseases accompanied with congestion, and with satisfactory results. From this he was led to recommend their frequent and prolonged use as a preparatory treatment for operations likely to be attended with hemorrhage. He has thus used it before performing incision of the cervix, removal of, or plastic operations upon, that part, vesico-vaginal fistula, etc., each time with the result, he believes, of much greater facility in the performance of the operation from the absence of the oozing which often obscures the surgeon's view of the parts he is dealing with, as well as with much less actual loss of blood. He does not think it is necessary for the patient, in using these injections, to assume the inconvenient posture usually recommended—*i. e.*, the pelvis raised, shoulders low, thigh flexed, etc.—but considers them equally efficient if the patient uses them on an ordinary bidet, and with a syringe capable of containing a good volume of fluid, and of being introduced well up into the posterior cul-de-sac. These latter points he looks upon as of great importance.—*Obstetrical Journal of Great Britain*, July, 1880.

Rudimentary Müller's Duct with Hernia of the Left Uterine Horn.

LEOPOLD reports the case of a patient (*Archiv für Gynäkologie*, Band xiv.), aged 28, who had been married eight years without children. She had never menstruated, but had, since her fourteenth year, regularly experienced severe menstrual pains, during which a tumour of the size of a plum in the left inguinal region swelled and became very painful. More recently, vicarious bleedings from the nose and lungs had appeared. On examination, a tumour of the size of half a hen's egg, uneven, and only slightly movable, was found. The vagina was only permeable for the tip of the index finger, measuring 3 centimetres in length, and ending in a *cul-de-sac*, in which no trace of the vaginal portion of the uterus could be found. The tumour in the inguinal region was diagnosed as an ovary, and it was determined to remove it on account of the suffering it caused. At the operation, the tumour was found to be the upper portion of a small uterus, with a Fallopian tube 6 centimetres long, and a somewhat small but well-developed ovary; below it was connected with the pelvic tissue by a narrow band. The tube, ovary, and uterus was ligatured and removed. The pedicle was tied and dropped in. Recovery was uninterrupted. The painful molimina have entirely ceased since the operation. The uterine cavity was of the size of a berry, filled with clear mucus; the mucous membrane was free from any appearance of old or recent hemorrhages. The ovary contained numerous follicles and corpora lutea. Dr. Leopold regarded the case as one of rudimentary development of Müller's duct, and congenital hernia of a rudimentary uterine horn. This last abnormity has hitherto only been described in one case, by Olshausen, in the *Archiv für Gynäkologie*, Band i. p. 41. In this case the left uterine horn, together with the ovary during pregnancy, could be detected in an inguinal hernia.—*Lond. Med. Record*, July 15, 1880.

On the Condition of the Uterine Mucous Membrane during Menstruation.

Dr. MOERICKE points out (*Centralblatt für Gynäkologie*, June 19th) that menstruation is a physiological process. If the general theory that the mucous membrane of the uterus were wholly, or completely, destroyed during menstruation were true, it would no longer be a physiological but a pathological process. Further, even, in certain diseases of the endometrium, we find that the epithelial coating is retained. He thinks that the theory of degeneration of the mucous membrane at the menstrual periods arose from the fact that the preparations examined were not fresh but exhibited *post-mortem* changes. The method which Dr. Moericke has adopted is to scoop off with a sharp curette a fresh piece of mucous membrane from the uterine surface. This he does at all stages of menstruation, before, during, and after. In every case, both in the fresh and the hardened preparations, he has found the epithelial covering completely preserved. In some cases it was found to be ruptured or perforated by an underlying blood-extravasation, but in no place was it degenerating.—*London Med. Record*, July 15, 1880.

Freund's Operation.

Kuhn relates two cases (*Centralblatt für Gynäkologie*, May 8, 1880). One case was that of a woman, aged 39, the mother of seven children. The body and cervix of the uterus were the seats of cancerous deposit. The operation of total extirpation of the uterus was decided on, and, on November 18, 1879, it was performed with Listerian precautions. The bladder was emptied by the catheter, the vagina washed out with a five per cent. carbolic solution, and then a colpeurynter was inserted, and distended so as to raise the uterus up towards the pelvic brim. Chloroform was administered. The abdominal incision was commenced one inch and a half below the umbilicus, and carried down close to the symphysis pubis. The uterus was seized with a Nélaton's forceps, and drawn up. The intestines were retained in the abdomen, by an assistant, in a warm moist cloth. The peritoneal covering of the uterus was intact. The ovaries were adherent to the tubes and broad ligaments on both sides. The body of the uterus was divided on each side from the broad ligament by a bistoury, and separated in the same way from the vaginal insertion. After the removal of the uterus, some bleeding took place from a branch of the left uterine artery, which was tied. The right and left ovaries were also ligatured and removed. The sutures were then drawn through the vagina, and the edges of the peritoneum brought accurately together in Douglas's pouch. The pelvic cavity was washed out with a two per cent. carbolic solution, and the abdominal wound closed with deep and superficial sutures. Lister's dressing was applied to the wound. At the beginning of January, the patient was able to leave her bed; she did not, however, continue to recover, for the discharge from the vagina re-appeared, and she died on March 14th. At the necropsy, cancerous growth was found in the upper part of the vagina and bladder. The second case was that of a woman, aged 40, mother of two children. The operation was performed March 2, 1880. The same precautions were used as in Case 1, and the same steps pursued in the operation. Both ovaries were removed as in Case 1, and their ligatures cut short and dropped back. The cancerous mass invaded the cervix and body of the uterus. The patient died fifteen hours after the operation, of collapse. At the necropsy, a dirty thick fluid was found among the intestines. The bladder and ureters were uninjured, and not pierced by the ligatures. There was a small blood clot in the pelvis. [Both these cases may be regarded as examples of the questionable value of Freund's operation. In the first case, the disease returned, as it always must when the neighbouring tissues are involved; and, in the second, the patient died of collapse. It is observed that the colpeurynter was passed into the vagina in order to bring the uterus up within operative reach. The reporter, when performing Freund's operation on the dead subject, found, at the suggestion of Dr. Garson, that the uterus was raised much higher by inserting the colpeurynter into the rectum, and then distend it with water.—*Rep.*]—*London Med. Record*, July 15, 1880.

Oöphorectomy.

Mr. **Lawson Tait** reports (*British Medical Journal*, July 10, 1880) twenty-eight cases of oöphorectomy performed by himself within the past twelve months. The operation was performed on account of dysmenorrhœa in twelve cases, of menstrual epilepsy and mania in two, of menorrhagia in two, of hemorrhage from myoma in eleven, and of abscess of ovary in one.

In twenty-six completed operations there was only one death, and Mr. Tait regrets ever having attempted the operation, as the patient was almost moribund when he saw her. There was also one death among the two incomplete operations, which warned Mr. Tait that, unless the ovaries can be fully removed, they had better not be touched.

Castration on account of Retroflexion of the Uterus.

Dr. E. Börner (*Wiener Medizinische Wochenschrift*, Nos. 19 and 20, 1880) properly defines the meaning of his title as being the removal of both healthy ovaries, in order to bring about the cessation of menstruation, and the retrograde metamorphosis of the uterus, and so to cause the sufferings caused by retroflexion to disappear. He reports the case of a patient who was twenty-six, unmarried, and had suffered from the retroflexion for seven years. She had severe dysmenorrhœa, which, from the absence of all appearances of inflammation, was believed to depend solely upon the flexion. She had been treated, both generally and locally, by many medical men without benefit. Division of the cervix, with subsequent introduction of thick bougies, continued for a long time, only once produced relief to the menstrual pain. Treatment by intra-uterine pessaries failed on account of the great sensitiveness of the uterus, and vaginal pessaries could only be tolerated in the inter-menstrual period. During menstruation there were several hysterical convulsions, and very painful uterine contractions, which would gradually extend to the whole muscular system. There was complete loss of sleep, and all nutriment was refused, and this lasted nearly a week each time. The patient's strength was the more enfeebled by her having resorted to morphia, so that any slight irritation brought on divers hysterical symptoms. In this state of things castration was resorted to. The incision was made in the linea alba. The ovaries were not adherent. The patient recovered from the operation, leaving her bed four weeks afterwards. Menstruation should normally have recurred on the sixth day after the operation. It actually happened two days afterwards, but lasted four days only. The next three months passed without either hemorrhage or the customary pains. The following month there was "a trace hardly worth naming," and the accompanying pains were reduced to such a minimum that occasional rest in bed during one or two days was enough to relieve them. The two following months there was no hemorrhage. The author therefore considers that the result aimed at by the operation was completely attained. The symptoms occasioned by the retroflexion (sacral pain, etc.) gradually went away, although no care was taken to correct the deviation. The author sums up the position of this operation among the modes of treatment suitable for flexion, as follows: Deviations of the uterus accompanied with severe suffering may form an indication for castration, if every kind of treatment directed to the causal conditions of the flexion has been tried and found without benefit, and some contra-indication is present which prevents mechanical treatment from being tried, and yet relief is urgently called for. Among the contra-indications for mechanical treatment (which therefore may be spoken of as indications for castration) are certain kinds of inflammation—peri- and para-metritis with effusion, or acute inflammation of the uterus itself—and bleeding, unless this has arisen from venous congestion the result of the flexion. Also certain kinds of adhesions, such as render reposition difficult and painful; and abnormal sensitiveness of the displaced uterus to mechanical interference.—*Obstetrical Journal of Great Britain*, July, 1880.

Medical Jurisprudence and Toxicology.

Poisoning by Tincture of Arnica.

Another fatal case of poisoning by tincture of arnica is reported from Italy. A man, apparently in perfect health, drank a quantity of tincture of arnica estimated at from two ounces to two ounces and a half. He immediately complained of a sensation of burning at the stomach. Bicarbonate of soda was given, and afterwards some aromatic tincture. By these his sufferings were relieved for some hours, but the pain subsequently returned, and he died thirty-six hours after having taken the poison. This case suggested some experiments as to the irritating character of arnica. An ounce of tincture of arnica was evaporated and yielded an extract, a little of which spread over the skin caused a papular eruption. A larger quantity produced vesication, just as does cantharides. The residue found in the stomach of the poisoned man, evaporated, and then applied to the skin, produced effects exactly the same as those caused by the evaporated tincture.—*Lancet*, July 10, 1880.

Poisoning by Bronze-Powder.

The coroner for Middlesex recently concluded an inquiry as to the death of a boy aged 13, which, it was alleged, arose from inhaling bronze-powder while employed at the printing establishment of Messrs. Clay, Son, and Taylor. Bronze-powder consists of an alloy of copper (in very fine powder) and is used in printing in gold. The printing is done by means of a mixture of size and gamboge, the powder is then dusted over, and the superfluous portion wiped off with wool. The boy mentioned to his parents that the powder got up his nose, and produced a tingling in his nostrils. On the fourth day of this work (June 10th), he complained of sickness and pain in the bowels. On the 13th, Mr. C. W. Latham was sent for to visit him; he was still suffering from sickness and pain, with great distension of the abdomen, and tenderness on pressure; no diarrhœa. He fell into a state of collapse, and died on the 18th. By order of the coroner, Mr. Latham made a post-mortem examination on the 22d, and found that death had resulted from peritonitis; the mucous membrane of the stomach and intestines was not affected. He removed the stomach and a portion of the liver, which were analyzed by Dr. Tidy, who found that both contained copper; and who gave it as his opinion that the deceased had died from the effects of metallic copper-poisoning, and that he had inhaled the poison in the process of bronzing. Evidence was given to the effect that it was customary in printing establishments where bronzing was going on for the persons engaged in it to be allowed a certain quantity of milk daily, owing to the dangerous nature of the work; and a lad named Grayling stated that, while employed on the same kind of work, he became ill, and was compelled to give it up in consequence. On behalf of the firm, evidence was given by persons in their service, who stated that they never experienced any ill effects while engaged in the bronzing process. Dr. Meymott Tidy suggested to the notice of employers: 1. The free use of milk; 2. That the persons engaged in bronzing should wear a covering over the nostrils and mouth; 3. That the bronzing should be carried out in a separate room, and not in the general workshop, in order as far as practicable to limit the injurious effects of the process; 4. That a dress composed of calico or like material, tied round the neck and wrists, should be worn by those engaged on the work, and removed before leaving the premises; 5. That cleanliness should be strictly enforced, and the persons engaged in bronzing required to wash themselves before leaving the premises. The jury returned a verdict in accordance with the evidence of Dr. Tidy.—*British Med. Journal*, July 24, 1880.

MEDICAL NEWS.

SCHOOL HYGIENE.

AFTER his summer's vacation the schoolmaster is again abroad in the nd, and this seems an opportune time for us to call attention to one or wo of the more important hygienic laws which are frequently neglected n the eager pursuit after knowledge, and for want of the wisdom which ngers far behind the pedagogue's track, are violated frequently in such a anner as to render scanty the return from his most earnest efforts or even light utterly the harvest of his toil.

When an educational centre like Princeton College is managed in such agrant violation of the dictates of sanitary science that typhoid fever one of the eminently filth diseases of Mr. Simon) becomes rife within s precincts, proves fatal to its students, and necessitates the dismissal of s classes before the close of its regular term, the time has surely arrived r our profession to urge everywhere a more faithful attention to school ygiene.

One of the most important disadvantages to which the army of ten illion American school children is subjected is the deprivation of suffi-ent pure air. In some of the worst schools the allowance of floor space as been reduced, by overcrowding infant pupils, to only two square feet, nd the cubical air space to fifteen cubic feet per scholar. The average uantity of floor space allotted to each pupil should not be less than twenty-ive square feet, and the air space ought to be at least two hundred and fty cubic feet. In order to fulfil these requirements an apartment in-ended to be occupied by twenty-five scholars should be about thirty-two eet long, twenty wide, and ten high, and even then careful attention to entilation and heating is necessary, or else impurity of the contained tmosphere during school hours will manifest itself not only to the sense f smell but in the languid and pallid aspect of the pupils. The presence f organic impurity from respiration to excess in the air of a school-room r other apartment can be quickly determined by Angus Smith's ready ethod of shaking half an ounce of fresh lime-water with ten fluidounces of the suspected air; when, if too impure for respiration, a milky precipitate is produced.

A greater danger of, however, a lesser evil lies in the tendency to produce myopia from want of sufficient amount or faulty direction of the light by which study is carried on. So much has been written on this subject of late that it is scarcely needful to more than remind our readers that the labours of Cohn, Erismann, Liebriech, and others, have demonstrated a direct connection between the increase of near-sightedness and improper or excessive study under imperfect illumination. The windows by which a school-room are lighted should occupy the wall of the apartment on the pupil's left hand, and correspond in area to one-fourth, or at any rate, one-fifth of the floor space. When it is difficult to obtain so full an illumination from the left side, part of the light may be allowed to enter from the right side, but illumination from in front of, or from behind the scholars, should always be avoided; class books of all kinds ought to be printed in large type, on clear, white or faintly tinted blue paper, and all punishments which involve prolongation of the hours of study had better be exchanged for the discipline of complete and wearisome quiet, or of some form of fatiguing gymnastic exercise. Enthusiastic pupils on the other hand should be cautioned against applying themselves too closely to their books at home, under the disadvantages of dim artificial light, or in constrained positions of the body or a recumbent posture.

Much injury to the growing organisms of children is often inflicted during school life by faulty construction of the desks and benches or chairs furnished for the pupils. A very injurious habit of stooping forwards, thus compressing the lungs, and of bending down the head in such a way as to favour congestion of the visual apparatus, is often brought on by the tops of the desks being too nearly horizontal. The proper inclination of a desk lid upon which rests a book, used for reading or study, is 40° or 45°, but this angle should be reduced to about 20° during the progress of a writing lesson. The seats occupied by the scholars should be so placed that their anterior margins are in perpendicular lines beneath the edges of the desks; they should be broad enough to fully support the thighs, and ought to be supplied with backs inclined only a few degrees from the perpendicular, and supporting the pupil's spine at a point one inch below the level of the desk for boys, and about two inches higher up for girls. Desks and benches ought always to be accurately adapted to the stature of the scholars.

The frequency with which contagious diseases are disseminated by means of schools can scarcely be calculated, and in fact the danger from this source is so great, and so constantly impending that stringent regulations for its reduction are urgently required. During the alarm concerning smallpox in Philadelphia last winter, an imperfect effort was made to require children attending our public schools to give proof that they had been successfully vaccinated before admission, but no systematic attempt has, we believe, been made in this country to prevent the spread of scarlet fever, diphtheria, whooping-cough, measles, etc., in this manner. Children convalescing from these and other infectious maladies are often returned to school in order that they may make up for lost time as rapidly as possible, or even because they are restless and troublesome at home, with abundant supplies about their persons of germ-disease poison which they sow broadcast among their schoolmates. Too frequently in the ignorance, carelessness, or feeble moral sense of guardians a slight benefit to the child is thus allowed to outweigh far-reaching injury to the community at large.

So great is the risk of serious or fatal disease being conveyed in this manner that we think private schools, where the principals require certificates from attending physicians to the effect that a returning convalescent is free from danger to other pupils, would be warmly sustained by the intelligent public, and when the value of some such precaution became recognized, as it soon must be, our authorities could doubtless ere long be persuaded to introduce it into all the primary and district schools of the land.

The importance of school hygiene can scarcely be over-estimated, because it is especially during their school life that our children acquire so large a part of the deformity and disease from which they suffer, and we have gladly embraced the period when, as at present, the minds of parents are directed towards the subject of school arrangements, to urgently invite attention to some of the more injurious, and, at the same time, more easily remedied defects, which mar the efficiency of our schools.

Transposition of the Viscera.—The *Moniteur du Calvados* reports a case of complete inversion of the thoracic and abdominal organs discovered in a post-mortem examination of the body of a young girl aged 17, under the care of Dr. Denis Dumont, principal surgeon to the Hôtel-Dieu Hospital at Caen. The whole of the viscera, although of perfectly normal form and structure, had undergone so thorough a displacement, that those of the right side were lodged in the left, and *vice versâ*. The left lung presented three lobes, whilst the right lung had only two. The heart was situated on the right side, and the arch of the aorta was directed to the same side. The liver occupied the left hypochondrium; the stomach and the spleen had taken its place in the right hypochondrium. Finally, the intestinal mass had undergone an analogous transposition. The relations of the organs to each other were perfectly retained, so that this arrangement in no way detracted from the perfectness of their functions. It was a well-marked example of that monstrosity known as splanchnic inversion, of which several cases, both in the living and in the dead subject, have been recorded in medical literature.—*British Med. Journal*, July 10, 1880.

Narcolepsy.—Under the name "narcolepsy" M. GFLINEAU describes in the *Gazette des Hôpitaux*, a rare form of neurosis, characterized by an irresistible desire to sleep, sudden in its onset, lasting but a short time, and recurring at more or less prolonged intervals. This neurosis has some analogies with somnolence and catalepsy. It was described for the first time, in 1862, by Dr. Casse, who referred it to a serous and passive congestion of the meninges and of the brain. The persons suffering from it fall asleep any moment; their sleep lasts for a few minutes and they then recover their consciousness. The patient whose case is reported by M. Galineau fell asleep in this way four or five times during his dinner, letting his knife or fork fall, and breaking off in the middle of a sentence he was uttering. Up to the present time, the most varied kinds of treatment have not given any good result.—*Brit. Med. Journal*, July 31, 1880.

Hydrophobia.—M. **Maurice Raynaud** inoculated a rabbit with the saliva of a hydrophobic patient, and the rabbit took the disease in five days. Two other rabbits inoculated with hydrophobic saliva also became hydrophobic. The conclusion drawn is that the saliva of hydrophobic patients is virulent and that this fact merits more attention than is now generally given to it.—*Brit. Med. Journal*, July 31, 1880.

—

Cod-Liver Oil and Iodoform.—Dr. **Fonssagrives** having ascertained (*Progrès Méd.*, June 19) that the addition of iodoform and essence of anise effectually masks the repulsive taste of cod-liver oil, always employs this combination i cases where the union of iodine with cod-liver oil is indicated, iodine being conveyed into the economy in a larger proportion by means of iodoform than by any other preparation. Patients, after comparing this mode of taking cod-liver with the ordinary modes, unanimously declare in favour of the taste and smell the former. To one hundred grammes of the oil a quarter of a gramme of iod form and ten drops of the aniseed are added.—*Med. Times and Gazette*, Ju 3, 1880.

—

Certification of the Correctness of Clinical Thermometers.—The Winchest Observatory of Yale College has undertaken, under proper regulations, to veri thermometers sent to the observatory and to issue certificates of the same in li manner as is now done at the Kew Observatory in England. Thermometers mus be sent at the expense and risk of the sender. The charge for verifying a clinica thermometer has been fixed at fifty cents.

—

International Medical Congress, London, 1881.—The International Medic Congress of 1881, will be held at London, August 3d to 9th inclusive. Th Congress will be under the patronage of the Queen and Prince of Wales.

The work of the Congress will be carried on in fifteen sections. The meetin will be held chiefly in the halls of the University of London, and in Burlingto House. Besides the general and sectional meetings, there will be a museum, t which contributions of professional interest will be made.

The executive committee have nominated the following as officers of the Congress: President, Sir James Paget, Bart., LL.D., D.C.L., F.R.S. Section I *Anatomy*, President, Prof. Flower. Section II. *Physiology*, President, Prof. Michael Foster. Section III. *Pathology and Morbid Anatomy*, President, Dr. Samuel Wilks. Section IV. *Medicine*, President, Sir William Gull. Section V. *Surgery*, President, John Eric Erichsen, Esq. Section VI. *Obstetric Medicine and Surgery*, President, Dr. McClintock, of Dublin. Section VII. *Diseases of Children*, President, Dr. West. Section VIII. *Mental Diseases*, President, Dr. Lockhart Robertson. Section IX. *Ophthalmology*, President, William Bowman, Esq. Section X. *Diseases of the Ear*, President, William B. Dalby, Esq. Section XI. *Diseases of the Skin*, President, Erasmus Wilson, Esq. Section XII. *Diseases of the Teeth*, President, Edwin Saunders, Esq. Section XIII. *State Medicine*, President, John Simon, Esq. Section XIV. *Military Surgery and Medicine*, President, Surgeon-General Professor Longmore. Section XV. *Materia Medica and Pharmacology*, President, Professor T. R. Fraser, M.D.

Papers may be read in English, French, or German, and their authors are requested to intimate their intentions before the end of March, 1881, and to send an abstract of their papers before May 31, to William MacCormac, Esq., Hon. Secretary-General, 13 Harley Street, London, W.

Society Meetings.—The American Gynæcological Society will hold its annual meeting in Cincinnati on the 1st, 2d, and 3d of September. The Canada Medical Association meets this year at Ottawa on the 1st of September.

Connecticut Medical Society held its eighty-ninth annual convention at New Haven, May 26th and 27th, Dr. A. R. Goodrich, of Vernon, presiding. The following officers were chosen for the ensuing year: President, Dr. G. L. Platt, of Waterbury; Vice-President, Dr. Wm. Deming, of Litchfield; Secretary, Dr. C. W. Chamberlain, of Hartford. The next annual convention will be held at Hartford on the fourth Wednesday in June, 1881.

Maine Medical Association.—This Society held its twenty-eighth annual meeting at Portland on the 15th, 16th, and 17th of June, Dr. S. C. Gordon, of Portland, presiding. A number of essays and reports of cases were presented. Dr. O. A. Horr, of Lewiston, delivered the annual oration. The Society's visitors reported the Medical School of Maine and the Portland School for Medical Instruction to be in a very prosperous condition. At the latter school two-thirds of the candidates were stated to have been rejected at the preliminary examination in June.

The following officers were elected for the ensuing year: President, William Warren Greene, M.D., of Portland; Secretary, Dr. C. O. Hunt, of Portland. The next meeting will be held on the third Tuesday in June, 1881.

New Hampshire Medical Society held its ninetieth annual meeting at Concord, June 15th and 16th, Dr. T. J. W. Pray, of Dover, presiding. It was decided to hold the semi-annual meeting at Plymouth on the 2d of September, and it was stated that on the 3d the delegates and their families would be tendered an excursion upon Lake Winnepesaukee. The following officers were elected for the ensuing year. President, Dr. G. P. Conn, of Concord; Vice-President, Dr. H. B. Fowler, of Bristol; Secretary, Dr. M. W. Russell, of Concord. The next annual meeting will be held at Concord on the third Tuesday of June, 1881.

Medical College of Virginia.—The friends of better medical education will be gratified to learn that the Medical College of Virginia and the University of Virginia have made a departure in favour of the elevated standard of medical education. They have instituted a graded course and extended the term to nine months, with an examination at the end of each year. While the condition of these institutions may not warrant any further change at this time, we trust that this step will speedily elicit sufficient encouragement to justify the authorities in instituting a preliminary examination, and adding a third year to the course. As it is the medical student should feel grateful at the improved facilities which are now afforded to him.

Fiske-Fund Prize.—The Fiske-Fund Prize Committee of the Rhode Island Medical Society announce that, for 1881, a prize of $150 is offered for the best essay on either of the following subjects: "The Action of Medicine on the Cure of Diseases," and "Uterine and Ovarian Diseases as a Cause of Insanity."

The Volta Prize.—The Volta Prize of 50,000 francs has been awarded by the French Government to Prof. Graham Bell, of Boston, for his invention of the articulating electro-magnetic telephone.

Cammann's Binaural Stethoscope.—Mr. William Snowden, surgical instrumen maker of this city, has modified this form of stethoscope by adding a soft rubb cup to the chest end, which permits a more accurate application to the thora parietes, and soft rubber pads to the ear-pieces, which effectually exclude exter sounds. The flexible tubes are freed from all woollen or silk coverings, and th all friction sound arising from this source is avoided. These modifications, wi also a change in the manner of applying the spring pressure to the ear-piec have resulted in a decided diminution in the cost of the instrument.

Personal.—It is announced that Dr. Sigmund, Professor of Syphilis in t University of Vienna, having reached his seventieth year, will retire upon pension.

OBITUARY RECORD.—Died at Paris on the 8th of July, aged 56, PA BROCA, Senator and Professor of Clinical Surgery in the Paris Faculty. Broca acquired a world-wide reputation by his works on Aneurisms, published 1856; on Tumours, published ten years later; and by his researches in Anth pology; indeed he may be said to have been the founder of that science. C cerning his important researches in aphasia the *British Medical Journal* (J 24, 1880) says: "The localization of the faculty of speech is one of the grea discoveries of modern science. M. Bouillaud had shown that aphasia gener coincides with a lesion of the left hemisphere; but M. Broca, studying t anatomical lesion and the functional disturbance more minutely, demonstrat that aphasia is coincident with the destruction of a limited region of the enceph lon—the posterior part of the third left frontal convolution. When that regi is destroyed, speech is gone; so long as it is retained, speech remains. This the rule—a rule almost without exception; and the exceptions even are far fr incontestable. This was, as a matter of fact, one of the most interesting scientific discoveries; it was, indeed, the first cerebral localization, and is at t present time the most precise and important. Since that time, the mechanism the encephalon has been easier of comprehension. It is true that this mechani is still very obscure, and of such a complex nature that it is difficult to concei when it will be clearly and simply made out; but it is none the less true th thanks to the precise determination of the aphasic lesion, it is known that the are regions in the brain where certain intellectual functions originate and beco elaborated, to manifest themselves outwardly in the form of movements. T knowledge of this important and essential fact is due exclusively to M. Broc (*Bulletins de la Société Anatomique*, 1861).

—— At New Orleans, on the 2d of May, of pneumonia, SAMUEL CHOPPI M.D., aged 52 years. Dr. Choppin was a native of Louisiana, and was one the founders of the New Orleans School of Medicine.

—— At London, on the 27th of May, in his seventy-fourth year, ALFRE SWAINE TAYLOR, M.D., F.R.S., late Professor of Medical Jurisprudence Guy's Hospital.

Dr. Taylor had a world-wide reputation as an expert in all matters relating t medical jurisprudence and toxicology, and his works on "Poisons" and "Medical Jurisprudence" are universally esteemed as standard authorities.

—— At Ramsgate, on the 27th of May, S. MESSENGER BRADLEY, M.D., one of the Surgeons to the Manchester Royal Infirmary.

***To Readers and Correspondents.**—The editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.*

HENRY C. LEA'S SON & CO.'S

(LATE HENRY C. LEA)

LASSIFIED CATALOGUE

OF

MEDICAL AND SURGICAL PUBLICATIONS.

asking the attention of the profession to the works advertised in the following s, the publishers would state that no pains are spared to secure a continuance of onfidence earned for the publications of the house by their careful selection and racy and finish of execution.

he large number of inquiries received from the profession for a finer class of bind- than is usually placed on medical books has induced us to put certain of our dard publications in half Russia, and that the growing taste may be encouraged, prices have been fixed at so small an advance over the cost of sheep, as to place it the means of all to possess a library that shall have attractions as well for the s for the mind of the reading practitioner.

e printed prices are those at which books can generally be supplied by book- s throughout the United States, who can readily procure for their customers any not kept in stock. Where access to bookstores is not convenient, books will be y mail post-paid on receipt of the price, and as the limit of mailable weight has removed, no difficulty will be experienced in obtaining through the post-office ork in this catalogue. No risks, however, are assumed either on the money or e books, and no publications but our own are supplied, so that gentlemen will in cases find it more convenient to deal with the nearest bookseller.

Illustrated Catalogue, of 64 octavo pages, handsomely printed, will be rded by mail, post-paid, on receipt of ten cents.

INCREASED INDUCEMENT FOR SUBSCRIBERS TO

AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

TWO MEDICAL JOURNALS, containing nearly 2000 LARGE PAGES,

Free of Postage, for FIVE DOLLARS Per Annum.

TERMS FOR 1880.

American Journal of the Medical Sciences, published quarterly (1150 pages per annum), with Medical News and Abstract, monthly (768 pp. per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

American Journal of the Medical Sciences, when not paid for in advance, Five Dollars.

Medical News and Abstract, free of postage, in advance, Two Dollars and a half.

* Advance paying subscribers can obtain at the close of the year cloth covers, lettered, for each volume of the Journal (two annually), and of the News and tract (one annually), free by mail, by remitting ten cents for each cover.

will thus be seen that for the moderate sum of Five Dollars in advance, the riber will receive, free of postage, the equivalent of three or four large octavo mes, stored with the choicest matter, original and selected, that can be furnished he medical literature of both hemispheres. Thus taken together, the "Journal," the "News and Abstract" combine the advantages of the elaborate prepara- that can be devoted to the Quarterly with the prompt conveyance of intelligence he Monthly; while the whole being under a single editorial supervision, the sub- ber is secured against the duplication of matter inevitable when periodicals from rent sources are taken together.

he periodicals thus offered at this unprecedented rate are universally known for

(For "The Obstetrical Journal," see p. 24.)

their high professional standing.

I.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENC

EDITED BY I. MINIS HAYS, M.D.,

for more than half a century has maintained its position in the front rank medical literature of the world. Cordially supported by the profession of Ameri circulates wherever the language is read, and is universally regarded as a natio ponent of American medicine—a position to which it is entitled by the disting names from every section of the Union which are to be found among its collabora It is issued quarterly, in January, April, July, and October, each number cont about three hundred octavo pages, appropriately illustrated wherever necessary large portion of this space is devoted to Original Communications, embracing from the most eminent members of the profession throughout the country.

Following this is the REVIEW DEPARTMENT, containing extended reviews by petent writers of prominent new works and topics of the day, together with nu elaborate Analytical and Bibliographical Notices, giving a fairly complete sur medical literature.

Then follows the QUARTERLY SUMMARY OF IMPROVEMENTS AND DISCOV IN THE MEDICAL SCIENCES, classified and arranged under different heads, and ishing a digest of medical progress, abroad and at home.

Thus during the year 1879 the "JOURNAL" contained 67 Original Communic mostly elaborate in character, 147 Reviews and Bibliographical Notices, and 215 in the Quarterly Summaries, illustrated with 70 wood engravings.

That the efforts thus made to maintain the high reputation of the "JOURNAL successful, is shown by the position accorded to it in both America and Europ leading organ of medical progress:—

This is universally acknowledged as the leading American Journal, and has been conducted by Dr. Hays alone until 1869, when his son was associated with him. We quite agree with the critic, that this journal is second to none in the language, and cheerfully accord to it the first place, for nowhere shall we find more able and more impartial criticism, and nowhere such a repertory of able original articles. Indeed, now that the "British and Foreign Medico-Chirurgical Review" has terminated its career, the American Journal stands without a rival.—*London Med. Times and Gazette*, Nov. 24, 1877.

The best medical journal on the continent.—*Boston Med. and Surg. Journal*, April, 1879.

The present number of the American Journal is an exceedingly good one, and gives every promise of maintaining the well-earned reputation of the review. Our venerable contemporary has our best wishes, and we can only express the hope that it may continue its work with as much vigor and excellence for the next fifty years as it has exhibited in the past.—*London Lancet*, Nov. 24, 1877.

The Philadelphia Medical and Physical issued its first number in 1820, and, after a career, was succeeded in 1827 by the A Journal of the Medical Sciences, a peri world-wide reputation; the ablest and one oldest periodicals in the world—a journal w an unsullied record.—*Gross's History of A Med. Literature*, 1876.

The best medical journal ever published in or America.—*Va. Med. Monthly*, May, 187

It is universally acknowledged to be the American medical journal, and, in our o second to none in the language.—*Boston Surg. Journal*, Oct. 1877.

This is the medical journal of our country the American physician abroad will point w greatest satisfaction, as reflecting the state o cal culture in his country. For a great many it has been the medium through which our writers have made known their discove observations.—*Address of L. P. Yandell, M fore International Med. Congress*, Sept. 187

And that it was specifically included in the award of a medal of merit to the lishers in the Vienna Exhibition in 1873.

The subscription price of the "AMERICAN JOURNAL OF THE MEDICAL SCIEN has never been raised during its long career. It is still FIVE DOLLARS per a and when paid for in advance, the subscriber receives in addition the "M NEWS AND ABSTRACT," making in all nearly 2000 large octavo pages per annu of postage.

II.

THE MEDICAL NEWS AND ABSTRACT.

Thirty-seven years ago the "MEDICAL NEWS" was commenced as a mon convey to the subscribers of the "AMERICAN JOURNAL" the clinical instructi rent information which could not be accommodated in the Quarterly. It consisted sixteen pages of such matter, together with sixteen more known as the Library partment and devoted to the publishing of books. With the increased progress of nce, however, this was found insufficient, and some years since another periodical, own as the "MONTHLY ABSTRACT," was started, and was furnished at a moderate ce to subscribers to the "AMERICAN JOURNAL." These two monthlies will here- r be consolidated, under the title of "THE MEDICAL NEWS AND ABSTRACT," will be furnished *free of charge* in connection with the "AMERICAN JOURNAL." he "NEWS AND ABSTRACT" will consist of 64 pages monthly, in a neat cover. It l contain a CLINICAL DEPARTMENT in which will be continued the series of ORIGI- L AMERICAN CLINICAL LECTURES, by gentlemen of the highest reputation ughout the United States, together with a choice selection of foreign Lectures and pital Notes and Gleanings. Then will follow the MONTHLY ABSTRACT, systemati- y arranged and classified, and presenting five or six hundred articles yearly; and h number will conclude with a NEWS DEPARTMENT, giving current professional ligence, domestic and foreign, the whole fully indexed at the close of each volume, ering it of permanent value for reference.

---

* Communications are invited from gentlemen in all parts of the country. Elaborate articles by the Editor are paid for by the publishers.

s stated above, the subscription price to the "NEWS AND ABSTRACT" will be Dollars and a Half per annum, invariably in advance, at which rate it will rank e of the cheapest medical periodicals in the country. But it will also be fur- d, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE ICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the riber, for that very moderate sum, a complete record of medical progress through- e world, in the compass of about two thousand large octavo pages.

this effort to furnish so large an amount of practical information at a price so un- edentedly low, and thus place it within the reach of every member of the profes- the publishers confidently anticipate the friendly aid of all who feel an interest in dissemination of sound medical literature. They trust, especially, that the sub- rs to the "AMERICAN MEDICAL JOURNAL," will call the attention of their intances to the advantages thus offered, and that they will be sustained in the avor to permanently establish medical periodical literature on a footing of cheap- never heretofore attempted.

EMIUM FOR OBTAINING NEW SUBSCRIBERS TO THE "JOURNAL."

y gentleman who will remit the amount for two subscriptions for 1880, one of at least must be for a *new subscriber*, will receive as a PREMIUM, free by mail, y of any one of the following recent works:—

"BARNES'S MANUAL OF MIDWIFERY" (see p. 24),
"TILBURY FOX'S EPITOME OF DISEASES OF THE SKIN," new edition (see p. 18),
"FOTHERGILL'S ANTAGONISM OF MEDICINES" (see p. 16),
"HOLDEN'S LANDMARKS, MEDICAL AND SURGICAL" (see p. 6),
"BROWNE ON THE USE OF THE OPHTHALMOSCOPE" (see p. 29),
"FLINT'S ESSAYS ON CONSERVATIVE MEDICINE" (see p. 15),
"STURGES'S CLINICAL MEDICINE" (see p. 14),
"SWAYNE'S OBSTETRIC APHORISMS," new edition (see p. 21),
"TANNER'S CLINICAL MANUAL" (see p. 5),
"WEST ON NERVOUS DISORDERS OF CHILDREN" (see p. 20).

* Gentlemen desiring to avail themselves of the advantages thus offered will do to forward their subscriptions at an early day, in order to insure the receipt of plete sets for the year 1880.

The safest mode of remittance is by bank check or postal money order, drawn e order of the undersigned. Where these are not accessible, remittances for the OURNAL" may be made at the risk of the publishers, by forwarding in REGISTERED rs. Address,

HENRY C. LEA'S SON & CO., Nos. 706 and 708 Sansom St., Phila., Pa.

DUNGLISON (ROBLEY), M.D.,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: C taining a concise explanation of the various Subjects and Terms of Anatomy, Physi Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, M Jurisprudence, and Dentistry. Notices of Climate and of Mineral Waters; Formul Officinal, Empirical, and Dietetic Preparations; with the Accentuation and Etymol the Terms, and the French and other Synonymes; so as to constitute a French as w English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly ified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and h some royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, half Russia, $8. (*Just Issued.*)

The object of the author from the outset has not been to make the work a mere lexi dictionary of terms, but to afford, under each, a condensed view of its various medical relat and thus to render the work an epitome of the existing condition of medical science. Sta with this view, the immense demand which has existed for the work has enabled him, in rep revisions, to augment its completeness and usefulness, until at length it has attained the p of a recognized and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain thi viable reputation. During the ten years which have elapsed since the last revision, the add to the nomenclature of the medical sciences have been greater than perhaps in any similar of the past, and up to the time of his death the author labored assiduously to incorporate thing requiring the attention of the student or practitioner. Since then, the editor has equally industrious, so that the additions to the vocabulary are more numerous than in any vious revision. Especial attention has been bestowed on the accentuation, which will be marked on every word. The typographical arrangement has been much improved, rend reference much more easy, and every care has been taken with the mechanical execution. work has been printed on new type, small but exceedingly clear, with an enlarged page, s the additions have been incorporated with an increase of but little over a hundred page the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan. 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the "that the work, which possesses for him a filial as an individual interest, will be found worthy tinuance of the position so long accorded to standard authority."—*Cincinnati Clinic*, Jan. 1

It has the rare merit that it certainly has in the English language for accuracy and ex references.—*London Medical Gazette*

As a standard work of reference, as one of th if not the very best, medical dictionary in th lish language, Dunglison's work has been well for about forty years, and needs no words of on our part to recommend it to the members medical, and, likewise, of the pharmaceuti fession. The latter especially are in need of work, which gives ready and reliable infor on thousands of subjects and terms which th liable to encounter in pursuing their daily tions, but with which they cannot be expected familiar. The work before us fully suppli want.—*Am. Journ. of Pharm.*, Feb. 1874.

A valuable dictionary of the terms emplo medicine and the allied sciences, and of th tions of the subjects treated under each head. flects great credit on its able American auth well deserves the authority and popularity obtained.—*British Med. Journ.*, Oct. 31, 1874.

Few works of this class exhibit a grander ment of patient research and of scientific lore. extent of the sale of this lexicon is sufficient tify to its usefulness, and to the great service ferred by Dr. Robley Dunglison on the profe and indeed on others, by its issue.—*London L* May 13 1875.

HOBLYN (RICHARD D.), M.D.

A DICTIONARY OF THE TERMS USED IN MEDICINE A THE COLLATERAL SCIENCES. Revised, with numerous additions, by ISAAC H M.D., Editor of the "American Journal of the Medical Sciences." In one large 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00

It is the best book of definitions we have, and ought always to be upon the student's table.—*Sou Med. and Surg. Journal.*

RODWELL (G. F.), F.R.A.S., &c.

A DICTIONARY OF SCIENCE: Comprising Astronomy, Ch istry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magne Mechanics, Meteorology, Pneumatics, Sound, and Statics. Preceded by an Essay on History of the Physical Sciences. In one handsome octavo volume of 694 pages, many illustrations: cloth, $5.

A *CENTURY OF AMERICAN MEDICINE*, 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas, and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25. (*Lately Issued.*)

This work appeared in the pages of the American Journal of the Medical Sciences during the ar 1876. As a detailed account of the development of medical science in America, by gentle- s of the highest authority in their respective departments, the profession will no doubt wel e it in a form adapted for preservation and reference.

NEILL (JOHN), M.D., and SMITH (FRANCIS G.), M.D.,

Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

HARTSHORNE (HENRY), M.D.,

Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery, and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00. (*Lately Issued.*)

e can say with the strictest truth that it is the k work of the kind with which we are acquainted. mbodies in a condensed form all recent contribu- s to practical medicine, and is therefore useful very busy practitioner throughout our country, ides being admirably adapted to the use of stu- ts of medicine. The book is faithfully and ably uted.—*Charleston Med. Journ.*, April, 1875.

he work is intended as an aid to the medical dent, and as such appears to admirably fulfil its ect by its excellent arrangement, the full compi- on of facts, the perspicuity and terseness of lan- ge, and the clear and instructive illustrations ome parts of the work.—*American Journ. of rmacy*, Philadelphia, July, 1874.

e volume will be found useful, not only to stu- s, but to many others who may desire to refresh r memories with the smallest possible expendi- e of time.—*N. Y. Med. Journal*, Sept. 1874.

e student will find this the most convenient and ul book of the kind on which he can lay his d.—*Pacific Med. and Surg. Journ.*, Aug. 1874.

his is the best book of its kind that we have ever mined. It is an honest, accurate, and concise pend of medical sciences, as fairly as possible esenting their present condition. The changes the additions have been so judicious and tho- gh as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr. Hartshorne.—*Detroit Rev. of Med. and Pharm.*, Aug. 1874.

The work before us, however, has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation. It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the latest advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept. 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874.

LUDLOW (J. L.), M.D.

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy, and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations. In one handsome royal 12mo. volume of 816 large pages, cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suitable for the office examination of students, and for those preparing for graduation.

TANNER (THOMAS HAWKES), M.D., &c.

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS. Third American from the Second London Edition. Revised and Enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, &c. In one neat volume small 12mo., of about 375 pages, cloth, $1 50.

⁂ On page 3, it will be seen that this work is offered as a premium for procuring new bscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

GRAY (HENRY), F.R.S.,

Lecturer on Anatomy at St. George's Hospital, London.

ANATOMY, DESCRIPTIVE AND SURGICAL. The Drawings by H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the AUTHOR and Dr. CARTER. With an Introduction on General Anatomy and Development by T. HOLMES, M.A., Surgeon to St George's Hospital. A new American, from the eighth enlarged and improved London edition. To which is added "LANDMARKS, MEDICAL A SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Manu of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, wi 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, half Russia, $7 50. (*Just Ready.*)

The author has endeavored in this work to cover a more extended range of subjects than is cu tomary in the ordinary text-books, by giving not only the details necessary for the student, b also the application of those details in the practice of medicine and surgery, thus rendering it b a guide for the learner, and an admirable work of reference for the active practitioner. The e gravings form a special feature in the work, many of them being the size of nature, nearly original, and having the names of the various parts printed on the body of the cut, in place figures of reference, with descriptions at the foot. They thus form a complete and splendid seri which will greatly assist the student in obtaining a clear idea of Anatomy, and will also serve refresh the memory of those who may find in the exigencies of practice the necessity of recalli the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, wi a thorough treatise on systematic, descriptive, and applied Anatomy, the work will be found essential use to all physicians who receive students in their offices, relieving both preceptor a pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions at th hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has seeme requisite to maintain its reputation as a complete and authoritative standard text-book and wo of reference. Still further to increase its usefulness, there has been appended to it the rece work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Surgical —which gives in a clear, condensed, and systematic way, all the information by which the pra titioner can determine from the external surface of the body the position of internal parts. Th complete, the work, it is believed, will furnish all the assistance that can be rendered by type illustration in anatomical study. No pains have been spared in the typographical executio the volume, which will be found in all respects superior to former issues. Notwithstanding increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as heretof at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr Holden, which was noticed by us on p. 53 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view and in the valuable edition of Mr Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical*," which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The work simply indispensable, especially this present A ican edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. Hol as an appendix, renders this the most practical complete treatise available to American stude who find in it a comprehensive chapter on mi anatomy, about all that can be taught on gen and special anatomy, while its treatment of e region, from a surgical point of view, in the va able section by Mr Holden, is all that will be ess tial to them in practice.—*Ohio Medical Recor* Aug 1878.

It is difficult to speak in moderate terms of th new edition of "Gray." It seems to be as nea perfect as it is possible to make a book devoted any branch of medical science. The labors of th eminent men who have successively revised th eight editions through which it has passed, woul seem to leave nothing for future editors to do. T addition of Holden's "Landmarks" will make it indispensable to the practitioner of medicine a surgery as it has been heretofore to the student. A regards completeness, ease of reference, utility beauty, and cheapness, it has no rival. No stu dent should enter a medical school without it; n physician can afford to have it absent from his library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,

Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL. From the 2d London Ed. In one handsome volume, royal 12mo., of 128 pages: cloth, 88 cents. (*New Ready.*)

HEATH (CHRISTOPHER), F.R.C.S.,

Teacher of Operative Surgery in University College, London.

PRACTICAL ANATOMY: A Manual of Dissections. From th Second revised and improved London edition. Edited, with additions, by W. W. K M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philadelphi In one handsome royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3 5 leather, $4 00.

LLEN (HARRISON), M.D.
Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY: INCLUDING ITS MEDICAL and Surgical Relations. For the Use of Practitioners and Students of Medicine. With an Introductory Chapter on Histology By E. O. SHAKESPEARE, M D., Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. (*In Press.*)

In this elaborate work, which has been in active preparation for several years, the author has ght to give, not only the details of descriptive anatomy in a clear and condensed form, but also practical applications of the science to medicine and surgery. The work thus has claims upon attention of the general practitioner, as well as of the student, enabling him not only to re- sh his recollections of the dissecting room, but also to recognise the significance of all varia- ns from normal conditions. The marked utility of the object thus sought by the author is evident, and his long experience and assiduous devotion to its thorough development are a cient guarantee of the manner in which his aims have been carried out. No pains have been red with the illustrations. Those of normal anatomy are from original dissections, drawn on ne by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, r the manner of "Holden" and "Gray," and in every typographical detail it will be the rt of the publisher to render the volume worthy of the very distinguished position which is icipated for it.

LLIS (GEORGE VINER).
Emeritus Professor of Anatomy in University College, London.

DEMONSTRATIONS OF ANATOMY; Being a Guide to the Knowledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25 (*Just Ready.*)

his work has long been known in England as the leading authority on practical anatomy, the favorite guide in the dissecting-room, as is attested by the numerous editions through ch it has passed. In the last revision, which has just appeared in London, the accomplished hor has sought to bring it on a level with the most recent advances of science by making the essary changes in his account of the microscopic structure of the different organs, as devel- d by the latest researches in textural anatomy.

llis's Demonstrations is the favorite text-book the English student of anatomy. In passing gh eight editions it has been so revised and ed to the needs of the student that it would that it had almost reached perfection in this al line. The descriptions are clear, and the ods of pursuing anatomical investigations are with such detail that the book is honestly led to its name.—*St. Louis Clinical Record*, , 1879.

e success of this old manual seems to be as well rved in the present as in the past volumes. book seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

ILSON (ERASMUS), F.R.S.

A SYSTEM OF HUMAN ANATOMY, General and Special. Edited by W. H. GOBRECHT, M.D., Professor of General and Surgical Anatomy in the Medical College of Ohio. Illustrated with three hundred and ninety-seven engravings on wood. In one large and handsome octavo volume, of over 600 large pages; cloth, $4; leather, $5.

MITH (HENRY H.), M.D., and *HORNER (WILLIAM E.), M.D.,*
Prof. of Surgery in the Univ. of Penna., &c. *Late Prof. of Anatomy in the Univ. of Penna.*

AN ANATOMICAL ATLAS; illustrative of the Structure of the Human Body. In one volume, large imperial octavo, cloth, with about six hundred and fifty beautiful figures. $4 50.

CHAFER (EDWARD ALBERT), M.D.,
Assistant Professor of Physiology in University College, London.

A COURSE OF PRACTICAL HISTOLOGY: Being an Introduction to the Use of the Microscope. In one handsome royal 12mo. volume of 304 pages, with numerous illustrations: cloth, $2 00. (*Just Issued.*)

ORNER'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified. In 2 vols. 8vo., of over 1000 pages, with 320 wood-cuts: cloth, $6 00

ARPEY AND QUAIN'S HUMAN ANATOMY. evised, by JOSEPH LEIDY, M.D., Prof of Anat. Univ. of Penn. In two octavo vols. of about 00 pages, with 511 illustrations Cloth, $6 00.

LLAMY'S STUDENT'S GUIDE TO SURGICAL ANATOMY: A Text-book for Students preparing for their Pass Examination. With engravings on wood. In one handsome royal 12mo. volume Cloth, $2 25.

CLELAND'S DIRECTORY FOR THE DISSECTION OF THE HUMAN BODY. In one small volume, royal 12mo. of 182 pages: cloth $1 25

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. vol., with 220 wood cuts; cloth, $1 75.

CARPENTER (WILLIAM B.), M.D., F.R.S., F.G.S., F.L.S.,

Registrar to University of London, etc.

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWE M.B. Lond., F.R.C.S., Examiner in Natural Sciences, University of Oxford. A ne American from the Eighth Revised and Enlarged English Edition, with Notes and Addi tions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the Unive sity of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pag with two plates and 373 engravings on wood; cloth, $5 50; leather, $6 50; half R $7. (*Just Issued.*)

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago, looks now as if it had be received and established fact for years. In this c clopædic way it is unrivalled. Here, as it seem us, is the great value of the book: one is safe in sen a student to it for information on almost any g subject, perfectly certain of the fulness of inform it will convey, and well satisfied of the accuracy which it will there be found stated.—*London Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so w known and appreciated that we need only allude to the fact that in the latest edition will be found a prehensive embodiment of the results of recent ph logical investigation. Care has been taken to pre the practical character of the original work. In the entire work has been brought up to date, and evidence of the amount of labor that has been best upon it by its distinguished editor, Mr. Henry P The American editor has made the latest additi order fully to cover the time that has elapsed since last English edition.—*N. Y. Med. Journal*, Jan. 18

FOSTER (MICHAEL), M.D., F.R.S.,

Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. A new American, from the l English edition. Edited with notes and additions by EDWARD T. REICHERT, M Demonstrator of Experimental Therapeutics in Univ. of Penna. In one handsome r 12mo. volume of 1030 pages, with 259 illustrations. Cloth, $1 50. Leather, $2 (*Just Ready.*)

AMERICAN EDITOR'S PREFACE.

The high reputation acquired on both sides of the Atlantic by Dr. Foster's "Text-Boo Physiology," as a lucid exposition of functional physiology, in its most modern aspect, has see to call for an edition more thoroughly adapted to the wants of the American student. The of the author has presupposed an acquaintance with the details of physiological anatomy su the student is accustomed to look to in his treatises on physiology. The absence of t details has rendered many parts of the work vague, if not altogether incomprehensible, and therefore proved a serious drawback to the usefulness of the book as an accompaniment to tures on physiology, as it is usually taught in our schools, and this deficiency the editor endeavored to supply, by brief notes and the introduction of a large number of illustrations.

The almost limitless amount of material accumulated by modern research has rendered d cult the task of selection and compression, without exceeding the reasonable limits of a co nient text-book. In his selection the editor has been guided by his experience in the want students, and has endeavored merely to present, in the most concise form, such facts as would se to be indispensable to a correct appreciation of the structure and function of the import organs. In accomplishing this, his additions have considerably exceeded his expectatio amounting to about 140 pages, including the illustrations which have been increased in numb from 72 to 259 If he shall thus have succeeded in rendering this admirable work better fi for the wants of the American student, he will feel abundantly rewarded.

Nothing has been omitted from the English edition, and all additions have been dist guished by insertions in brackets [—].

The great popularity of "Foster's Text-book of Physiology," both in England and in this country, renders it unnecessary to say anything further regarding its merit. We shall, therefore, simply point out that, in the American edition, numerous important additions have been made to the text of the third English edition whereby the usefulness of the work as a text-book for students has been greatly increased.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

Foster's Physiology is a most excellent book, not only for the student, but especially for the physician who wishes to revise and increase his physiological knowledge. The style of the author is clear, his arrangement and classification of subjects very satisfactory and he has presented in this volume a most valuable exposition of physiology as now known.—*The Am. Practitioner*, April, 1880.

Every sentence shows careful and mature thought, and the student, at the outset, will have to make up his mind that Foster's work requires *study*, and not simply a cursory reading. The work is well ill trated, and its method clear and logical, and e nently practical, and fully up to the present a vanced status of this most important branch medicine. Foster's work is a credit to his schol ship and research, and will be accepted everywh by the student and practitioner as reliable author It should be in the hands of every medical stud —*St. Louis Clin. Record*, April, 1880.

The matter of the last English edition has be transferred bodily to this, and there have b added very many illustrations and copious not on histology and embryology by the American ed or. The English editions have been defective. as far as American students are concerned, in the dearth of illustrations and the absence of all dis sion of physiological anatomy These being s plied in this edition, the work is now undoubt the best on physiology in the English languag *Ohio Med. Recorder*, June, 1880.

THE SAME. English Student's Edition, without notes or additions. Latest issue. In one small 12mo. volume of 804 pages with 72 illustrations. Cloth, 75 c

DALTON (J. C.), M.D.,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Sixth edition, thoroughly revised and enlarged, with three hundred and sixteen illustrations on wood. In one very beautiful octavo volume, of over 800 pages. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Issued.*)

During the past few years several new works on phy- logy, and new editions of old works, have appeared, npeting for the favor of the medical student, but ne will rival this new edition of Dalton. As now en- ged, it will be found also to be, in general, a satisfac- y work of reference for the practitioner.—*Chicago . Journ. and Examiner*, Jan. 1876.

rof. Dalton has discussed conflicting theories and lusions regarding physiological questions with a ness, a fulness, and a conciseness which lend fresh- s and vigor to the entire book. But his discussions e been so guarded by a refusal of admission to those ulative and theoretical explanations, which at best t in the minds of observers themselves as only pro- ilities, that none of his readers need be led into e errors while making them a study.—*The Medical ord*, Feb. 19, 1876.

e revision of this great work has brought it forward the physiological advances of the day, and renders it has ever been, the finest work for students ex- —*Nashville Journ. of Med. and Surg.*, Jan. 1876.

r clearness and perspicuity, Dalton's Physiology mended itself to the student years ago, and was a ant relief from the verbose productions which it planted. Physiology has, however, made many ad- es since then—and while the style has been pre- ed intact, the work in the present edition has been ght up fully abreast of the times. The new chemical tion and nomenclature have also been introduced the present edition. Notwithstanding the multi- y of text-books on physiology, this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent. of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realized. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ.*, Dec. 1875.

We heartily welcome this, the sixth edition of this admirable text book, than which there are none of equal brevity more valuable. It is cordially recommended by the Professor of Physiology in the University of Louisiana, as by all competent teachers in the United States, and wherever the English language is read, this book has been appreciated. The present edition, with its 316 admirably executed illustrations, has been carefully revised and very much enlarged, although its bulk does not seem perceptibly increased.—*New Orleans Medical and Surgical Journal*, March, 1876.

The present edition is very much superior to every other, not only in that it brings the subject up to the times, but that it does so more fully and satisfactorily than any previous edition. Take it altogether it remains in our humble opinion, the best text book on physiology in any land or language.—*The Clinic*, Nov. 6, 1875.

REENE (WILLIAM H.), M.D.,

Demonstrator of Chemistry in Med. Dept, Univ. of Penna.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students. Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages. With illustrations. Cloth, $1 75. (*Just Issued.*)

is well written, and gives the latest views on chemistry, a subject with which most physi- are not sufficiently familiar. To those who wish to improve their knowledge in that direc we can heartily recommend this work as being y of a careful perusal.—*Phila. Med. and Surg. rter*, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit. The descriptions, though brief, are clear, and in most cases sufficient for the purpose. This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

LASSEN (ALEXANDER),

Professor in the Royal Polytechnic School, Aix la-Chapelle.

LEMENTARY QUANTITATIVE ANALYSIS. Translated with notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Just Ready.*)

is probably the best manual of an elementary re extant, insomuch as its methods are the best. aches by examples, commencing with single minations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry. It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

ALLOWAY (ROBERT), F.C.S.,

Prof of Applied Chemistry in the Royal College of Science for Ireland, etc.

A MANUAL OF QUALITATIVE ANALYSIS. From the Fifth London Edition. In one neat royal 12mo. volume, with illustrations; cloth, $2 75. (*Lately Issued.*)

EMSEN (IRA), M.D., Ph.D.,

Professor of Chemistry in the Johns Hopkins University, Baltimore.

PRINCIPLES OF THEORETICAL CHEMISTRY, with special reference to the Constitution of Chemical Compounds. In one handsome royal 12mo. vol. of over 232 pages: cloth, $1 50. (*Just Issued.*)

MAN'S INTRODUCTION TO PRACTICAL EMISTRY, INCLUDING ANALYSIS. Sixth merican, from the sixth and revised London edi- on. With numerous illustrations. In one neat vol., royal 12mo., cloth, $2 25.

OHLER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY. Translated with additions from the ighth German Edition. By IRA REMSEN, M.D., Ph.D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 550 pp, cloth, $3.

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M.D. With illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1200 pages, with 200 illustrations; cloth, $6.

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and

Practical. Revised and corrected by HENRY WATTS, B.A., F R.S., author of "A Dictio ary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illu trations. A new American, from the twelfth and enlarged London edition. Edited ROBERT BRIDGES. M.D. In one large royal 12mo. volume, of over 1000 pag cloth, $2 75; leather, $3 25. (*Just Issued.*)

Two careful revisions by Mr. Watts, since the appearance of the last American editio "Fownes," have so enlarged the work that in England it has been divided into two volumes. reprinting it, by the use of a small and exceedingly clear type, cast for the purpose, it has found possible to comprise the whole, without omission, in one volume, not unhandy for study reference. The enlargement of the work has induced the American Editor to confine his additi to the narrowest compass, and he has accordingly inserted only such discoveries as have been nounced since the very recent appearance of the work in England, and has added the standa in popular use to the Decimal and Centigrade systems employed in the original.

Among the additions to this edition will be found a very handsome colored plate, represent a number of spectra in the spectroscope. Every care has been taken in the typographical exe tion to render the volume worthy in every respect of its high reputation and extended use, though it has been enlarged by more than one hundred and fifty pages, its very moderate p will still maintain it as one of the cheapest volumes accessible to the chemical student.

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more tha thousand pages, but with less than this no fair rep sentation of chemistry as it now is can be given. type is small but very clear, and the sections are lucidly arranged to facilitate study and reference.—*Med and Surg. Reporter*, Aug 3, 1878.

The work is too well known to American stude to need any extended notice; suffice it to say th the revision by the English editor has been faithfu done, and that Professor Bridges has added so fresh and valuable matter, especially in the in ganic chemistry. The book has always been a vorite in this country, and in its new shape b fair to retain all its former *prestige.*—*Boston J of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make remarks relating to the general character of Fo Manual For over twenty years it has held *the* most place as a text-book, and the elaborate thorough revisions which have been made from to time leave little chance for any wide awake ri step before it.—*Canadian Pharm. Jour.*, Aug.

As a manual of chemistry it is without a sup in the language.—*Md. Med. Jour.*, Aug. 1878.

ATTFIELD (JOHN), Ph.D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL, AND PHARMACEUTICA

including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Princ of the Science, and their Application to Medicine and Pharmacy. Eighth edition rev by the author. In one handsome royal 12mo. volume of 700 pages, with illustrati Cloth, $2 50; leather, $3 00. (*Just Ready.*)

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it, little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*Am. Jour. of Pharmacy*, May, 1879.

A standard work like Attfield's Chemistry need only be mentioned by its name, without further comments The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. The author has bestowed arduous labor on the revision, and the extent of the information thus introduced may be estimated from the fact that the index contains three hundred new references relating to additional material.—*Druggists' Circular and Chemical Gazette*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges in United States. The present edition contains alterations and additions as seemed necessary the demonstration of the latest developmen chemical principles, and the latest applicatio chemistry to pharmacy It is scarcely nece for us to say that it exhibits chemistry in its sent advanced state.—*Cincinnati Medical* April, 1879.

The popularity which this work has enjoye owing to the original and clear disposition of facts of the science, the accuracy of the details, the omission of much which freights many trea heavily without bringing corresponding instru to the reader. Dr. Attfield writes for students, primarily for medical students; he always ha eye to the pharmacopœia and its officinal prep tions; and he is continually putting the matter the text so that it responds to the questions which each section is provided. Thus the st learns easily, and can always refresh and te knowledge.—*Med and Surg. Reporter*, April 1

We noticed only about two years and a half the publication of the preceding edition, and marked upon the exceptionally valuable chara of the work. The work now includes the whol the chemistry of the pharmacopœia of the Un States, Great Britain, and India.—*New* May, 1879.

STILLE (ALFRED), M. D., LL.D., and MAISCH (JOHN M.), Ph. D.,
Prof. of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa.
Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready.*)

PREFACE TO THE SECOND EDITION.

The demand which has exhausted in a few months an unusually large edition of the National Dispensatory is doubly gratifying to the authors, as showing that they were correct in thinking that the want of such a work was felt by the medical and pharmaceutical professions, and that their efforts to supply that want have been acceptable. This appreciation of their labors has stimulated them in the revision to render the volume more worthy of the very marked favor with which it has been received. The first edition of a work of such magnitude must necessarily be more or less imperfect; and though but little that is new and important has been brought to light in the short interval since its publication, yet the length of time during which it was passing through the press rendered the earlier portions more in arrears than the later. The opportunity for a revision has enabled the authors to scrutinize the work as a whole, and to introduce alterations and additions wherever there has seemed to be occasion for improvement or greater completeness. The principal changes to be noted are the introduction of several drugs under separate headings, and of a large number of drugs, chemicals, and pharmaceutical preparations classified as allied drugs and preparations under the heading of more important or better known articles: these additions comprise in part nearly the entire German Pharmacopœia and numerous articles from the French Codex. All new investigations which came to the authors' notice up to the time of publication have received due consideration.

The series of illustrations has undergone a corresponding thorough revision. A number have been added, and still more have been substituted for such as were deemed less satisfactory.

The new matter embraced in the text is equal to nearly one hundred pages of the first edition. Considerable as are these changes as a whole, they have been accommodated by an enlargement of the page without increasing unduly the size of the volume.

While numerous additions have been made to the sections which relate to the physiological action of medicines and their use in the treatment of disease, great care has been taken to make them as concise as was possible without rendering them incomplete or obscure. The doses have been expressed in the terms both of troy weight and of the metrical system, for the purpose of making those who employ the Dispensatory familiar with the latter, and paving the way for its introduction into general use.

The Therapeutical Index has been extended by about 2250 new references, making the total number in the present edition about 6000.

The articles there enumerated as remedies for particular diseases are not only those which, in the authors' opinion, are curative, or even beneficial, but those also which have at any time been employed on the ground of popular belief or professional authority. It is often of as much consequence to be acquainted with the worthlessness of certain medicines or with the narrow limits of their power, as to know the well attested virtues of others and the conditions under which they are displayed. An additional value possessed by such an Index is, that it contains the elements of a natural classification of medicines, founded upon an analysis of the results of experience, which is the only safe guide in the treatment of disease.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a *second* edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

FARQUHARSON (ROBERT), M.D.,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA. Second American edition, revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of pages: cloth, $2.25. (*Just Ready.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ. of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodying latest revision of the Pharmacopœia, together w the antidotes to the more prominent poisons, a such of the newer remedial agents as seemed ne sary to the completeness of the work. Tables weights and measures, and a good alphabetical dex end the volume.—*Druggists' Circular Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity w which a second edition is demanded may be t as an indication that the sense of appreciation of value of reliable information regarding the u remedies is not entirely overwhelmed in the cal tion of pathological studies, characteristic of the p sent day. This work certainly merits the succe has so quickly achieved.—*New Remedies*, July,

---

STILLÉ (ALFRED), M.D.,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treat on the Action and Uses of Medicinal Agents, including their Description and Hist Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of about pages. Cloth, $10; leather, $12; half Russia, $18. (*Lately Issued.*)

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct 1875.

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents, Dr. Stillé's is "*par excellence*" the work. The work being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely re issuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg. Journal*, Dec. 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia of t peutics.—*Chicago Medical Journal*, Feb. 187

The rapid exhaustion of three editions and the versal favor with which the work has been re by the medical profession, are sufficient proof excellence as a repertory of practical and usef formation for the physician. The edition bef fully sustains this verdict, as the work has be fully revised and in some portions rewritten, ing it up to the present time by the admis chloral and croton-chloral, nitrite of amyl, ride of methylene, methylic ether, lithium pounds, gelseminum, and other remedies.—*Journ. of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival in multitude of its citations and the fulness of search into clinical histories, and we must a a place in the physician's library; not, inde fully representing the present state of know pharmacodynamics, but as by far the most com treatise upon the clinical and practical side o question.—*Boston Med. and Surg. Journal*, 1874.

GRIFFITH (ROBERT E.), M.D.

A UNIVERSAL FORMULARY, Containing the Methods of Prep ing and Administering Officinal and other Medicines. The whole adapted to Physicians Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by Jo MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In one and handsome octavo volume of about 800 pp., cl., $4 50; leather, $5 50. (*Lately I*

To the druggist a good formulary is simply indispensable, and perhaps no formulary has been more extensively used than the well-known work before us. Many physicians have to officiate, also, as druggists. This is true especially of the country physician, and a work which shall teach him the means by which to administer or combine his remedies in the most efficacious and pleasant manner, will always hold its place upon his shelf. A formulary of this kind is of benefit also to the city physician in largest practice.—*Cincinnati Clinic*, Feb. 21. 1874.

A more complete formulary than it is in its p ent form the pharmacist or physician could ha desire. To the first some such work is indisp ble, and it is hardly less essential to the practi who compounds his own medicines. Much of is contained in the introduction ought to be mitted to memory by every student of medi As a help to physicians it will be found invalu and doubtless will make its way into libraries already supplied with a standard work of the —*The American Practitioner*, Louisville, July

---

CHRISTISON'S DISPENSATORY. With copious additions, and 213 large wood engravings. By R. EGLESFIELD GRIFFITH, M.D. One vol. 8vo., pp. 1000, cloth. $4 00.

CARPENTER'S PRIZE ESSAY ON THE USE ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. edition, with a Preface by D. F. CONDIE, M.D., explanations of scientific words. In one neat volume, pp. 178, cloth. 60 cents.

FLINT (AUSTIN), M.D.,
Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the use of Students and Practitioners of Medicine. Fifth edition, revised and much improved. In one large and closely printed octavo volume of about 1100 pp. (*In press*)

A few notices of the previous edition are appended.

This excellent treatise on medicine has acquired for itself in the United States a reputation similar to that enjoyed in England by the admirable lectures of Sir Thomas Watson. We have referred to many of the most important chapters. and find the revision spoken of in the preface is a genuine one, and that the author has very fairly brought up his matter to the level of the knowledge of the present day. The work has this great recommendation, that it is in one volume, and therefore will not be so terrifying to the student as the bulky volumes which several of our English text-books of medicine have developed into. —*British and Foreign Med.-Chir. Rev.*, Jan. 1875

It is of course unnecessary to introduce or eulogize this now standard treatise. The present edition has been enlarged and revised to bring it up to the author's present level of experience and reading. His own clinical studies and the latest contributions to medical literature both in this country and in Europe, have received careful attention, so that some portions have been entirely rewritten, and about seventy pages of new matter have been added. —*Chicago Med. Jour.*, June, 1873.

Has never been surpassed as a text-book for students and a book of ready reference for practitioners. The force of its logic, its simple and practical teachings, have left it without a rival in the field. *N. Y.—Med. Record*, Sept. 15, 1874.

It is given to very few men to tread in the steps of Austin Flint, whose single volume on medicine, though here and there defective, is a masterpiece of lucid condensation and of general grasp of an enormously wide subject —*Lond. Practitioner*, Dec.'78.

BY THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

It is here that the skill and learning of the great clinician are displayed He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879

The author of the above work has anticipated a want long felt by those for whom it was especially written—the clinical student during his pupilage, and the busy practitioner. He has given to the medical profession a very necessary and useful work, complete in detail, accurate in observation, brief in statement.—*St. Louis Courier of Med.*, Oct 1879.

There is every reason to believe that this book will be well received. The active practitioner is frequently in need of some work that will enable him to obtain information in the diagnosis and treatment of cases with comparatively little labor. Dr. Flint has the faculty of expressing himself clearly, and at the same time so concisely as to enable the searcher to traverse the entire ground of his search, and at the same time obtain all that is essential, without plodding through an interminable space.—*N. Y. Med. Jour.*, Nov. 1879

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*S. Louis Clin. Record*, Oct. 1879.

It is venturing little to say that there are few men so well fitted as Dr. Flint to impart information on these last mentioned subjects, and the present work is a timely one as relates both to the author's capacity to undertake it and the need for it as an accompaniment to the multitude now issued, in which the subject of treatment is but little considered.—*New Remedies*, Nov. 1879.

BY THE SAME AUTHOR.

STURGES'S INTRODUCTION TO THE STUDY OF CLINICAL MEDICINE. Being a Guide to the Investigation of Disease. In one handsome 12mo. volume, cloth, $1 25. (*Lately Issued.*)

CORNIL (V.), *AND* *RANVIER (L.).*

Prof. in the Faculty of Med , Paris. *Prof. in the College of France.*

MANUAL OF PATHOLOGICAL HISTOLOGY. Translated, wi

Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surg to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in U of Penna., and by HENRY C. SIMES. M D., Demonstrator of Pathological Histolog the Univ. of Pa. In one very handsome octavo volume of over 700 pages. with 350 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

The work of Cornil and Ranvier is so well known as a lucid and accurate text-book important subject, that no apology is needed in presenting a translation of it to the Ameri profession. It is only necessary to say that the labors of Drs. Shakespeare and Simes been by no means confined to the task of rendering the work into English. As it appear France, in successive portions, between 1868 and 1876, a part of it, at least, was somewh arrears of the present state of science, while the diffuseness of other portions rendered co sation desirable. The translators have, therefore, sought to bring the work up to the and, at the same time, to reduce it in size, as far as practicable, without impairing its pleteness These changes will be found throughout the volume, the most extensive bei the sections devoted to Sarcoma, Carcinoma, Tuberculosis, the Bloodvessels, the Mamma, the classification of tumors Corresponding modifications have been made in the very ex sive and beautiful series of illustrations, and every care has been taken in the typograp execution to render it one of the most attractive volumes which have issued from the Ameri press.

The translators have done their work very well indeed, rendering it into smooth and excellent English, and in their selection of new material they have in the main used good discrimination. We heartily commend the book as one of the best works on the subject.—*Boston Med. and Surg. Journal*, March 11, 1880.

Their book is not a collection of the work of others, but has been written in the laboratory beside the microscope. It bears the marks of personal knowledge and investigation upon every page, controlled by and controlling the work of others. . . . In short, its translation has made it the best work in pathology attainable in our language, one that every student, certainly, ought to have.—*Archives of Medicine*, April, 1880.

This work, in the original, has for years past occupied a prominent place in the library of French pathologists, as we should naturally be led to believe from the reputation of the distinguished authors. Now that it has been presented to the English student for the first time, it will be perused with unusual interest. The illustrations are b means the least valuable part of the work. I pensable as they are to any work of this in the work before us the artist has succe producing cuts which will prove unusually val to the reader. The translation is well done, gives evidence throughout the volume that it made by a person thoroughly conversant wi subject.—*N. Y. Med. Gazette*, Feb. 28, 1880.

This will be found an exceedingly inte and valuable work by all who are engaged in study of or take an interest in, histology— or morbid. The material which was utilized preparation was derived from autopsies and tions in the hospitals of Paris, which are so rich in it. Nothing was taken for granted everything verified by microscopical investi by the authors themselves in their own labor assisted by their pupils. As an aid to micro in their investigations it will be found invalu in fact, the very best with which we are acqu —*Cincinnati Med. News*, February, 1880.

FENWICK (SAMUEL), M.D.,

Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS. From

Third Revised and Enlarged English Edition. With eighty-four illustrations on w In one very handsome volume, royal 12mo., cloth, $2 25. (*Just Issued.*)

GREEN (T. HENRY), M.D.,

Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School,

PATHOLOGY AND MORBID ANATOMY. Third American, fr

the Fourth and Enlarged and Revised English Edition. In one very handsome volume of 332 pages, with 132 illustrations; cloth, $2 25. (*Now Ready.*)

This is unquestionably one of the best manuals on the subject of pathology and morbid anatomy that can be placed in the student's hands, and we are glad to see it kept up to the times by new editions. Each edition is carefully revised by the author, with the view of making it include the most recent advances in pathology, and of omitting whatever may have become obsolete.—*N. Y. Med. Jour.*, Feb. 1879.

The treatise of Dr. Green is compact, clearly expressed, up to the times, and popular as a text-book, both in England and America. The cuts are sufficiently numerous, and usually well made. In present edition, such new matter has been added was necessary to embrace the later results in pa logical research. No doubt it will continue to the favor it has received at the hands of the pr sion.—*Med and Surg. Reporter*, Feb. 1, 1879.

For practical, ordinary daily use, this is unde edly the best treatise that is offered to stude pathology and morbid anatomy.—*Cincinnati cet and Clinic*, Feb. 8, 1879.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY Translated, with Notes and Additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION: its Disorders and their Treatment. From the second London edition. In one handsome volume, small octavo, cloth, $2 00.

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological, and Therapeutical Relations. In two large and handsome octavo volumes of nearly 1500 pp., cloth. $7 00.

HOLLAND'S MEDICAL NOTES AND REFL TIONS. 1 vol. 8vo., pp. 500, cloth. $3 50.

BARLOW'S MANUAL OF THE PRACTICE MEDICINE. With Additions by D. F. Co M. D. 1 vol. 8vo., pp 600, cloth. $2 50.

TODD'S CLINICAL LECTURES ON CERTAIN A DISEASES. In one neat octavo volume, of cloth. $2 50.

STOKES' LECTURES ON FEVER. Edited by J WILLIAM MOORE, M. D., Assistant Physician to Cork Street Fever Hospital. In one neat volume cloth, $2 00.

REYNOLDS (J. RUSSELL), M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE with Notes and Additions by Henry Hartshorne, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5.00; in sheep, $6.00: half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

Volume I. (*just ready*) contains General Diseases and Diseases of the Nervous System.

Volume II. (*just ready*) contains Diseases of Respiratory and Circulatory Systems.

Volume III. (*just ready*) contains Diseases of the Digestive and Blood Glandular Systems, of the Urinary Organs, of the Female Reproductive System, and of the Cutaneous System.

Reynolds's System of Medicine, recently completed, has acquired, since the first appearance of the first volume, the well-deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as for instance, Diseases of the Bladder by Sir Henry Thompson, Malpositions of the Uterus by Graily Hewitt, Insanity by Henry Maudsley, Consumption by J. Hughes Bennet, Diseases of the Spine by Charles Bland Radcliffe, Pericarditis by Francis Sibson, Alcoholism by Francis E. Anstie, Renal Affections by William Roberts, Asthma by Hyde Salter, Cerebral Affections by H Charlton Bastian, Gout and Rheumatism by Alfred Baring Garrod, Constitutional Syphilis by Jonathan Hutchinson, Diseases of the Stomach by Wilson Fox, Diseases of the Skin by Balmanno Squire, Affections of the Larynx by Morell Mackenzie, Diseases of the Rectum by Blizard Curling, Diabetes by Lauder Brunton, Intestinal Diseases by John Syer Bristowe, Catalepsy and Somnambulism by Thomas King Chambers, Apoplexy by J. Hughlings Jackson, Angina Pectoris by Professor Gairdner, Emphysema of the Lungs by Sir William Jenner, etc. etc. All the leading schools in Great Britain have contributed their best men in generous rivalry, to build up this monument of medical science. St. Bartholomew's, Guy's, St Thomas's, University College, St Mary's in London, while the Edinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical School at Netley, the military and naval services, and the public health boards. That a work conceived in such a spirit, and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have, by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions are required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by Henry Hartshorne, M.D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

Really too much praise can scarcely be given to this noble book. It is a cyclopædia of medicine written by some of the best men of Europe. It is full of useful information such as one finds frequent need of in one's daily work; for no one head can possibly carry all the knowledge one needs in general practice, and one must refer sometimes to one's library. As a book of reference it is invaluable. It is up with the times. It is clear and concentrated in style, and its form is worthy of its famous publisher.—*Louisville Med. News*, Jan. 31, 1880.

"Reynolds' System of Medicine" is justly considered the most popular work on the principles and practice of medicine in the English language. The contributors to this work are gentlemen of well-known reputation on both sides of the Atlantic. Each gentleman has striven to make his part of the work as practical as possible, and the information contained is such as is needed by the busy practitioner.—*St. Louis Med. and Surg. Journ.*, Jan. 20, 1880.

Dr. Hartshorne has made ample additions and revisions, all of which give increased value to the volume, and render it more useful to the American practitioner. There is no volume in English medical literature more valuable, and every purchaser will, on becoming familiar with it, congratulate himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar.—*Gaillard's Med. Journ.*, Feb. 1880.

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,

Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE. Seco American edition, revised by the Author. Edited, with Additions, by JAMES H. Hu INSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half R $6 50. (*Now Ready.*)

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science. The chapter on diseases of the skin and of the nervous system, with a new one on insanity compiled from the best sources outside of the author's own long experience, and the valuable portion relating to general pathology, aid greatly in completing an exceptionally good book for purposes of re and instruction.—*Boston Medical and Su Journal*, February, 1880.

The popularity of the work depends, no d upon the clear and incisive way in which written, and the attention to details likely to in practice, rather than the discussion of qu of theory.—*New Remedies*, Jan. 1880.

What we said of the first edition, we can, increased emphasis, repeat concerning this: " page is characterized by the utterances of a th ful man. What has been said, has been well and the book is a fair reflex of all that is cert known on the subjects considered."—*Ohio Recorder*, Jan. 7, 1880.

RICHARDSON (BENJ. W.), M.D., F.R.S., M.A., LL.D., F.S.A.,

Fellow of the Royal College of Physicians, London.

PREVENTIVE MEDICINE. In one octavo volume of about 500 pa (*In Press.*)

The immense strides taken by medical science during the last quarter of a century have no more conspicuous field of progress than the causation of disease. Not only has this marked advance in therapeutics, but it has given rise to a virtually new department of m cine—the prevention of disease—more important, perhaps, in its ultimate results than eve investigation of curative processes. Yet thus far there has been no attempt to gather i systematic and intelligible shape the accumulation of knowledge thus far acquired on this interesting subject. Fortunately, the task has been at last undertaken by a writer who others is, perhaps, best qualified for its performance, and the result of his labors can hardl to mark an epoch in the history of medical science. The plan adopted for the execution of novel design can best be explained in his own words:—

"With the object here expressed I write this volume. I have nothing to say in it tha any relation to the cure of disease, but I base it nevertheless on the curative side of me learning In other words, I trace the diseases from their actual representation as they before us, in their natural progress after their birth, as far as I am able, back to their ori and try to seek the conditions out of which they spring. Thereupon I endeavor furthe analyze those conditions, to see how far they are removable and how far they are avoidable

WOODBURY (FRANK), M.D.,

Physician to the German Hospital, Philadelphia, late Chief Assist. to Med. Clinic, Jef. C Hospital, etc.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE Medicine; for the use of Students and Practitioners. Based upon Husband's Hand of Practice. In one neat volume, royal 12mo. (*Preparing.*)

HABERSHON (S. O.). M.D.

Senior Physician to and late Lecturer on the Principles and Practice of Medicine at G Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING TH of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, In tines, and Peritoneum. Second American, from the third enlarged and revised lish edition. With illustrations. In one handsome octavo volume of over 500 p Cloth, $3 50. (*Now Ready.*)

FOTHERGILL (J. MILNER), M.D. Edin., M.R.C.P. Lond.,

Asst. Phys. to the West Lond Hosp.; Asst. Phys. to the City of Lond. Hosp., etc.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; Or, Principles of Therapeutics. Second edition, revised and enlarged. In one very octavo volume of about 650 pages. Cloth, $4 00; very handsome half Russia, $ (*Just Ready.*)

The call for a second edition of Dr. Fothergill's work has been met by the author wi revision performed in no perfunctory manner. The entire subject-matter has been submi to a most careful and exhaustive scrutiny, and much new material been added, including arti on "The Functional Disturbances of the Liver," "The Means of Acting on the Respira Nerve Centres," "The Reflex Consequences of Ovarian Irritation," "When Not to G Iron," "Artificial Digestion," etc., thus presenting a complete reflex of the existing condi of therapeutical science.

BY THE SAME AUTHOR.

THE ANTAGONISM OF THERAPEUTIC AGENTS, AND WHA IT TEACHES. Being the Fothergillian Prize Essay for 1878. In one neat volume, re 12mo. of 156 pages; cloth, $1 00. (*Just Ready.*)

EYNOLDS (J. RUSSELL), M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE WITH NOTES AND ADDITIONS BY HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5.00; in sheep, $6.00; half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

UME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.
UME II. (*just ready*) contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.
UME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE CUTANEOUS SYSTEM.

eynolds's SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance he first volume, the well-deserved reputation of being the work in which modern British icine is presented in its fullest and most practical form. This could scarce be otherwise in of the fact that it is the result of the collaboration of the leading minds of the profession, subject being treated by some gentleman who is regarded as its highest authority—as for nce, Diseases of the Bladder by Sir HENRY THOMPSON, Malpositions of the Uterus by LY HEWITT, Insanity by HENRY MAUDSLEY, Consumption by J. HUGHES BENNET, Dis- s of the Spine by CHARLES BLAND RADCLIFFE, Pericarditis by FRANCIS SIBSON, Alcoholism RANCIS E. ANSTIE, Renal Affections by WILLIAM ROBERTS, Asthma by HYDE SALTER, bral Affections by H CHARLTON BASTIAN, Gout and Rheumatism by ALFRED BARING GAR- Constitutional Syphilis by JONATHAN HUTCHINSON, Diseases of the Stomach by WILSON Diseases of the Skin by BALMANNO SQUIRE, Affections of the Larynx by MORELL MAC- IE, Diseases of the Rectum by BLIZARD CURLING, Diabetes by LAUDER BRUNTON, Intes- Diseases by JOHN SYER BRISTOWE, Catalepsy and Somnambulism by THOMAS KING CHAM- , Apoplexy by J. HUGHLINGS JACKSON, Angina Pectoris by Professor GAIRDNER, Emphy- of the Lungs by Sir WILLIAM JENNER, etc. etc. All the leading schools in Great Britain contributed their best men in generous rivalry, to build up this monument of medical sci- . St. Bartholomew's, Guy's, St Thomas's, University College, St Mary's in London, while dinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical ol at Netley, the military and naval services, and the public health boards. That a work eived in such a spirit, and carried out under such auspices should prove an indispensable ury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and success which it has enjoyed in England, and the reputation which it has acquired on this of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations. large size and high price having kept it beyond the reach of many practitioners in this try who desire to possess it, a demand has arisen for an edition at a price which shall ren- accessible to all. To meet this demand the present edition has been undertaken. The olumes and five thousand pages of the original have, by the use of a smaller type and double ns, been compressed into three volumes of over three thousand pages, clearly and hand- ly printed, and offered at a price which renders it one of the cheapest works ever presented e American profession.

t not only is the American edition more convenient and lower priced than the English; also better and more complete. Some years having elapsed since the appearance of a ion of the work, additions are required to bring up the subjects to the existing condition ence. BARTHOLOW (ROBERTS), A.M., M.D., LL.D.

Prof. of Materia Medica and General Therapeutics in the Jeff. Med. Coll. of Phila., etc.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPL

CATION TO MEDICINE. In one very handsome octavo volume of about 45
with illustrations. (*In press.*)

The constantly increasing therapeutic use of electricity, and the absence of a concise
suited to the wants of the general practitioner, have induced the author to prepare the
volume. His object has been to present the most advanced state of existing knowledge
form divested of unnecessary technicalities, keeping constantly in view the practical
the student and physician.

As the volume is founded upon a course of lectures delivered in the Jefferson Medical
during the spring of 1880, its adaptation to its purpose is insured. Dr. Bartholow's power
exposition is well known, and is particularly desirable in a subject such as this, treated
the standpoint of the general practitioner and not of the specialist.

FINLAYSON (JAMES), M.D.,

Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.

CLINICAL DIAGNOSIS; A Handbook for Students and P

titioners of Medicine. In one handsome 12mo. volume, of 546 pages, with 85 ill
tions. Cloth, $2 63. (*Just Issued.*)

The book is an excellent one, clear, concise, convenient, practical. It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan. 4, 1879.

This is one of the really useful books. It is attractive from preface to the final page, and ought
given a place on every office table, because it
in a condensed form all that is valuable in
and diagnostics to be found in bulkier volum
because in its arrangement and complete inde
unusually convenient for quick reference
emergency that may come upon the busy practi
—*N. O. Med. Journ.*, Jan. 1879.

HAMILTON (ALLAN McLANE), M.D.,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island,
and at the Out-Patients' Department of the New York Hospital.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATME

In one handsome octavo volume of 512 pages, with 53 illus.; cloth, $3 50. (*Just I*

CHARCOT (J. M.),

Professor to the Faculty of Med. Paris, Phys. to La Salpêtrière, etc.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM. T

lated from the Second Edition by GEORGE SIGERSON, M.D., M.Ch., Lecturer on B
etc., Cath. Univ. of Ireland. With illustrations. 1 vol. 8vo. of 288 pages. Cloth,
(*Just Ready.*)

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS By C. HANDFIELD JONES. M.D., Physician to St. Mary's Hospital, &c. Second American Edition. In one handsome
volume of 348 pages, cloth, $3 25.

MORRIS (MALCOLM), M.D.,

Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Diagn

Prognosis, Morbid Anatomy, and Treatment. A Manual for Students and Practiti
In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*New R*

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope, there is no book which for clearness of expression and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has pr
a plain, practical book, by aid of which, w
chooses may train his eye to the recogni
light but significant differences. The descri
are neither too vague nor over-refined; the
tions for treatment are clear and succinct.—*L*
Brain, April, 1880.

The author has handled his subject in a cl
concise manner, and as a text-book to stude
manual will be found useful.—*Medical and*
cal Reporter, March 27, 1880.

The author's task has been well done and
duced one of the best recent works upon the
subject of which it treats; there is no work pu
which gives a better view of the elementary
and principles of dermatology.—*New Orle*
cal and Surgical Journal, April, 1880.

This excellent little book is the first wor
distinguished pupil of Jonathan Hutchinson;
commends itself above all by its clearness,
and precision.—*Paris Annales de Dermat*
de Syphiligraphie, 25 April, 1880.

FOX (TILBURY), M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,

Physician to the Department for Skin Diseases, University College Hospital.

EPITOME OF SKIN DISEASES. WITH FORMULÆ. FOR S

DENTS AND PRACTITIONERS. Second edition, thoroughly revised and greatly enlarged
one very handsome 12mo. volume of 216 pages. Cloth, $1 38. (*Just Issued.*)

LINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Hospital Med. College, N. Y.

A MANUAL OF PERCUSSION AND AUSCULTATION; of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism.

Second edition. In one handsome royal 12mo. volume: cloth, $1 63. (*Just Ready.*)

Flint is so well known as a medical teacher writer that it seems superfluous to state that bject has been treated in a thorough and sys manner. In revising it for a second edition thor has confined himself to such additions as likely to render it more useful, not only to ts engaged in the practical study of the subt also to practitioners as a hand book for y reference, and we do not hesitate in saying it would prove a valuable addition to every physician's library.—*Med. and Surg. Reporter*, March 18, 1880.

The little work before us has already become a standard one, and has become extensively adopted as a text-book. There is certainly none better. It contains the substance of the lessons which the author has for many years given, in connection with practical instruction in auscultation and percussion, to private classes, composed of medical students and practitioners.—*Cincinnati Med. News*, Feb. 1880.

THE SAME AUTHOR.

HTHISIS: ITS MORBID ANATOMY, ETIOLOGY, SYMPTOMATIC EVENTS AND COMPLICATIONS, FATALITY AND PROGNOSIS, TREATMENT, AND PHYSICAL DIAGNOSIS; in a series of Clinical Studies.

By AUSTIN FLINT, M D., Prof. of the Principles and Practice of Medicine in Bellevue Hospital Med. College, New York. In one handsome octavo volume: $3 50. (*Lately Issued.*)

THE SAME AUTHOR.

PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate, cloth, $4.

Flint chose a difficult subject for his researches, has shown remarkable powers of observation flection, as well as great industry, in his treatof it. His book must be considered the fullest and clearest practical treatise on those subjects, and should be in the hands of all practitioners and students. It is a credit to American medical literature. —*Amer. Journ. of the Med. Sciences*, July, 1860.

THE SAME AUTHOR.

PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,

Professor of Venereal Diseases at the Col. of Phys. and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL D EASES. Including the results of recent investigations upon the subject. Fourth ed revised and largely rewritten with the co-operation of R. W. Taylor, M.D, of York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half $6 25. (*Just Ready.*)

This work, on its first appearance, immediately took the position of a standard autho its subject wherever the language is spoken, and the success of an Italian translation that it is regarded with equal favor on the Continent of Europe. In repeated editions the labored sedulously to render it more worthy of its reputation, and in the present revis pains have been spared to perfect it as far as possible. Several years having elapsed the publication of the third edition, much material has been accumulated during the in by the industry of syphilologists, and new views have been enunciated. All this so confirmed by observation and experience, has been incorporated; many portions of the been rewritten, the series of illustrations has been enlarged and improved, and the wh be regarded rather as a new work than as a new edition. It is confidently presented as fu a level with the most advanced condition of syphilology, and as a work to which the tioner may refer with the certainty of finding clearly and succinctly set forth whatever within the scope of such a treatise.

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and, we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.—*A of Medicine*, April, 1880.

This now classical work on venereal disea to us in its fourth edition rewritten, enlar materially improved in every way. Dr. Tay we had every reason to expect, has perform part of his work with unusual excellence. that what has been written has done but sca tice to the merits of this truly great treati *Louis Courier of Medicine*, Feb. 1880.

We find that we have here practically a ne —that the statement of the title-page, as to that it has been largely rewritten, is a su modest announcement for the important ch the text. After a thorough examination of sent edition, we can assert confidently that mous labor we have described has been he faithfully and conscientiously performed.— *Journ. Med. Sci.*, Jan. 1880.

It is one of the best general treatises on diseases with which we are acquainted, and cially to be recommended as a guide to the tr of syphilis.—*London Practitioner*, March, 1

CULLERIER (A.), and *BUMSTEAD (FREEMAN J.).*

Surgeon to the Hôpital du Midi.

Professor of Venereal Diseases in the Co Physicians and Surgeons, N. Y

AN ATLAS OF VENEREAL DISEASES. Translated and Edite FREEMAN J. BUMSTEAD. In one large imperial 4to. volume of 328 pages, double-co with 26 plates, containing about 150 figures, beautifully colored, many of them the life; strongly bound in cloth, $17 00; also, in five parts, stout wrappers, at $3 per

Anticipating a very large sale for this work, it is offered at the very low price of THREE LARS a Part, thus placing it within the reach of all who are interested in this depart practice. Gentlemen desiring early impressions of the plates would do well to order it w delay. A specimen of the plates and text sent free by mail, on receipt of 25 cents.

LEE'S LECTURES ON SYPHILIS AND SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. In one handsome octavo volume; cloth, $2 25.

MITH (J. LEWIS), M.D.,

Clinical Professor of Diseases of Children in the Bellevue Hospital Med. College, N Y.

COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Fourth Edition, revised and enlarged. In one handsome octavo volume of about 750 pages, with illustrations. Cloth, $4 50; leather, $5.50; half Russia, $6. (*Now Ready.*)

e very marked favor with which this work has been received wherever the English lan- e is spoken, has stimulated the author, in the preparation of the Fourth Edition, to spare ins in the endeavor to render it worthy in every respect of a continuance of professional ence. Many portions of the volume have been rewritten, and much new matter intro- , but by an earnest effort at condensation, the size of the work has not been materially sed.

he period which has elapsed since the third n of the work, so extensive have been the ad- s that whole chapters required to be rewritten. rdly a page could pass without some material tion or addition. This labor has occupied the r closely, and he has performed it conscien- y, so that the book may be considered a faith- ortraiture of an exceptionally wide clinical ence in infantile diseases, corrected by a care- dy of the recent literature of the subject.—*and Surg. Reporter*, April 5, 1879.

scarcely necessary for us to say the work be- is a standard work upon diseases of children, no work has a higher standing than it upon ffections. In consequence of its thorough re- , the work has been made of more value than nd may be regarded as fully abreast of the We cordially commend it to students and ians. There is no better work in the language ses of children.—*Cincinnati Med. News*, , 1879.

author has evidently determined that it shall e ground in the esteem of the profession for of the latest knowledge on that important ment of medicine. He has accordingly in- rated in the present edition the useful and al results of the latest study and experience, American and *foreign*, especially those bearing rapeutics. Altogether the book has been y improved, while it has not been greatly sed in size.—*New York Medical Journal*, 1879.

This excellent work is so well known that an extended notice at this time would be superfluous. The author has taken advantage of the demand for another new edition to revise in a most careful manner the entire book; and the numerous corrections and additions evince a determination on his part to keep fully abreast with the rapid progress that is being made in the knowledge and treatment of children's diseases. By the adoption of a somewhat closer type, an increase in size of only thirty pages has been necessitated by the new subject matter introduced.—*Boston Med. and Surg. Jour.*, May 29, 1879.

Probably no other work ever published in this country upon a medical subject has reached such a heighth of popularity as has this well-known treatise. As a text and reference-book it is pre-eminently the authority upon diseases of children. It stands deservedly higher in the estimation of the profession than any other work upon the same subject.—*Nashville Journ. of Med. and Surg.*, May, 1879.

The author of this work has acquired an immense experience as physician to three of the large charities of New York in which children are treated. These asylums afford unsurpassed opportunities for observing the effects of different plans of treatment, and the results as embodied in this volume may be accepted with faith, and should be in the possession of all practitioners *now*, in view of the approaching season when the diseases of children always increase. —*Nat Med. Review*, April, 1879.

THOMAS (T. GAILLARD), M.D.,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN.

edition, thoroughly revised and rewritten. In one large and handsome octavo of over 850 pages, with about 270 illustrations. (*In Press.*)

The author has taken advantage of the opportunity afforded by the call for a new edi this work to render it worthy a continuance of the very remarkable favor with which been received. Every portion of the work has been carefully revised, very much of been rewritten, and additions and alterations introduced wherever the advance of scie the increased experience of the author have shown them desirable. At the same time care has been exercised to avoid undue increase in the size of the volume. To accom the numerous additions a more condensed but very clear letter has been used. notwithst which, the number of pages has been increased by more than fifty. The series of illust has been extensively changed; many which seemed to be superfluous have been omitted, large number of new and superior drawings have been inserted. In its improved form, fore, it is hoped that the volume will maintain the character it has acquired of a st authority on every detail of its important subject.

A few notices of the previous edition are appended.

A work which has reached a fourth edition, and that, too, in the short space of five years, has achieved a reputation which places it almost beyond the reach of criticism. and the favorable opinions which we have already expressed of the former editions seem to require that we should do little more than announce this new issue. We cannot refrain from saying that, as a practical work. this is second to none in the English, or. indeed. in any other language. The arrangement of the contents, the admirably clear manner in which the subject of the differential diagnosis of several of the diseases is handled. leave nothing to be desired by the practitioner who wants a thoroughly clinical work. one to which he can refer in difficult cases of doubtful diagnosis with the certainty of gaining light and instruction. Dr. Thomas is a very clear head and decided views. and there be nothing which he so much dislikes as has of diagnosis and blind routine and unreas peutics. The student who will thoroughly book and test its principles by clinical observ certainly not be guilty of these faults.—*Lond* Feb. 13, 1875

Reluctantly we are obliged to close this factory notice of so excellent a work, and i sion would remark that, as a teacher of gyn both didactic and clinical, Prof. Thomas has taken the lead far ahead of his *confrères*, author he certainly has met with unusual lted success.—*Am. Journ. of Obstetrics,*

BARNES (ROBERT), M.D., F.R.C.P.,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SU CAL DISEASES OF WOMEN.

Second American, from the Second Enlarged and English Edition. In one handsome octavo volume, of 784 pages, with 181 illust Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

The call for a new edition of Dr. Barnes's work on the Diseases of Females has the author to make it even more worthy of the favor of the profession than before. By rangement and careful pruning space has been found for a new chapter on the Gynæ Relations of the Bladder and Bowel Disorders, without increasing the size of the boo many new illustrations have been introduced where experience has shown them to be nee is therefore hoped that the volume will be found to reflect thoroughly and accurately the condition of gynæcological science.

Dr Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

We pity the doctor who, having any considerable practice in diseases of women, has no copy of "Barnes" for daily consultation and instruction. It is at once a book of great learning, research, and individual experience, and at the same time eminently practical. That it has been appreciated by the profession, both in Great Britain and in this country, is shown by the second edition following so soon upon the first.—*Am. Practitioner*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 628 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be consulted by the profession.—*Am. Supp Journ. Gt. Britain and Ireland*, Oct. 1878.

No other gynæcological work holds a hig tion, having become an authority every diseases of women. The work has been fully abreast of present knowledge. Every tioner of medicine should have it upon the of his library, and the student will find it a text-book.—*Cincinnati Med. News*, Oct. 18

This second revised edition, of course, des the commendation given to its predecessor. additional one that it appears to include all all the additions to our knowledge of its sub have been made since the appearance of the tion The American references are, for a work, especially full and appreciative, and cordially recommend the volume to Americ ers.—*Journ. of Nervous and Mental Dis* 1878.

This second edition of Dr. Barnes's grea comes to us containing many additions and ments which bring it up to date in every The excellences of the work are too well require enumeration, and we hazard the that they will for many years maintain its sition as a standard text-book and guide students and practitioners.—*N. C. Med.* Oct. 1878.

CHADWICK (JAMES R.), A.M., M.D.

A MANUAL OF THE DISEASES PECULIAR TO WOMEN.

MMET (THOMAS ADDIS), M.D.

Surgeon to the Woman's Hospital, New York, etc.

'HE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thorougly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

e unusually rapid exhaustion of a large edition of this work, while flattering to the author t evidence that his labors have proved acceptable, has in a great measure heightened his of responsibility. He has therefore endeavored to take full advantage of the opportunity ded to him for its revision. Every page has received his earnest scrutiny; the criticisms reviewers have been carefully weighed; and while no marked increase has been made in ke of the volume, several portions have been rewritten, and much new matter has been l. In this minute and thorough revision, the labor involved has been much greater than haps apparent in the results, but it has been cheerfully expended in the hope of rendering ork more worthy of the favor which has been accorded to it by the profession.

o country of the world has gynæcology re- l more attention than in America. It is, then, feeling of pleasure that we welcome a work eases of women from so eminent a gynæcolo Dr. Emmet, and the work is essentially clini- d leaves a strong impress of the author's in- ality. To criticize, with the care it merits, k throughout, would demand far more space at our command. In parting, we can say work teems with original ideas, fresh and le methods of practice, and is written in a d elegant style, worthy of the literary repu- of the country of Longfellow and Oliver Wen- lmes.—*Brit. Med. Journ*, Feb. 21, 1880.

ynæcological treatise has appeared which s an equal amount of original and useful ; nor does the medical and surgical history rica include a book more novel and useful. bular and statistical information which it ns is marvellous, both in quantity and accu- and cannot be otherwise than invaluable to investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med. Gaz.*, April 5, 1880

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

NCAN (J. MATTHEWS), M.D., LL.D., F.R.S.E., etc.

LINICAL LECTURES ON THE DISEASES OF WOMEN, **Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 pages. Cloth, $1 50.** (*Just Ready.*)

are in every way worthy of their author; we look upon them as among the most valu- his contributions They are all upon mat- great interest to the general practitioner f them deal with subjects that are not, as a dequately handled in the text-books; others , while bearing upon topics that are usually of at length in such works, yet bear such a f individuality that, if widely read, as they ly deserve to be, they cannot fail to exert a ome restraint upon the undue eagerness with many young physicians seem bent upon fol- the wild teachings which so infect the gynæ- of the present day.—*N. Y. Med. Journ.*, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

MSBOTHAM (FRANCIS H.), M.D.

HE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDI-
INE AND SURGERY, in reference to the Process of Parturition. A new and enlarged dition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., rofessor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large nd handsome imperial octavo volume of 650 pages, strongly bound in leather, with raised ands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00.

INCKEL (F.),

Professor and Director of the Gynæcological Clinic in the University of Rostock.

COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED, **for Students and Practitioners. Translated, with the consent of the author, from the Second German Edition, by JAMES READ CHADWICK, M.D. In one octavo volume. Cloth, $4 00.** (*Lately Issued.*)

NNER (THOMAS H.), M.D.

ON THE SIGNS AND DISEASES OF PREGNANCY. **First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.**

GROSS (SAMUEL D.), M.D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic,

and Operative. Illustrated by upwards of Fourteen Hundred Engravings Fifth edition carefully revised, and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

The continued favor, shown by the exhaustion of successive large editions of this great work, proves that it has successfully supplied a want felt by American practitioners and students. In the present revision no pains have been spared by the author to bring it in every respect fully up to the day. To effect this a large part of the work has been rewritten, and the whole enlarged by nearly one-fourth, notwithstanding which the price has been kept at its former very moderate rate. By the use of a close, though very legible type, an unusually large amount of matter is condensed in its pages, the two volumes containing as much as four or five ordinary octavos. This, combined with the most careful mechanical execution, and its very durable binding renders, it one of the cheapest works accessible to the profession. Every subject properly belonging to the domain of surgery is treated in detail, so that the student who possesses this work may be said to have in it a surgical library.

We have now brought our task to a conclusion, and have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together. that the busy practitioner, when in difficulty, can at once find the information he requires. His work, on the contrary, is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced. and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 180, but. the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares.*" It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid. instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition, and arrangement of acquired knowledge and personal experience.—*N.Y. Med. Journ.*, Feb. 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor.and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES,

and Malformations of the Urinary Bladder, the Prostate Gland, and the Urethra. Third Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with 170 illustrations: cloth, $4 50. (*Just Issued.*)

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct 1876.

It is with pleasure we now again take up this old work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture" is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE

AIR-PASSAGES. In 1 vol. 8vo., with illustrations, pp. 468, cloth, $2 75.

DRUITT (ROBERT), M.R.C.S., &c.

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY.

A new and revised American, from the eighth enlarged and improved London edition Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

All that the surgical student or practitioner could desire.—*Dublin Quarterly Journal.*

It is a most admirable book. We do not know when we have examined one with more pleasure.—*Boston Med. and Surg. Journal.*

In Mr. Druitt's book, though containing only some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic We have examined the book most thoroughly, and can say that this success is well merited. His book moreover, possesses the inestimable advantages of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Sciences.*

ASHHURST (JOHN, Jr.), M.D.,

Prof. of Clinical Surgery, Univ of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY. Second

edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7.50 (*Just Ready.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

The attempt to embrace in a volume of 1000 pages the whole field of surgery, general and special, would be a hopeless task unless through the most tireless industry in collating and arranging, and the wisest judgment in condensing and excluding. These facilities have been abundantly employed by the author, and he has given us a most excellent treatise, brought up by the revision for the second edition to the latest date. Of course this book is not designed for specialists, but as a course of general surgical knowledge and for general practitioners, and as a text-book for students it is not surpassed by any that has yet appeared, whether of home or foreign authorship.—*N. Carolina Med. Journal*, Jan. 1879.

Ashhurst's Surgery is too well known in this country to require special commendation from us. This, its second edition, enlarged and thoroughly revised, brings it nearer our idea of a model text-book than any recently published treatise. Though numerous additions have been made, the size of the work is not materially increased. The main trouble of text books of modern times is that they are too cumbersome. The student needs a book which will furnish him the most information in the shortest time. In every respect this work of Ashhurst is the model text-book - full, comprehensive and compact.—*Nashville Jour. of Med. and Surg.*, Jan. '79.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

BRYANT (THOMAS), F.R.C.S.,

Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY. Second American, from the Second and Revised English Edition.

With Six Hundred and Seventy-two Engravings on Wood. In one large and very handsome imperial octavo volume of over 1000 large and closely printed pages. Cloth, $6; leather, $7. (*Just Ready.*)

This work has enjoyed the advantage of two thorough revisions at the hand of the author since the appearance of the first American edition, resulting in a very notable enlargement of size and improvement of matter. In England this has led to the division of the work into two volumes, which are here comprised in one, the size being increased to a large imperial octavo, printed on a condensed but clear type. The series of illustrations has undergone a like revision, and will be found correspondingly improved.

The marked success of the work on both sides of the Atlantic shows that the author has succeeded in the effort to give to student and practitioner a sound and trustworthy guide in the practice of Surgery; while the simultaneous appearance of the present edition in England and in this country affords to the American reader the benefit of the most recent advances made abroad in surgical science.

There are so many text-books of surgery, so many written by skilled and distinguished hands, that to obtain the honor of a third edition in England is no light praise. Mr. Bryant merits this, by clearness of style, and good judgment in selecting the operations he recommends, in his new editions he goes carefully over the old grounds, in light of later research. On these and many allied points, Mr. Bryant is a calm and unpartisan observer, and his book throughout has the great merit of maintaining the true scientific, judicial tone of mind.—*Med. and Surg. Reporter*, March 22, 1879.

The work before us is the American reprint of the last London edition, and has the advantage over the latter in being of more convenient size, and in being compressed into one volume. The author has rewritten the greater part of the work, and has succeeded, in the amount of new matter added, in making it markedly distinctive from previous editions. A few extra pages have been added, and also a few new illustrations introduced. The publishers have presented the work in a creditable style. As a concise and practical manual of British surgery it is perhaps without an equal, and will doubtless always be a favorite text-book with the student and practitioner.—*N. Y. Med. Record*, March 22, 1879.

Another edition of this manual having been called for, the author has availed himself of the opportunity to make no few alterations in the substance as well as in the arrangement of the work, and, with a view to its improvement, has recast the materials and revised the whole. We ourselves are of the opinion that there is no better work on surgery extant.—*Cincinnati Med. News*, March, 1879

Bryant's Surgery has been favorably received from the first, and evidently grows in the esteem of the profession with each succeeding edition. In glancing over the volume before us we find proof in almost every chapter of the thorough revision which the work has undergone, many parts having been cut out and replaced by matter entirely fresh.—*N. Y. Med. Journ.*, April, 1879.

Welcome as the new edition is, and as much as it is entitled to commendation, yet its appearance at this time is, in a certain sense, a matter of regret, as it will be in competition with another work, lately issued from the same press. But, the difficult task of forming a judgment as to the relative merits of Bryant and Ashhurst we will not attempt, but predict that, considering the high excellence of both, many others will likewise be forced to hesitate long in making choice between them.—*Cincinnati Lancet and Clinic*, March 22, 1879.

ERICHSEN (JOHN E.),

Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise on gical Injuries, Diseases, and Operations. Carefully revised by the author fr Seventh and enlarged English Edition. Illustrated by eight hundred and sixty gravings on wood. In two large and beautiful octavo volumes of nearly 2000 cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

In revising this standard work the author has spared no pains to render it worthy of a ance of the very marked favor which it has so long enjoyed, by bringing it thorou level with the advance in the science and art of surgery made since the appearance last edition. To accomplish this has required the addition of about two hundred page while the illustrations have undergone a marked improvement. A hundred and fifty ad wood-cuts have been inserted, while about fifty other new ones have been substituted for which were not deemed satisfactory. In its enlarged and improved form it is theref sented with the confident anticipation that it will maintain its position in the front text-books for the student, and of works of reference for the practitioner, while its exce moderate price places it within the reach of all.

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science. We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am. Practitioner*, April, 1878.

It is no idle compliment to say that this is the best edition Mr. Erichsen has ever produced of his well-known book. Besides inheriting the virtues of its predecessors, it possesses excellences quite its own. Having stated that Mr. Erichsen has incorporated into this edition every recent improvement in the science and art of surgery, it would be a supererogation to give a detailed criticism. In short, we unhesitatingly aver that we know of no other single work where the student and practitioner can gain at once so clear an insight into the principles of surgery, and so complete a knowledge of the exigencies of surgical practice.—*London Lancet*, Feb. 14, 1878

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

Of the many treatises on Surgery which it our task to study, or our pleasure to read, the which in all points has satisfied us so well as treatise of Erichsen. His polished, clear style, dom from prejudice and hobbies, his unsurp of his subject, and vast clinical experience, q admirably to write a model text-book. Whe at the least cost of time, to learn the most of surgery, we turn, by preference, to his work. pleasure, therefore, to see that the apprecia general, and has led to the appearance of an tion.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, wee much old matter has been omitted. The has been thoroughly written up, and not mere ed by a few extra chapters. A great improv been made in the illustrations. One hundre new ones have been added, and many of the have been redrawn. The author highly app favor with which his work has been received by can surgeons, and has endeavored to render edition more than ever worthy of their app he has succeeded admirably, must, we thi general opinion. We heartily recommend t both student and practitioner.—*N. Y. Med.* Feb. 1878.

Erichsen has stood so prominently fo years as a writer on Surgery, that his rep world wide, and his name is as familiar to ical student as to the accomplished and ex surgeon. The work is not a reprint of f tions, but has in many places been entire ten. Recent improvements in surgery ha caped his notice, various new operations thoroughly analyzed, and their merits t discussed. One hundred and fifty new add to the value of this work.—*N. O. Med. Journal*, March, 1878.

HOLMES (TIMOTHY), M.D.,

Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE. In one some octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; lea half Russia, $7 50. (*Just Issued.*)

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Reco* 14, 1876.

It will be found a most excellent epito gery by the general practitioner who has time to give attention to more minute and works and to the medical student. In fact, of no one we can more cordially recomme author has succeeded well in giving a p practical account of each surgical injury ease, and of the treatment which is mo monly advisable. It will no doubt become lar work in the profession, and especially book.—*Cincinnati Med. News*, April, 1876.

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the fourth and enlarged London Edition. With illustrations. In one 8vo. vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTHER TIONS OF MINOR SURGERY. New editi an additional chapter on Military Surger 12mo. vol. of 383 pages with 184 wood-cuts. $1 75.

HAMILTON (FRANK H.), M.D.,

Professor of Fractures and Dislocations, &c., in Bellevue Hosp. Med. College, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. Fifth edition, revised and improved. In one large and handsome octavo volume of nearly 800 pages, with 344 illustrations. Cloth, $5 75; leather, $6 75. (*Lately Issued.*)

WELLS (J. SOELBERG),

Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American, from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates. Together with selections from the Test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. (*In Press.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

NETTLESHIP (EDWARD), F.R.C.S.,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

MANUAL OF OPHTHALMIC MEDICINE. In one royal 12mo. volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The book is written in a careful and logical manner, and though extremely concise, we have failed to notice any evidence of ambiguity. It is rendered more compact and homogeneous by frequent references, by page number, to other portions of the work; repetitions are thus avoided, and we have been surprised to find how much information our author has succeeded in conveying in so small a space. A careful study of the book will well repay the general practitioner, even though it should serve only as a *monitor*. It is particularly useful in the latter regard, as the subject of treatment is presented in a thoroughly conservative manner.—*N. Y. Med. Record*, March 6, 1880.

The author has succeeded in touching upon about all the points, operations, diseases of the eye in relation to general diseases, and has prepared a very acceptable book.—*Cincinnati Lancet and Clinic*, Feb. 7, 1880.

It is *multum in parvo*, containing all the leading points to be remembered in the pathology, description, and treatment of diseases of the eye. It will be found especially valuable in preparing for examinations Practitioners will find it convenient as a work of reference, when they wish to refresh their memories in respect to the features of some affections.—*Cincinnati Med. News*, Jan 1880.

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

A careful examination has convinced us that it is the best work of its class that has come to our notice. While all matter is condensed to the utmost, there are few points that are obscured thereby, and all are rendered really attractive to the average student. We can only hope that every medical student shall be compelled to master the entire volume ere receiving his degree. General practitioners who take care of eye cases would do well to refresh their memories by its careful study.—*Detroit Lancet*, April, 1880.

CARTER (R. BRUDENELL), F.R.C.S.,

Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE. Edited, with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75. (*Just Issued.*)

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (EDGAR A.),

Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE. Being Elementary Instructions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1. (*Now Ready.*)

LAURENCE'S HANDY BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged With numerous illustrations. In one very handsome octavo volume cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT, AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth $3 50.

BURNETT (CHARLES H.), M.A , M.D.,

Aural Surg to the Presb. Hosp., Surgeon-in-charge of the Infir for Dis. of the Ear, Phi

THE EAR, ITS ANATOMY, PHYSIOLOGY, AND DISEAS

A Practical Treatise for the Use of Medical Students and Practitioners. In one h some octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; lea $5 50; half Russia, $6 00. (*Now Ready.*)

Recent progress in the investigation of the structures of the ear, and advances made i modes of treating its diseases, would seem to render desirable a new work in which all t sources of the most advanced science should be placed at the disposal of the practitioner. it has been the aim of Dr. Burnett to accomplish, and the advantages which he has enjoy the special study of the subject are a guarantee that the result of his labors will prove of se to the profession at large, as well as to the specialist in this department.

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Tröltsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work, which as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well rep busy practitioner in the pleasure he will derive the agreeable style in which many otherwi and mostly unknown subjects are treated. T specialist the work is of the highest value, a sense of gratitude to Dr. Burnett will we hop proportionate to the amount of benefit he can d from the careful study of the book, and a con reference to its trustworthy pages.—*Edin Med. Jour.*, Aug. 1878.

The book is designed especially for the use o dents and general practitioners, and places at disposal much valuable material. Such a b the present one, we think, has long been neede we may congratulate the author on his succ filling the gap. Both student and practitio study the work with a great deal of benefit. profusely and beautifully illustrated.—*N. Y pital Gazette*, Oct 15, 1877.

Dr. Burnett is to be commended for having w the best book on the subject in the English la and especially for the care and attention b given to the scientific side of the subject.—*A Med. Journ.*, Dec. 1877.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE A MEDICINE.

Third American, from the Third and Revised English Edition. I large octavo volume of 850 pages; cloth, $5 50; leather, $6 50. (*Just Issued.*)

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal inv tions.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the comp of this volume, stores of learning, experience practical acquaintance with his subject, prob beyond what any other living authority on to ogy could have amassed or utilized. He has sustained his reputation by the consummate and legal acumen he has displayed in the ar ment of the subject-matter, and the result is a on Poisons which will be indispensable to eve dent or practitioner in law and medicine.—*Th lin Journ. of Med. Sci.*, Oct. 1875.

BY THE SAME AUTHOR.

MEDICAL JURISPRUDENCE. Seventh American Edition. Ed

by John J. Reese, M.D., Prof. of Med. Jurisp. in the Univ. of Penn. In one octavo volume of nearly 900 pages. Cloth, $5 00; leather, $6 00. (*Lately Iss*

To the members of the legal and medical profession, it is unnecessary to say anything commendatory of Taylor's Medical Jurisprudence. We might as well undertake to speak of the merit of Chitty's Pleadings.—*Chicago Legal News*, Oct. 16, 1873.

It is beyond question the most attractive as well as most reliable manual of medical jurisprudence published in the English language.—*Am. Journal of Syphilography*, Oct. 1873.

It is altogether superfluous for us to offer anything in behalf of a work on medical jurisprudence by an author who is almost universally esteemed to be the best authority on this specialty in our langua this point, however, we will say that we consid Taylor to be the safest medico-legal authority t low, in general, with which we are acquainted i language.—*Va. Clin. Record*, Nov. 1873.

This last edition of the Manual is probably th of all, as it contains more material and is wr to the latest views of the author as expressed i last edition of the Principles. Dr. Reese, the e of the Manual, has done everything to mak work acceptable to his medical countrymen.—*Med. Record*, Jan. 15, 1874.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISP DENCE.

Second Edition, Revised, with numerous Illustrations. In two large volumes, cloth, $10 00; leather, $12 00

This great work is now recognised in England as the fullest and most authoritative treati very department of its important subject. In laying it, in its improved form, before the A ican profession, the publishers trust that it will assume the same position in this country.

OBERTS (WILLIAM), M.D.,

Lecturer on Medicine in the Manchester School of Medicine, etc.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

HOMPSON (SIR HENRY),

Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25. (*Just Issued.*)

THE SAME AUTHOR.

N THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50. (*Lately Published.*)

UKE (DANIEL HACK), M.D.,

Joint author of "The Manual of Psychological Medicine," &c.

LLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25. (*Lately Issued.*)

LANDFORD (G. FIELDING), M.D., F.R.C.P.,

Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

NSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

atisfies a want which must have been sorely y the busy general practitioners of this country. es the form of a manual of clinical description various forms of insanity, with a description mode of examining persons suspected of in- y. We call particular attention to this feature book, as giving it a unique value to the gene- ctitioner. If we pass from theoretical conside- s to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

A (HENRY C.).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL, AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

s valuable work is in reality a history of civi- n as interpreted by the progress of jurispru- . . . . In "Superstition and Force" we have losophic survey of the long period intervening een primitive barbarity and civilized enlight- nt. There is not a chapter in the work that ld not be most carefully studied, and however versed the reader may be in the science of udence, he will find much in Mr. Lea's vol- of which he was previously ignorant. The is a valuable addition to the literature of l science.—*Westminster Review*, Jan. 1880.

e appearance of a new edition of Mr. Henry C. 's "Superstition and Force" is a sign that our est scholarship is not without honor in its na- country. Mr. Lea has met every fresh demand is work with a careful revision of it, and the nt edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

THE SAME AUTHOR. (*Lately Published.*)

STUDIES IN CHURCH HISTORY—THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75.

he story was never told more calmly or with ter learning or wiser thought. We doubt, indeed, y other study of this field can be compared with for clearness, accuracy, and power.—*Chicago miner*, Dec. 1870.

r. Lea's latest work, "Studies in Church History," ly sustains the promise of the first. It deals with ee subjects—the Temporal Power, Benefit of ergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

OXAM'S CHEMISTRY. In one 8vo. vol. of 700 pp., with 300 illustrations. Cloth, $4; leather, $5.
OWES' CHEMISTRY. In one 12mo. vol. of 372 pages, with about 50 illus. Cloth, $2 50.
ENE'S MANUAL OF MEDICAL CHEMISTRY. In one 12mo. vol. of 312 pp., with illus. Cl. $1.75.

MATERIA MEDICA AND THERAPEUTICS.

ILLÉ AND MAISCH'S NATIONAL DISPENSATORY. Second ed. In one handsome 8vo. vol. of 1692 pages, with 239 illus. Extra cloth, $6.75; leather, $7.50; half Russia, raised bands, open back, $8.25.
ILLÉ'S THERAPEUTICS AND MATERIA MEDICA. In two large 8vo. volumes of about 2000 pages. Cloth, $10; leather, $12; half Russia, $13.
UCHARSON'S THERAPEUTICS AND MATERIA MEDICA. In one 12mo. vol. of 498 pp. Cl. $2.25.
FFITH'S UNIVERSAL FORMULARY. In one 8vo. vol. of 779 pp. Cloth, $4.50; leather, $5.50
RISH'S PHARMACY. In one vol. of 977 pp., with 280 illus. Cl. $5.50; leather, $6.50; half Russia, $7.

PATHOLOGY.

NIL AND RANVIER'S PATHOLOGICAL HISTOLOGY. In one octavo volume of over 700 pages, with 350 illustrations. Cloth, $5.50; leather, $6.50; half Russia, $7.
EN'S PATHOLOGY AND MORBID ANATOMY. In one 8vo. vol. of 332 pp., with 132 illus. Cl. $2.25.

PRACTICE.

NT'S PRACTICE. New edition. In one octavo volume of about 1100 pages. (*In press.*)
NT'S CLINICAL MEDICINE. In one 8vo. vol. of 795 pp. Cl. $4 50; leather, $5.50; half Russia, $6.
STOWE'S TREATISE ON THE PRACTICE OF MEDICINE. In one octavo volume of nearly 1200 pages, with illustrations. Cloth, $5; leather, $6; half Russia, $6.50.
HERGILL'S HANDBOOK OF TREATMENT. In one 8vo. vol. of 650 pp. Cl. $4; half Russia, $5.50.
TSHORNE'S ESSENTIALS. In one 12mo. vol. of 548 pp., with 100 illus. Cl. $2.63; half bound, $2.88.
STEAD ON VENEREAL DISEASES. In one royal 12mo. volume of 835 pages, with 138 illustrations. Cloth, $4.75; leather, $5.75; half Russia, $6.25.

DISEASES OF WOMEN AND CHILDREN.

MAS'S PRACTICAL TREATISE ON THE DISEASES OF WOMEN. New edition. In one octavo volume of over 850 pages, with about 270 illustrations. (*In press.*)
ST'S PRINCIPLES AND PRACTICE OF GYNÆCOLOGY. In one octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, $6.50.
NES ON WOMEN. In one 8vo. vol. of 784 pp., with 181 illust Cl. $4.50; leather, $5 50; half Russia, $6.
TH'S COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. In one octavo volume of 750 pages, with illustrations. Cloth, $4.50; leather, $5.50; half Russia, $6.

MIDWIFERY.

SHMAN'S SYSTEM OF MIDWIFERY. In one octavo volume of 733 pages, with over 200 illustrations. Cloth, $4.50; leather, $5.50; half Russia, $6.
YFAIR'S TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY. In one octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5.50.
SBOTHAM'S OBSTETRICS. In one imp. 8vo. vol. of 650 pp.; many plates and illus. Leather, $7.
NES'S MANUAL OF MIDWIFERY. In one 12mo. vol. of 200 pp., with 50 illus. Cloth, $1.25.

SURGERY.

OSS'S SYSTEM OF SURGERY. In two imp. 8vo. vols. of 2268 pages, with 1400 illus. Leather, $15; half Russia, $16.
HURST'S PRINCIPLES AND PRACTICE OF SURGERY. In one 8vo. volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7 50.
ANT'S PRACTICE OF SURGERY. In one imperial 8vo. volume of over 1000 pages, with 672 illustrations. Cloth, $6; leather, $7; half Russia, $7.50.
CHSEN'S SCIENCE AND ART OF SURGERY. In two 8vo. volumes of nearly 2000 pages, with 862 illustrations. Cloth, $8.50; leather, $10.50; half Russia, $11 50.
LMES'S SURGERY. In one 8vo. vol. of nearly 1000 pages, with 411 illus. Cl. $6; leat $7; hf. Rus. $7.50.
SON'S MANUAL OF OPERATIVE SURGERY. In one 12mo vol. of 477 pp, with 332 illus. Cl $2.50.
MILTON'S TREATISE ON FRACTURES AND DISLOCATIONS. In one octavo volume of nearly 800 pages, with 344 illustrations. Cloth, $5.75; leather, $6.75.

DISEASES OF THE EYE AND EAR.

LLS ON DISEASES OF THE EYE. In one 8vo. vol. of 900 pp, with 250 illus. (*In press*)
TLESHIP ON THE EYE In one 12mo. vol. of 369 pp., with 89 illus. Cloth, $2.
RTER ON DISEASES OF THE EYE. In one 8vo. vol. of 500 pp., with 124 illus. Cl. $3.75.
RNETT ON THE EAR. In one 8vo. vol. of 615 pp., with 87 illus. Cl. $4 50; leat. $5.50; half Russia, $6.

MEDICAL JURISPRUDENCE.

YLOR'S MEDICAL JURISPRUDENCE In one 8vo. volume of nearly 900 pages. Cloth, $5; leather, $6.
YLOR ON POISONS. In one 8vo. volume of 850 pages. Cloth, $5.50; leather, $6.50.

MANUALS.

NGLISON'S MEDICAL LEXICON. In one 8vo. vol. of 1131 pages. Cl. $6 50; leather, $7.50; hf Rus. $8.
ARTSHORNE'S CONSPECTUS OF THE MEDICAL SCIENCES. In one 12mo. volume of over 1000 pages, with 477 illustrations. Cloth, $4.25; leather, $5.
DLOW'S MANUAL. In one 12mo. vol. of 816 pp., with 370 illus. Cloth, $3 25; leather, $3.75.

HENRY C. LEA'S SON & CO., Philadelphia.

NOTICE TO SUBSCRIBERS.

INCREASED INDUCEMENTS FOR 1880.

With a view of increasing the attractions of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," and of bringing within the reach of all members of the profession the immense amount of information now presented by it and its accessory periodicals, the "MEDICAL NEWS AND LIBRARY" and the "MONTHLY ABSTRACT," the two latter will hereafter be merged together, under the name of "THE MEDICAL NEWS AND ABSTRACT," commencing January 1, 1880. The "NEWS AND ABSTRACT" will consist of sixty-four pages per month, handsomely printed, in a neat cover, and will contain all the material heretofore presented in both periodicals, with the exception of the sixteen pages of the "Library Department." Its price will be TWO DOLLARS AND A HALF per annum, invariably in advance, at which rate subscribers will receive nearly *eight hundred large octavo pages per annum,* free of postage.

Not only will this monthly thus be in itself one of the cheapest periodicals offered to the profession, but it will be furnished in commutation, without charge, to advance-paying subscribers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," the subscription to which will remain, as heretofore, FIVE DOLLARS per annum. For this very moderate sum, therefore, subscribers will receive two periodicals of the highest class, a Quarterly and a Monthly, containing in all nearly two thousand pages per annum, stored with the choicest original and selected matter that can be furnished by the medical literature of both hemispheres.

These terms may be recapitulated as follows:—

TERMS FOR 1880.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),	**Five Dollars per annum, in advance.**

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance.	**Five Dollars.**

The MEDICAL NEWS AND ABSTRACT, invariably in advance, **Two Dollars and a Half.**

⁂ Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

It is evident that only a very considerable increase to the existing subscription list will justify the unexampled terms thus offered, by which the equivalent of three or four large octavo volumes is furnished, handsomely printed in a form for preservation, for the trifling sum of FIVE DOLLARS. Gentlemen, therefore, are respectfully requested to lose no time in remitting their subscriptions, to avoid the risk of disappointment from the exhaustion of the edition printed; and it is suggested that they may aid in rendering the enterprise permanent by kindly communicating to their friends the very great inducements thus offered.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

THE

MEDICAL NEWS

AND

ABSTRACT.

A CONSOLIDATION OF THE "MEDICAL NEWS AND LIBRARY" AND THE "MONTHLY ABSTRACT OF MEDICAL SCIENCE."

EDITED BY

I. MINIS HAYS, A.M., M.D.

PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1880.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1880, by HENRY C. LEA'S SON & Co., in the Office of the Librarian of Congress. All rights reserved.

MEDICAL AND SURGICAL TEXT-BOOKS.

ANATOMY.

GRAY'S ANATOMY Descriptive and Surgical. In one imperial octavo volume of nearly 1000 pages, with 522 large illustrations. Cloth, $6; leather, $7; half Russia, $7.50.

WILSON'S SYSTEM OF HUMAN ANATOMY. In one 8vo. vol. of 616 pp. Cl. $4; leather, $5.

ELLIS'S DEMONSTRATIONS OF ANATOMY. In one 8vo. vol. of 716 pp., with 256 illus. Cloth, $4.25; leather, $5.25.

SMITH AND HORNER'S ANATOMICAL ATLAS. In one imp. 8vo. vol., with 650 illus. Cl. $4.50.

PHYSIOLOGY.

DALTON'S PHYSIOLOGY. In one octavo volume of 825 pages, with 316 illustrations. Cloth, $5.50; leather, $6.50; half Russia, $7.

CARPENTER'S PRINCIPLES OF HUMAN PHYSIOLOGY. In one octavo volume of 1083 pages, with 373 illustrations. Cloth, $5.50; leather, $6.50; half Russia, $7.00.

FOSTER'S TEXT-BOOK OF PHYSIOLOGY, with American notes. In one royal 12mo. volume of 1030 pages, with 259 illustrations. Cloth, $1.50; leather, $2.

CHEMISTRY.

FOWNES'S CHEMISTRY. In one large 12mo. vol. of over 1000 pp., with 177 illus. Cloth, $2.75; leather, $3.25.

ATTFIELD'S CHEMISTRY. In one large 12mo. volume of 700 pages, with illustrations. Cloth, $2.50; leather, $3.

BLOXAM'S CHEMISTRY. In one 8vo. volume of 700 pages, with 300 illustrations. Cloth, $4; leather, $5.

CLOWES'S CHEMISTRY. In one 12mo. vol. of 372 pages, with about 50 illus. Cloth, $2 50.

GREENE'S MANUAL OF MEDICAL CHEMISTRY. In one 12mo. vol. of 312 pages, with illustrations. Cloth, $1.75.

MATERIA MEDICA AND THERAPEUTICS.

STILLÉ AND MAISCH'S NATIONAL DISPENSATORY. Second edition. In one handsome 8vo. volume of 1692 pages, with 239 illustrations. Extra cloth, $6.75; leather, $7.50; half Russia, raised bands, $8.25.

STILLÉ'S THERAPEUTICS AND MATERIA MEDICA. In two large 8vo. volumes of about 2000 pages. Cloth, $10; leather, $12; half Russia, $13.

FARQUHARSON'S THERAPEUTICS AND MATERIA MEDICA. In one 12mo. vol. of 498 pages. Cloth, $2.25.

GRIFFITH'S UNIVERSAL FORMULARY. In one 8vo. vol. of 779 pages. Cloth, $4.50; leather, $5.50.

PARRISH'S PHARMACY. In one vol. of 977 pages, with 280 illustrations. Cloth, $5.50; leather, $6.50; half Russia, $7.

PATHOLOGY.

CORNIL AND RANVIER'S PATHOLOGICAL HISTOLOGY. In one octavo volume of over 700 pages, with 350 illustrations. Cloth, $5.50; leather, $6.50; half Russia, $7.

GREEN'S PATHOLOGY AND MORBID ANATOMY. In one 8vo. volume of 332 pages, with 132 illustrations. Cloth, $2.25.

PRACTICE.

FLINT'S PRACTICE. New edition. In one octavo volume of about 1100 pages. (*In press.*)

FLINT'S CLINICAL MEDICINE. In one 8vo. volume of 795 pages. Cloth, $4.50; leather, $5.50; half Russia, $6.

REYNOLDS'S SYSTEM OF MEDICINE, with notes and additions by Henry Hartshorne, M.D. In three very large 8vo. volumes of 3052 pages, with about 350 illustrations. (*Sold only by subscription.*) Cloth, $15; leather, $18; half Russia, $19.50.

BRISTOWE'S TREATISE ON THE PRACTICE OF MEDICINE. In one octavo volume of nearly 1200 pages, with illustrations. Cloth, $5; leather, $6; half Russia, $6.50.

WATSON'S LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. Edited by HENRY HARTSHORNE, M.D. In two large and handsome octavo volumes. Cloth, $9; leather, $11.

FOTHERGILL'S HANDBOOK OF TREATMENT. In one octavo volume of 650 pages. Cloth, $4; half Russia, $5.50.

HARTSHORNE'S ESSENTIALS. In one 12mo. volume of 548 pages, with 100 illustrations. Cloth, $2.63; half bound, $2.88.

FENWICK'S STUDENT'S GUIDE TO MEDICAL DIAGNOSIS. In one 12mo. volume, with 54 illustrations. Cloth, $2.25.

HABERSHON ON THE DISEASES OF THE ABDOMEN. In one octavo volume of over 500 pages, with illustrations. Cloth, $3.50.

HAMILTON ON NERVOUS DISEASES. In one octavo volume of 512 pages, with 53 illustrations. Cloth, $3.50.

BARTHOLOW'S PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATIONS TO MEDICINE. In one very handsome octavo vol. of about 450 pages, with illustrations. (*In press.*)

MORRIS ON SKIN DISEASES. In one 12mo. volume of over 300 pages, with illustrations. Cloth, $1.75.

BUMSTEAD ON VENEREAL DISEASES. In one octavo volume of 835 pages, with 138 illustrations. Cloth, $4.75; leather, $5.75; half Russia, $6.25.

ROBERTS'S PRACTICAL TREATISE ON URINARY AND RENAL DISEASES. In one octavo volume of over 600 pages, with many engravings. Cloth, $4.

CLINICS.

Clinical Lectures.

ON DIPHTHERIA.

A CLINICAL LECTURE DELIVERED AT JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

BY J. SOLIS COHEN, M.D.,

PHYSICIAN TO AND LECTURER ON CLINICAL MEDICINE IN JEFFERSON MEDICAL COLLEGE HOSPITAL, ETC.

GENTLEMEN: It is important that you should acquire as definite ideas as possible of diphtheria; and I therefore invite your attention to that disease, concerning which opinions are by no means uniform, despite the unusual amount of attention bestowed upon it, for the past twenty or twenty-five years, in the lecture-room, in the study, and at the bedside. It is at the bedside, indeed, in my own estimation, that we can alone clearly distinguish diphtheria from croup, with which it is considered identical by the majority of practitioners. The term diphtheria is misleading, derived as it is from διφθερα, *a skin*, *a slough*, and thus applicable to indicate all conditions attended with local manifestations of pseudo-membranes. Croup is a more objectionable term still, as it is applied to a variety of disorders differing in their pathology; but, as it has become too thoroughly incorporated into medical nomenclature to be abandoned, it should be confined to indicate a peculiar sthenic inflammatory affection of the air-passages—the upper air-passages especially—in which the main local manifestation is the development of false membrane upon the mucous surface of the larynx, and in which the main danger to life is the mechanical one due to accumulation of the false product to such an extent as to produce death by actual suffocation, or want of due oxygenation of the blood by prolonged impediment to respiration.

If the term croup be retained as synonymous with diphtheria, which it is not, and be applied to all affections of the air-passages attended with the production of false membrane, then, it appears to me, we are able to distinguish four varieties of croup. Firstly, *true croup*, *sthenic croup*, *idiopathic croup;* purely inflammatory in the usual acceptation of the term, sporadic, non-contagious, and manifested almost exclusively in children. Secondly, *systemic croup*, *the croup of diphtheria*, a condition similar to the first variety, but engrafted upon diphtheria; a specific disease, endemic and even epidemic, though likewise sporadic; contagious; manifested in individuals at every stage of life; and accompanied by peculiar nervous and glandular manifestations which demonstrate its systemic character. Thirdly, *deuteropathic croup*, manifested in some cases of phthisis, syphilis, typhoid fever, and the exanthemata; and, fourthly, *traumatic croup*, due to the local action of boiling water, steam, ammonia, acids, vesicants, corrosive sublimate, mechanical injuries, foreign bodies, and so on.

In all these varieties the false membrane is diphtheritic in the sense of being adventitious; but its presence does not stamp the disease as diphtheria. Diphtheria may exist, indeed, aye, and be fatal too, without any detectable manifestation of false membrane during life or after death. So, therefore, as the idea of true croup is associated with the essential production of false membrane, or its equivalent in a less dense product, we shall be willing to speak of the croup of diphtheria when the presence of the croupous manifestation justifies the expression. Neither microscopically nor chemically can we detect any essential difference between the false membranes of croup and of diphtheria.

Diphtheria, gentlemen, in its typical form, is an adynamic, constitutional, disease, due to specific though not well ascertained causes, and attended with a local pathological manifestation in the form of exudative deposits upon the mucous membranes and upon abraded cutaneous surfaces. It is quite probable that the deposit always commences upon an abraded surface, even on the mucous membrane, because of the catarrhal condition of the nose, throat, and air-passages which precedes the local manifestation.

The mucous membranes especially susceptible to the local deposit are those of the uvula, palate, tonsils, and pharynx. Thence the deposit is liable to extend to the larynx, trachea, and bronchi; to the nasal passages and the interior of the ear; to the various sinuses in communication with the nasal passages; and to the œsophagus and stomach as may be. It is generally believed that certain minute vegetable organisms, emanating from water and air contaminated with refuse, gain direct access to the pharynx and air-passages in eating, drinking, and breathing; and locally poison the system. These organisms are very abundant during diphtheria, but they are quite abundant in every form of sore throat in which morbid products accumulate, and are even present in the healthiest state. Hence it is improbable that they are the sole cause of diphtheria, though diphtheria provides a favourable condition for their development. It is even believed by some pathologists that these minute organisms bore their way mechanically into the organs and bloodvessels and thus poison the system directly, as well as indirectly by decomposition. In the absence of direct demonstration to the contrary, we must be content to believe that the proximate cause of diphtheria has not been detected. The remote cause, or susceptibility of the disease, appears to reside in constitutional debility, or at least impaired vigour, for it is rarely that a robust individual is attacked unless enfeebled by overwork, anxiety, self-indulgence, or something else. Subjects of sore throat are especially liable to contract diphtheria, particularly if their mucous membranes be denuded of epithelium. Hence, perhaps, its liability at times to follow upon the sore throats of the exanthemata. It has long seemed to me impossible to account for the immunity of certain individuals under influences identical with those attending the development of the disease in other inmates of the household, without acknowledging that there must be some special condition of system favourable to the development of diphtheria. A remarkable exemplification of this opinion has recently become historical in the outbreak of diphtheria, less than two years ago, in the family of the Grand Duke of Hesse Darmstadt, the son-in-law of Queen Victoria, in which not a single member of the numerous household retainers were attacked, although several members of the family succumbed. The grand-ducal family, likewise, are now known to have been subject to sore throat.

An incubating period usually intervenes between exposure to the infection of diphtheria and the manifestation of the disease. This period varies, as a rule, from two to five days, but it is by no means definite. Then the throat becomes sore under more or less febrile manifestation, and before many hours a deposit of some kind may be detected at some portion of its surface; and in the great majority of cases in which the air-passages proper are about to become involved, the deposit may be observed on the epiglottis or in the larynx within twenty-four or thirty-six hours. It must be borne in mind that I am describing the usual course of the disease, and that every case you see is likely to differ somewhat from every other case with which you may come in contact. The sore throat will be accompanied by swollen cervical and submaxillary glands, because the sore throat in diphtheria is parenchymatous, deep-seated, involving the submucous connective tissue; consequently the lymph-spaces which begin in the meshes of this tissue become implicated, and convey the irritation to the lymphatic ducts and glands with which the affected portion of the throat is in anatomical connection. One reason why these swollen glands are not observed in true croup, as the rule, is because they are not in anatomical connection with the larynx, and are thus unaffected until the pharynx or tonsils become involved.

The acute febrile phenomena sometimes subside as these local manifestations progress, and sometimes coalesce into fresh ones due to the systemic irritation produced by extension of the local product. This local product appears at first as a lymphous material on some portions of the uvula, palate, tonsils, or pharynx; frequently on one side only, sometimes on both. It is usually coagulated into small whitish or gray specks, more or less translucent and soft at first, but soon becoming opaque and tough. These specks increase into patches of irregular shape and distribution, occasionally amounting to extensive casts upon the surface. These products are the false membranes. They become darker in colour and in consistence; and after remaining *in situ* three, four, five, or more days, gradually exfoliate from periphery to centre, leaving the mucous membrane intact or merely hyperæmic. When forcibly removed, the mucous membrane may be bloody. Their disappearance may be followed and refollowed by successive reproduction of similar products.

Sometimes the false membrane compresses the capillary bloodvessels to such a degree as to obstruct the circulation; and sloughs occur at points nourished by these vessels. This is the gangrenous form of diphtheria, the cadaverous odour of which is sometimes characteristic.

The constitutional disturbance varies greatly, and is often an index to the prognosis. An elevation of temperature of from 4° to 7° F. indicates a probability that the deposit will invade the respiratory tract; and in some instances the extension and persistence of the deposit varies, proportionately, with the temperature. Wakefulness is frequent, and with restlessness at night, often heralds delirium and convulsions in children. The pulse becomes accelerated to 120, 130, or 140 per minute, and usually without the customary proportionate increase in the number of respirations, as is the rule with sthenic diseases. Hence this point sometimes becomes a good bed-side reference in distinguishing true croup from diphtheria. Nor is the pulse apt to be firm and hard, as in simple inflammatory affections; but it is soft, puffy, even, and compressible. The appetite usually fails early in a well-developed case, and this may be succeeded by gastric and intestinal irritation, even amounting to vomiting and diarrhœa. The urine becomes scanty and of high specific gravity, often with various evidences of active renal disease. Albuminuria is frequent, and the quantity of albumen varies from time to time, sometimes amounting to from one to three drachms in the twenty-four hours. The amount of albumen is often indicative of the severity of the attack; and as albuminuria is an infrequent manifestation in true croup, its existence becomes an additional clinical distinction between the two affections when the larynx becomes implicated. Extension of the local lesion to the larynx is indicated by hoarseness, cough, and dyspnœa; the latter in part due to inflammatory swelling, and in part to paralysis of the dilator muscles of the larynx, as well as to the accumulation of the morbid product. Now, too, tumefaction may take place in the lymphatic glands below the hyoid bone, by extension of irritation in the lymphatic vessels in the epiglottis and upper portion of the larynx. The fever increases as the morbid process progresses; respiration becoming more frequent and difficult, and requiring the aid of the auxiliary muscles. Inefficient aëration of the blood becomes indicated by pallor of the face, lips, and nails, and coolness of the extremities; and if the dyspnœa increases, the soft tissues below the sternum, above it, and between the ribs, become deeply depressed at each inspiration, by the pressure of the external atmosphere. The voice and the cough are muffled. All the symptoms just described indicate the approach of asphyxia, unless relief is procured by the spontaneous or artificial discharge of the exudative products.

Symptoms of subsidence of the attack become manifested in favourable cases, at a period varying from the eighth to the fourteenth day, and convalescence commences, accordingly, during the second or third week.

In cases of profound blood-poisoning, the usual adynamic symptoms become superadded; and death from asthenia is apt to ensue in from two to four days after their onset, if the conditions cannot be combated. Ecchymoses, purpura, erythema, and irregular cutaneous eruptions are sometimes manifested in this condition. Should recovery take place, convalescence is rather slow, as a rule.

Recovery is rare in gangrenous cases, and may be followed by irreparable injury from actual losses of tissue and vicious cicatrizations.

It is thus evident that the prognosis is grave in diphtheria. It is impossible to predict safety, even in mild cases; while recovery may occasionally follow the most unpromising manifestations. The vigour of the patient, the character of the epidemic, the hygienic surroundings of the patient, and the efficiency of the nursing attendants, all have their influence. Complications with other diseases are unfavourable. During the first week the danger is from involvement of the larynx, and, this period passed, it then lies in the exhaustion of the system. High temperature, a rapid and feeble pulse, loss of desire to take nourishment, excessive albuminuria, great prostration, irregular eruption, local hemorrhage,—all are symptoms of unfavourable augury.

How, gentlemen, are we to manage our cases of diphtheria? This is the all-important question. We cannot cure it. It has certain stages of evolution through which it must pass, which no specific can arrest; and our duty is to guide the patient through them as safely as may be, and sustain him if we can. Some cases recover spontaneously, there is no doubt, but we can rarely trust to the unaided efforts of the system. The two main indications, in my estimation, are to keep up a supply of nourishment and stimulants, and to provide for the detachment and discharge of the morbid accumulations when they threaten to occlude the air-passages. Depleting measures, formerly recommended in croup, are no longer resorted to in diphtheria;—another clinical point, to my mind, strongly indicative of systemic difference between the two affections. We must bear in mind, as I have indicated, that there is an adynamic blood disease to be resisted, and a local product to be watched. Let us discuss these two points separately. The blood is the liquid flesh, so to speak, in which all recuperative power resides. The healthier the condition in which it can be maintained, the surer the prospect of recovery from the disease. Hence efforts should be made to regulate all contaminating influences that are within our control. We should provide for systematic disinfection of the sick-room in particular, and for disinfection of the whole house likewise. This can be done by the free use of sprays of carbolic acid, or of sulphurous acid. Solutions of sulphate of iron or some other disinfectant should be kept in all the vessels to be brought into the sick-room to receive the discharges, soiled clothing, refuse food, and slops of the patient. In this way we guard against additional contamination of the poisoned blood from the emanations and discharges of the patient himself. At the same time, too, and what is of the utmost importance prophylactically, the attendants of the patient and the remaining inmates of the household are protected in part from direct contagion, and from impairment of reserve vigour, which might render them particularly liable to that contagion.

As to the patient himself, assiduous cleansings of mouth, throat, and nasal passages, should they become fouled from retained secretions, with ample supplies of digestible food, and the administration of a tonic remedy, than which none, perhaps, is more serviceable than tincture of the chloride of iron, will be all that will be required anterior to the appearance of the local morbid product; unless there should be such indication of profound septicæmia or collapse, which would call for large doses of quinia, or alcoholic stimulation, respectively.

And right here, gentlemen, let me direct your attention to a significant clinical fact, the truth of which you can verify by your own studies and observation. It is this: Chlorine compounds, whether administered internally or applied topically, are more frequently efficacious in diphtheria than any other remedies. Read the records of writers and you will see extolled tincture of the chloride of iron, which I place for you in the first rank, chlorate of potassium, chloride of ammonium, chloride of mercury, chlorine mixture, hydrochloric and nitro-hydrochloric acids. Other remedies, similarly extolled, have this in common with the chlorides, that they have disinfectant properties. This adds to the list, sulphurous acid, sulphites and hyposulphites, carbolic acid, benzoate of sodium, and other drugs of similar qualities. But it is not my intention to enumerate the various modes of treatment lauded in diphtheria. The vaunted success in many instances has been due to the misapprehension that prevalence of common membranous sore-throat was prevalence of diphtheria. It will suffice to fix your attention upon those remedies which in my judgment are most entitled to confidence. We return, then, to the tincture of the chloride of iron. It must be administered at frequent intervals and in large doses. The object is to make as profound a beneficial effect on the health of the blood as practicable. Hence, we give from five to twenty or even thirty drops, according to the age and vigour of the patient, *every second hour, hour, or half-hour.* It may be given in glycerin and water, or in diluted syrup of lemon, or in any pleasant way with which you may become acquainted. It is quite probable that the alcohol in this preparation has some beneficial influence, constitutionally: for, as will be stated to you presently, alcohol is of the utmost efficacy once the constitutional vigour begins to manifest rapid or steady deterioration. The frequent deglutition of this remedy, in addition, brings it in frequent contact with morbid products accumulating upon the deglutitious tract; and exerts a desirable physical impression upon those products, akin to that specially sought for, when, as I shall mention shortly, it is resorted to as one of our most trustworthy agents in topical medication.

Chlorate of potassium is extensively administered as a constitutional remedy in diphtheria; frequently in the form of *the chlorine mixture*, which is prepared with an equal number of grains of the chlorate and of drops of hydrochloric acid in plain or aromatic water, infusion of quassia and so on. The dose of the chlorate varies from two to fifteen grains according to the age of the patient, every third or second hour, or more or less frequently as may be. It is quite common to combine this remedy with the tincture of the chloride of iron, and in the same mixture. A better plan is to have the two drugs prepared separately and then combine the mixtures at the bedside, so that the quantity of one drug may be varied if required, without affecting the dose of the other. Let me caution you about an immoderate use of chlorate of potassium. Look out for evidence of renal irritation, and suspend its administration until such untoward symptoms subside. In view of the normal tendency to albuminuria and to renal disintegration in diphtheria, it is important that no abnormal load be laid upon the kidneys whose excretory offices are fully taxed as active participants in the elimination of the poison from the system. The local action of the chlorate of potassium on the mouth and throat, and its excretion through the salivary and pharyngeal mucous glands enhances its efficacy as an internal remedy in diphtheria. It may be given in lozenges or in compressed pills, and allowed to dissolve slowly in the mouth so as to prolong its contact with the diseased surfaces.

Quinia is a remedy much employed in the treatment of diphtheria; in part as a tonic, in part as an apyretic, in part as a neurotic, and in part as an antiseptic. As it is desirable to combine important remedies when practicable, to avoid too frequent dosing, and as chlorine compounds seem to be especially serviceable in diphtheria, in fact in affections of the respiratory organs generally, I prefer the hydrochlorate of quinia to the sulphate. It is fully as efficacious, incomparably more soluble, and can be manufactured at much less expense. It is given in decided doses until there is abundant evidence of constitutional impression. When deglutition is painful or difficult, it may be given by enema; with proper augmentation of the dose. Under similiar circumstances, it is better to persevere in giving the iron and potassium by the mouth, as their topical effect upon the throat is of certain significance.

Alcohol in the form of strong wine, or as brandy or rum, is of the utmost importance when the system begins to give way; and its free administration should not be delayed after the earliest manifestations of decided loss of vigour. At this stage it is of more importance for the time being than any other remedial agent. From half a drachm to an ounce of brandy or its equivalent, proportionate to the age of the patient, may be given at suitable intervals to keep up the effect, be the intervals three or four hours or but fifteen minutes. Indications for its continuance or suspension will be promptly afforded by the general condition of the patient. As long as it is well borne, it may be given to any extent appearing necessary, short of producing actual alcoholic intoxication, especially so when sufficient nourishment cannot be taken. Children readily take a sort of syrup of brandy made by burning it beneath a lump of sugar which becomes melted in the process.

Though other internal remedies are often valuable in diphtheria, especially under varying circumstances, I feel like stopping with the short list just commented on. It is proper, however, to mention a new treatment, highly lauded of late years in Teutonic Europe, but not sufficiently endorsed at present to justify unqualified approval. It consists in the administration of large doses of benzoate of sodium, the use of which is based on the opinion that it arrests the development of the diphtheritic cryptogamia. As considerable attention has been directed to this subject, which has not yet become incorporated into general professional literature, it may be well to mention the formulæ used by Letzerich the promulgator of the method. Five grammes of pure benzoate of sodium are dissolved in forty grammes each of distilled water and peppermint water, to which are added ten grammes of syrup of orange-peel. To infants less than one year of age, two teaspoonfuls of this mixture are given every hour; to older patients the mixture is given in tablespoonful doses, the amount of benzoate of sodium being increased from five to seven or eight grammes for children from one to three years of age; still further increased to from eight to ten grammes for children between three and seven years of age; still further increased to from ten to fifteen grammes for children above seven years of age; and increased to as much as from fifteen to twenty-five grammes for adults. In addition to this internal administration of the drug, the false membranes are dusted over with powdered benzoate of sodium, two or three times a day in mild cases, and every three hours in severe ones. The drug is also administered in gargles; a five per cent. solution being sufficient for older children. I have no experience with this treatment, nor any personal knowledge of it whatever.

I may add, too, a few words as to carbonate of ammonium, sometimes a remedy of great value at moments of sinking. From two to ten grains may be given in syrup of acacia, or other vehicle, to be repeated whenever indicated; and in case of difficulty of swallowing, it may be administered by the bowel in quadruple quantity. In cases of threatening accumulation of fibrin in the right heart, large doses are indicated theoretically on the basis of observations which have shown that its admixture with blood preserves the fluidity of the latter for some time. It is possible, too, that intravenous injections of the solution of ammonia may be resorted to with temporary, if not with permanent benefit at moments of collapse; but I have no data in illustration of the value of the inference.

What shall be done for the sore throat? what for the swollen and painful glands? Pellets of ice placed in the mouth, and renewed more or less continuously, are as grateful and soothing a means of local relief as lies at our command. Iced compresses are used externally by some prominent practitioners; but they cannot always be employed with impunity; and their use should be discontinued if not promptly serviceable. It is often better to apply warm cotton-batting, spongio-piline, or an actual cataplasm. Inunctions with oil, lard, cosmoline, are often useful; care being taken to use nothing which might favour abrasion of the cuticle, lest local infection further complicate the disease. Great pain requires the use of morphia in effective doses by stomach, bowel, or skin, as may be most available. Prompt discharge of the morbid products as they accumulate has been indicated as an important object in the management of our case of diphtheria. How shall this be secured? Shall it be by removing them bodily whenever they are favourably located for detachment and withdrawal? To those who regard the local product and its extension as the more important feature of the disease, such a method seems highly desirable. If there be a circumscribed patch, undergoing spontaneous detachment, there can be no objection to its extraction. Indeed, its removal is indicated, as getting rid of effete material, the decomposing elements of which are being drawn into the lungs at every inspiratory movement; thus adding additional contamination to the blood.

It is quite possible, in favourable cases, to keep the morbid product diffluent by maintaining a warm and equable temperature in the sick-room, which should be well ventilated without exposing the patient to direct currents of air, and providing an excess of humidity of the atmosphere by hanging wet cloths around, or keeping up a moderate evolution of steam near the patient. The moister the products, the more readily they can be expectorated. When they remain dry and adherent, there is no objection, if fully within the reach of instruments, in making an attempt, by a thorough topical medication, to arrest their further progress, and thus remove the local source of danger; but should the first application fail in this object, no repetition should be made. The practice of cauterizing the uninvaded tissue is reprehensible, because the local product is likely to appear on abraded surfaces. Of all the local agents of which I have any bedside experience, the tincture of the chloride of iron has been by far the most efficacious. It should be applied with a swab of cotton or sponge, which is pressed with considerable firmness against the pseudomembrane, so as to favour thorough contact. After the application, attempts should be made by gargle, spray-douche or syringe, to remove the deposit; but forcible removal is not judicious, unless it is already partially detached. Lime-water is the best solution to use in the douche or syringe. So much for the accumulations in the pharynx and nasal passages.

When the larynx becomes invaded, then the best plan I am familiar with is to keep up a constant evolution of steam passing over the face of the patient; and, in addition, to slake a few pieces of lime the size of the fist, by the bedside every hour or two, or whenever the respiration becomes obstructed; covering the vessel with a hood of stiff paper, so as to direct the steam and particles of lime towards the mouth of the patient. I do not subscribe to the opinion that the lime vapour is capable of dissolving the membranes *in situ;* but I believe that the particles of lime inhaled act mechanically, becoming insinuated beneath them at numerous points, and thus affording minute inlets for the watery vapour, which detach them, and facilitate their expectoration by cough.

The use of emetics is indicated in children, to provoke expectoration from the air-passages in the act of vomiting; but the same indication does not occur in adults who are able to expectorate voluntarily. If successful, the emetic may be repeated at intervals of six hours as long as the indications continue or recur. Alum, ipecac, and turpeth mineral are the most reliable agents, and may be tried in the order named; adhering to the alum if it prove efficient. Emesis should not be carried too far, or be repeated if ineffectual, as it exhausts the power of the system without any compensation in the discharge of morbid products.

Should asphyxia be threatened from accumulations in the larynx or trachea, tracheotomy is indicated; and, though most frequently unsuccessful in averting death, it facilitates due access of atmospheric air to the lungs, and often saves lives that would otherwise be lost.

The most careful attention is required after tracheotomy, to keep the artificial passage clear. The stimulating treatment and the lime inhalations should not be discontinued.

The two main indications for favourable prognosis after tracheotomy, are desire for food, and ability to expectorate. All treatment should be subservient to facilitating these great ends.

Paralytic sequelæ sometimes follow diphtheria. They are to be managed on general principles; and they usually subside without leaving permanent traces.

ON MENORRHAGIA.

A Clinical Lecture.

By J. MATTHEWS DUNCAN, M.D.,
Physician-Accoucheur and Lecturer on Midwifery at St. Bartholomew's Hospital.

Gentlemen: It is a matter of course that I shall go over this subject as we have seen it illustrated in "Martha," or as I see it illustrated in my own practice; and I say this, because, if you look into the books, you will see descriptions of menorrhagia as divided into two kinds—active and passive. I know nothing of this distinction. You will find also a distinction drawn according as the discharge is of menses or of blood; but I know nothing of this distinction. I know of menses, and I regard slight losses of blood from the interior of the womb as the same thing as menses in physical characters. Then, again, you will read in books accounts of symptoms. I know of no symptoms except such as are produced by loss of blood; that is to say, I know no special, still less any essential, symptoms of menorrhagia, as distinguished from any other loss of blood.

In all your studies, with a view to practice, I urge upon you the importance of attending to the theory of nomenclature, because a great deal of misleading arises from neglect of this. It is well known to be a common proceeding with inferior practitioners to treat a disease according to its name; but the dangerous influences of nomenclature spread wider than the narrow limit of bad practitioners. The best names given to diseases are, upon the whole, those that have no meaning, that imply nothing but a name; these are the least misleading. A common mode of naming a disease is, as in the example before us, from its chief symptom. Menorrhagia is, for many, a name for all cases where there is too copious a loss of blood at monthly times. But you have here an illustration how much or how little may be conveyed by a name, for a disease which is, in many cases, essentially a menorrhagia, is called hæmatocele; and if you are to have a correct view of this great disease you must keep in mind that in a great number of cases it is a menorrhagia, as you have already learned from cases you have seen in "Martha."

Menorrhagia and metrorrhagia are, in the immense majority of cases, not truly names of diseases, but names of symptoms; and, in such cases, it is very important to keep this in mind, because it is upon this knowledge that your treatment is founded.

A very important part of this lecture I devote to what menorrhagia is not. Many of the things that it is not I shall merely mention; others I shall speak of at greater length.

When you are called to a case, all the diseases I shall name should be made to run through your mind; for, as I have already told you, if you do not think of the diseases, any of which a case may be, you are very unlikely to diagnosticate the case properly; so seldom is a direct mode of diagnosis available.

If a woman has menorrhagia or metrorrhagia, she may have a threatened abortion, or a threatened miscarriage, or a polypus. She may have a uterine fibroid, a uterine cancer, or merely a catarrh of the neck of the womb, or an abraded condition of the neck of the womb which may be confined to that part or spread beyond it. But there are more recondite conditions which you must also keep in mind when you are diagnosing a case in which there is menorrhagia or metrorrhagia.

One of these is endometritis, of which loss of blood is a symptom, sometimes called pseudo-menstruation. A case, probably of this kind, where the discharge lasted fourteen years, a few days ago ran away from "Martha," being forced to do so to look after her husband. That case was probably one of fungous or hemorrhagic endometritis; but the diagnosis was not completed. In many cases, as you have often seen illustrated, perimetritis and parametritis induce pseudo-menstruation, probably by producing congestion, if not inflammation, of the mucous membrane of the cavity of the body of the uterus. This spreading of irritation to neighbouring organs is not confined to the uterus, for you frequently observe it in the case of the bladder. The bladder may be distorted into any shape, squeezed up into any corner, without any vesical symptoms being produced; but in cases of parametritis and perimetritis it is a very common occurrence to have irritable bladder; the irritation being communicated to the slightly displaced and confined organ from the neighbouring inflammation. Ovaritis, of which you have seen many cases in "Martha," is very often accompanied by prolonged menstruation; and in most cases tenderness of the cavity of the body of the uterus indicates that there is a degree of endometritis accompanying the ovaritis. Vaginitis of certain kinds, as I pointed out in a recent lecture, is not a rare cause of loss of blood; and other morbid conditions of the vagina produce what passes as menorrhagia. A rare case of this kind is well worth mentioning. I was called in, not long ago, to a young lady about twenty-five years of age, who was with very great difficulty induced to seek advice for what she herself and her physician regarded as a very insignificant menorrhagia. She was never well. Ordinary remedies having completely failed, she very properly submitted to a vaginal examination, and on the middle of the posterior wall of the vagina there was detected a small growth, soft and about the size of a split tea. It was not tender, but it had a suspicious feeling which I find it impossible to describe. As soon as it was ascertained that it was growing I destroyed it by a strong caustic. At that time there was no disease discoverable but this little tumour; but within three months the patient was dead from a cancer of the whole of the lower part of the pelvis, which began in the way I have mentioned.

A very important source of deception I must now mention and impress upon you, because it is not generally known. Bleeding often takes place from surfaces which are merely tender—which can scarcely be called diseased. These are found around the orifice of the urethra and that of the vagina. In one sense, cases of this kind—and they occur both in young and old—are very trivial; but, if you consider the anxiety of mind and annoyance caused by such loss of blood, you will see that it is important; and, for the success of a practitioner, such cases may be critical. I can best illustrate this by cases. A young sterile married lady consulted me for what she called menorrhagia, which never came on while she was at rest, but only when she walked. She had confined herself to the sofa to restrain it. When she consulted me I could find nothing the matter with her. At my wits' end, I insisted upon her walking and coming to me while the bleeding was going on. It was then, for the first time, that I made quite sure that she did bleed, and I found the bleeding slight in amount, and coming from around the orifice of the urethra. Now, this kind of loss of blood is still more alarming in an old woman, for reasons you well know, and I have in several such cases been able to set a patient's mind at rest by seeing the blood running from tender spots around the urethral or vaginal orifices. This is not new to you, for I have pointed out to you examples in "Martha," in which, when those parts were visually examined, there was a little bleeding from the mucous membrane of the orifice of the vagina. In some this results from walking, in others from no discoverable cause. In all it has been cured by mild astringent lotions to harden the parts. Another source will occur to you in newly married women. The husband will come to you, saying that his wife is menstruating profusely, and you find that this arises from lacerative injury due to sexual connection. Varicose veins in the vulva are not very rare in women who have had large families, and sometimes they occur even in sterile women. They may burst or be opened by injury, and the bleeding from them is sometimes fatal.

Now, all these conditions that I have gone over are very naturally confused with menorrhagia and metrorrhagia until a careful diagnosis is made; and sometimes this careful diagnosis is never made, and the case is mismanaged, or, if well managed, it is a matter of mere good luck, not of intelligent skill.

Before going further I must tell you the distinction of menorrhagia from metrorrhagia; or, rather, I must tell you the want of distinction, for that is as important as the positive side of the matter. A case is one of menorrhagia, and this includes an important class of diseases, when there is nothing to account for the excessive loss of blood, and when there is every reason to presume that the bleeding is menstrual—that is, from the interior of the body of the uterus, at the usual monthly times, and with the usual menstrual symptoms. If you have all these conditions combined, the case is then justly named menorrhagia. When you have absence of indications that the bleeding accompanies ovulation, then you call it metrorrhagia; but the distinction is not really of great importance. In no case is the distinction scientifically sure, but in many it is, for practical purposes, sure enough, and when it is made out it helps you to be an intelligent practitioner in any particular case.

Suppose, then, that you have a case of this kind before you—one that is not to be passed over by writing a prescription and talking to the patient, as very many are—you must then inquire into the following particulars carefully and minutely. First, as to the quantity lost. With regard to this every individual is, to a great extent, a rule for herself. What in one woman would be menorrhagia would in another be classed as amenorrhœa; so great are the variations within the limits of health in different women. Indeed, it would be difficult to say that there is any certain limit as to greatness of quantity except that of influencing the general health. I have seen many cases described as alarming menorrhagia in which it was only necessary to inspect what came away in order to make them appear ridiculous. You must not treat a case for long without seeing the discharge for yourself to judge its amount. A common way of measuring the quantity is by the number of cloths a woman requires during twenty-four hours. Second, the presence of clots and the size of the clots must be inquired into. Third, the time during which the flow goes on is important, for you can easily see that length of time may make a common menstruation of the utmost importance. Within moderate limits, in respect of time every individual is a law to herself. Fourth, you inquire into the quality of the discharge, not only as to the presence of clots, but as to whether it is decayed blood or not, bright red, or chocolate-coloured, or like coffee-grounds. With regard to this brown blood, you must remember that a very small clot will, by gradually dissolving, stain for a long time the mucous discharges from a patient, and may deceive her into thinking that she is continually losing blood, whereas the whole matter, intelligently regarded, may be quite insignificant. Then, fifth, you must inquire into the interval or time of recurrence. And, such is the extreme anxiety—the injudicious over-care of themselves, manifested by many women, and by many mothers—that you will often be consulted about cases called, or held to be, menorrhagia, where the recurrence is only a few hours or a day or two before the time regarded as proper; and I must ask you not to yield yourselves as abettors of any such nonsense, while at the same time you do not fail to be kind and considerate of the feelings of your patients. Such a variation is not a morbid condition, and is not to be treated by drugs. But if the recurrence is greatly in advance of the usual and proper time, then you may have to consider the whole circumstances of the case with a view to its proper management or treatment. Lastly, a most important particular is whether the loss is injuriously affecting the woman's health; it may do this without producing evident anæmia; if it does also produce anæmia, there is no need of further proof that it is producing constitutional mischief.

When you are considering the pathology of a simple menorrhagia or metrorrhagia, what points are you to study? You think of congestion of the uterus or of increase of the blood-pressure; and you may be sure that whatever part is weakest under the influence of blood-pressure will be the first to yield. In most people, especially in youth, the Schneiderian membrane is the weakest part, and yields. In old people this yielding of the Schneiderian membrane, and consequent epistaxis, is often an extremely fortunate occurrence, saving them from the disastrous effects which are sure to follow the occasionally alternative yielding of some atheromatous vessel in the brain. Many cases of menorrhagia and metrorrhagia at all periods of life are no doubt analogous. Congestion of the uterus occurs periodically, as you know, in the menstrual periods of women; it occurs occasionally in the old, and also in the very young. The spurious menstruation of infants almost certainly depends upon a uterine congestion, very like that which occurs in adult women—a curious pathological condition which has its analogue in the congestion, secretion of milk, and sometimes even abscess in the mammæ, of infants.

Then you think of relaxation of the uterus. On examining women who are menstruating, the uterus is found to be bulky, soft, and its os somewhat more open than usual; and this condition may proceed to an exaggerated degree in menorrhagia and metrorrhagia; indeed, in some cases there is, even in the virgin uterus, a dilatation of the whole uterus much beyond its natural dimensions, and the formation of a soft clot in its inside. This dilatation occurs more frequently in women who have had children than in those who have not; but its occurrence, even in virgins, has been verified post mortem, and in such cases the presence of the clot in the uterus, if it is at all long retained, becomes a source of irritation, and leads to persistence of the bleeding.

Next, you must think of the state of the blood; and this important subject I must dismiss in a few words. When a woman is chlorotic she fortunately has generally amenorrhœa; but if not, she will be very liable to have menorrhagia. And you have here an illustration of a vicious pathological circle. The menorrhagia increases the chlorosis, and, *vice versâ*, the chlorosis aggravates the menorrhagia.

Lastly, the condition of the bleeding surface must not be neglected; and it is almost certainly very different in the young from what it is in the old. In the former you have probably a very much healthier tissue-condition than in the latter. In both, no doubt, you have the bleeding surface in a state of partial denudation; and in the old you probably have other senile conditions added to the state of superficial denudation which occurs in all menstruating women. In fatal cases the mucous membrane of the cavity of the body of the uterus has been found sometimes partially separated, and it has also been found to contain small disseminated ecchymoses.

Now for an enumeration of the varieties of true menorrhagia.

In the very young you are liable to have it with the first appearance of the menses. I have seen a young woman, who ever afterwards menstruated naturally, at the point of death from excessive hemorrhage at her first menstruation. In some fatal cases there has been noticed a condition of scorbutus or of hæmophilia.

In the newly married you find a common menorrhagia arising from the recent marriage. The woman supposes herself to be pregnant, passes her usual time a period of weeks or even months, and then has a profuse menorrhagia, which she takes for a miscarriage; and you must be on your guard against the peculiar pride of sterile women, who boast of this as a miscarriage, in order, apparently, to save themselves from what they consider the discredit of absolute sterility. Unless ovuline structures have been seen in the discharges, the evidence of miscarriage is deficient.

In mature, healthy women, menorrhagia is very rare, except as the result of some constitutional affection—the commonest causes being excessive childbearing and suckling, both of which probably act by producing a watery condition of the blood, which flows freely from an ill-contracted uterus. It is at this time of life chiefly that you see illustrations of general constitutional affections producing menorrhagia. Obstructive diseases of the heart, of the lungs, of the liver, as they are liable to lead to other hemorrhages, may naturally be expected to lead to menorrhagia or metrorrhagia. I am bound to say, however, that in practice I have not been able thoroughly to satisfy myself of this influence, except in the case of the liver.

A pregnant woman may have a menorrhagia. This I merely mention. It occurs mostly, if not exclusively, in the first months, and may recur for two or three months. Then, in women recently delivered, but who have passed the six weeks of the puerperal state, menorrhagia occurs not rarely, and sometimes very severely.

In elderly women it is common about the period of the change of life, and it may occur even after the change of life. I have seen some cases in which I could not doubt that sexual excitement was the cause of the loss of blood in women long past fifty-four, which you are told is the limit of childbearing. I dissected not long ago an old lady who had occasional metrorrhagia, and who believed herself to be still sexually young. The body of the uterus was large, like that of a young woman, while the cervix was atrophied; and the ovaries contained structures which were, so far as the naked eye could judge, like large menstrual corpora lutea.

The treatment of this affection is easily described and remembered, because it can all be put under satisfactory theoretical rules. It is not treatment by specifics or remedies which have an unaccountable influence.

Constitutional remedies I shall not mention; everybody understands them. According to the constitutional disease, according to the state of the blood, so do you prescribe your remedies; so, also, whether the disease be in the heart, lungs, or liver.

In all cases where the loss is great you enjoin rest, but only in such. You can easily understand that exercise, stimulating the circulation, will tend to increase the flow. The rest you prescribe must be horizontal; and the patient must not, in extreme cases, get up even for purposes of urination and defecation, for the blood-pressure is greatly and injuriously increased by stooping and pressing down in performing these functions.

Then we come to medicines. Of all with which I am familiar—and I have tried a great number—ergot stands first. In obstetrics you are generally told that ergot produces its effect in about fifteen minutes: that is doubtful even in parturition; but in the unimpregnated woman you must not expect it to act thoroughly till days of its use have elapsed, and in some cases I have observed its use has had no result until it has been continued for weeks without intermission. After ergot, in popular estimation, come gallic and tannic acids. I am not quite sure that they have any effect at all. They may have an effect, and be as rationally used as other medicines. I have used them extensively, and the impression they have left on my mind I have just told you. The medicine which seems to me next best after ergot of rye is sulphuric acid, often combined with some saline; and no injury is done if the saline produce slight relaxation of the bowels. You have not long to wait for sulphuric acid to produce its effect. You may have to give it in large doses, and frequently; for instance you may give one drachm, or even twice as much, in a day, dividing it into frequent doses. The beneficial influence of digitalis and cannabis indica is almost certain, yet in point of reliability these remedies come considerably after ergot and sulphuric acid.

One of the most powerful influences, and one with which I have been long familiar, is the use of heat. Heat is supposed by most people, professional and non-professional, to favour bleeding; but its influence in causing the contraction of involuntary muscles has long been known, and its use in cases of menorrhagia and metrorrhagia, whether simple or not, is very valuable. It is to be applied internally in the form of irrigation, by the passing through the vagina of a large quantity—pints—of water at 100° to 110° Fahr. This is not to be done long at a time, being continued five to ten minutes, and repeated several times a day. It is almost universal to swear by cold as a hæmostatic in our diseases, and I need not say that I have seen it used, and used it myself many times. In the form of ice, applied to the external parts, it is, I think, quite as often injurious as not. It is best used by irrigating the vagina just as is done with hot water, or by placing small bits of ice in the vagina. Even used in this latter way, my impression is that its value is inferior to that of heat.

If all these means fail, you may have to resort to a plug. In the virgin this is very difficult to insert. The operation indeed may be quite impracticable. But if the woman be married, and still more if she has had a child, it is easily made available, and you will often be astonished at the good result of even what seems to be a very imperfect plug. You will sometimes find a small sponge capable of controlling quite a formidable menorrhagia.

I have told you that there are cases of simple menorrhagia even in young virgins that prove fatal; and you are not to suppose that we have nothing to do for them beyond what I have already mentioned. The last remedy is to paint the bleeding surface with "styptic." If the womb is dilated the bleeding surface may be easily reached. If the os uteri be not dilated, you can pass such an instrument as this hollow probe and inject the styptic through it, which will have the same effect as painting. The instrument you see is fitted to a small syringe. Many of you will remember a fatal case of this injection with perchloride of iron, and therefore I hesitate to recommend that drug, although I think it is the most powerful styptic we have. I would advise you to use tincture of iodine; or, if you do use perchloride of iron, it should not be by injection. The bleeding surface may be swabbed with it, so that it may not pass into the veins, which was the disastrous accident in the case referred to. You may also try other drugs, such as a solution of alum.—*Med. Times and Gazette*, Aug. 7, 1880.

Hospital Notes.

Locomotor Ataxy in a Boy.

Harry G., paper boy, aged 13, was admitted to the Sussex County Hospital under the care of Dr. W. AINSLIE HOLLIS, on Nov. 21st, 1879. His mother was alive and healthy. His father had recently died of cardiac dropsy. The patient was the second of six children; five were living; four healthy; one girl died in infancy. There was no history of chorea, epilepsy, or mental disorder amongst his relations.

The patient, an intelligent lad, had had no illness sufficiently severe to keep him in bed, except measles and scarlet fever in childhood. He was stated to have suffered from frequent attacks of diarrhœa, passing blood in his motions. Until nine years of age, he was quite firm upon his legs. About this time, his mother first noticed a weakness in the legs and something "strange" in his appearance, as though he had had "something to drink." There was no personal history of fits, chorea, or of any mental disorder.

On admission, the boy was poorly nourished. He could not stand upright with his heels together and his eyes closed. There was always considerable swaying of the body (static ataxy) when standing unsupported. The head was held stiffly. In walking, the legs were widely separated, and the feet flapped the ground at each step. He frequently fell down, apparently from weakness of the legs, sometimes from giddiness, but he never lost consciousness. Cutaneous sensibility of the legs—tested by pricking, pinching, and the application of warm and cold sponges—was not observably impaired. There was no sensation of walking upon air-balls, etc. Patellar tendon-reflex was absent. (This reflex was only impaired about a fortnight before his admission.) There was some reflex action on tickling the soles of the feet. Muscular sensibility, as tested by the continuous current, was fairly good. The muscles responded to the action of the current, and he perceived their contraction. Muscular power was good. He complained of occasional lancinating pains along the course of the anterior crural nerves. He could not pick anything off the floor without kneeling. The upper limbs appeared to be healthy. He could write a good round hand. He readily touched the tip of his nose with either hand whilst his eyes were closed. The eyesight was normal in strength, as tested by Snellen's types. No amblyopia nor diplopia was observable. The pupils contracted naturally. There was no ataxic movement of the eyeballs upon attempting to follow a moving object with his eyes. At one period of his disease (January, 1880), he suffered for some days from a pain in the left side of his head, followed by a discharge from the left ear. He frequently suffered from giddiness. There was no deafness. He spoke slowly and somewhat indistinctly. His general health was fairly good. There was no loss of control over the sphincters.

During his stay in the hospital, he was treated with iron and strychnia, cod-liver oil, and the continuous current; no perceptible improvement resulted.

REMARKS.—The above case presents several peculiarities worth consideration. First, as regards the age of the patient; among sixty-eight observations, Erb found only three to have commenced between eleven and twenty years of age. The statistics of Carré, Topinard, Cyon, and others, correspond closely with these. Friedreich has certainly noted a peculiar variety of this disorder, which is seemingly hereditary, and begins very early in life. Dr. Bradbury (*British Medical Journal*, 1871, vol. ii. page 499) narrates a case which, in many respects, resembles the foregoing. The patient, however, was eighteen years of age when he came under observation, with well-marked symptoms of ataxy. In this case, an hereditary tendency was probable; so far, it resembles the three cases mentioned by Friedreich, aged respectively fifteen, sixteen, and eighteen (Virchow's *Archiv für Pathol. Anat.*, vols. 26 and 27, 1863). In the *British Medical Journal* (June 4th, 1870), a case of locomotor ataxy, in a man aged twenty-four, is shortly recorded. The disease is stated to have commenced at the age of nine. Dr. Ryott (*Lancet*, August 12th, 1876) also sends notes of a case of this disorder in a patient aged nineteen. The above cases are all that I have been enabled to meet with. Many of them are, from the scantiness of the descriptions, valueless for the purpose of comparison. I think, however, they sufficiently show the rarity of the disease at the age of the boy G., especially if we exclude all hereditary taint.

As regards the origin of the disorder in this case, it will be difficult to ascribe it to any other cause than that of "taking cold." G.'s occupation as a newsboy doubtless gives this conjecture (for want of a better one) an aspect of probability.

Another peculiarity in the case is the rapidity with which the symptoms increased in severity during the last six months. Friedreich lays considerable stress upon the long duration of the disease in the young affected by the hereditary form, lasting as it did in some instances for upwards of thirty years. Kellogg (quoted by Erb) also gives some similar cases of long duration. On the other hand, the absence of severe lancinating pains in the affected limbs (although G. suffered from these pains occasionally, they were by no means a prominent symptom) coincides with Friedreich's observations. In Bradbury's case also the pains were slight.

The co-ordinatory disturbance of speech, the absence of any disturbance of sensibility, or only insignificant ones, are also mentioned by Friedreich as peculiarities in his cases—peculiarities well-marked in the present instance. The rapid development of the ataxic phenomena in the muscles of the eyeballs and the upper extremities, in the latter writer's and in Bradbury's cases, are singularly at variance with the course the disease has taken in the boy G. I think the above case strengthens the hypothesis lately advanced by Tschirjew, namely, that tendon-reflexes (producible in any muscle favourably situated) are due to relations existing between the muscles and the spinal cord. According to this authority, every muscle possesses not only centrifugal motor nerves, but also centripetal nerves, having their origin near the junction of the muscle to its tendon, and passing into the spinal cord through its posterior roots. This nervous arrangement serves the purpose of keeping a constant tension upon the tendons, which tension in its turn reacts as a stimulus to the muscles to preserve their tonicity. When we put into action any group of muscles, the tone of their antagonists commences at once to increase, owing to augmented tension of their tendons. If this muscular nervous system be deranged (as by disease of the spinal cord), the corrective action of the antagonistic muscles becomes lost, and the movements become jerky and uncertain. (*See London Medical Record*, 1880, page 82.)—*British Med. Journal*, July 31, 1880.

MONTHLY ABSTRACT.

Anatomy and Physiology.

Multiplicity of the Spinal Glangia.

The ganglia upon the posterior roots of the spinal nerves are invariably described as single. A subject has been met with by Dr. LEO DAVIDA, of Pesth, in which some of the lumbar ganglia were double instead of single. This observation led him to investigate the condition further, and he has found a similar condition in two other bodies. In some of these the ganglia were treble instead of single. In the first body, that of a man twenty-three years of age, the first, second, third, and fourth lumbar ganglia were double on the left side, but on the right only the third and fourth. In most the ganglia were quite separate, in some they were connected by a gray commissure. The largest was three millimetres in diameter. The posterior root, two millimetres above the ganglion, divided into two, one for each ganglion. There was a difference in the size of the roots corresponding to the size of the ganglia. In the second body, that of a man forty-five years old, on the left side the first four lumbar ganglia were double, and the fifth was treble. On the right side the first two were double and the last three treble; one of the sacral ganglia was also double. In some instances the three ganglia were quite separate, in others they were united by gray commissures. In the third body, that of a man thirty-two years of age, the third, fourth, and fifth lumbar ganglia were double on the left side, the second, third, fourth, and fifth on the right. As these were the only bodies examined, and the condition was found in all, the conclusion was drawn that duplicity of some of these ganglia is the normal condition. The point certainly deserves the attention of anatomists.—*Lancet*, Aug. 14, 1880.

The Formation of Callus.

The mode of formation of callus is a subject of both practical and pathological interest. In the year 1865, M. RANVIER showed that the callus which is formed in simple fractures, in men, and animals alike, passes through a cartilaginous stage, while in compound fractures there is no cartilaginous stage; new bone is at once formed from granulations which come from the medulla of the fractured bone. He showed also that suppurative inflammation does not interfere with the formation of bone in cartilaginous callus, when the latter has once been formed. These researches left still undecided the question of the cause of the difference in the process under the two conditions. This point has been further studied in an investigation described to the Académie des Sciences by two pupils of M. Ranvier, MM. Rigal and Vignal. They find that (1) even in simple fractures the central plug always becomes directly bony in the middle of the medulla, which has assumed an embryonal structure. (2) When a part of the bone is scraped away, either down to the medullary canal or less deeply, the cicatrix is always directly bony, even when union is by the first intention, a fact also observed by M. Ranvier. (3) In a compound fracture, even if the fragments of bone are left exposed to the air for a considerable time, if suppurative inflammation can be avoided, and union by the first intention thus obtained, the callus passes through a cartilaginous stage. (4) That in a compound and suppurating fracture the callus is at first cartilaginous, in the points not invaded by the suppuration, while even in simple fractures, in which the extremities of the bones are, from any cause, bathed in pus, the callus is still primarily bony. These different facts led the investigators to conclude that if in compound fractures the callus is primarily bony, it is because the periosteum, or more exactly the subperiosteal layer of cellular tissue, was destroyed by the suppuration; and they have arrived at the conclusion that this layer alone is concerned in the formation of cartilage, and that the medulla of both the Haversian canals and of the central canal forms bone directly. Several attempts were made to obtain bony tissue from medulla transplanted into the subcutaneous cellular tissue, but all failed, while subperiosteal tissue thus transplanted invariably produced bone which was at first cartilaginous, as M. Ollier had already found. From the lower third of the tibia of a rabbit the periosteum was removed three or four times, so as to destroy all its osteogenic properties. Then, fifteen days after the last removal, the bone was broken in the middle of the denuded portion. Twelve days later, a period at which, in the rabbit, a cartilaginous callus is usually found, the animal was killed, and the examination of the fracture showed that in the midst of granulations proceeding from enlarged Haversian canals, there was a peripheral callus, purely bony. The experiment was repeated several times with the same result. A still more conclusive experiment was the one in which the periosteum was removed from one surface only, and the bone then broken. Upon that surface the osseous callus formed directly, as in the case of compound fractures, while upon the surface on which the peritoneum was preserved the callus was cartilaginous. These experiments show that the subperiosteal layer, when there is active irritation, as in the case of fractures, contributes to reparation by forming cartilage. But there are numerous casés in which the subperiosteal tissue forms bone directly, and experimentally it could be made to form bone or cartilage as well; with slight irritation bone is formed, with greater irritation cartilage. In the same animal the periosteum was exposed on both legs; on one it was irritated gently by rubbing (as with an agate burnisher), and in the other leg it was irritated strongly, and the adjacent soft parts were bruised, so as to cause an extravasation. If union of the wounds by first intention was obtained, in the former osteophytes were found beneath the periosteum on the twelfth day, while in the latter there were only cartilaginous masses. The latter experiment explains the direct formation of bone at the points of the callus which are farthest from the fracture. In the experimental fractures it was invariably found that in the extremities of the oval mass of callus, bone was formed at once—the inflammation at these points being less active, the subperiosteal cellular layer formed bone immediately.—*Lancet*, Aug. 28, 1880.

The Constitution and Relations of Bone Lamellæ, Lacunæ, and Canaliculi, and some effects of Trypsin Digestion on Bone.

This is the title of a study recently made by Mr. De B. Birch, Demonstrator of Physiology in the University of Edinburgh (*Journal of Physiology*, vol. ii., Nos. 5 and 6), of which the following are the conclusions:—

1. A lamella of bone consists of a number of bundles of fibrils arranged in the same plane and in the main parallel to each other, but communicating occasionally by lateral offshoots.

2. Neighbouring lamellæ have the direction of the fibrils set at different angles, and the fibres of alternate lamellæ correspond to each other in direction very closely.

3. There are no elastic fibres in the lamellæ of the Haversian systems.

4. There is a membrane around the lacunæ and canaliculi, isolable throughout

its connections, and especially after treatment with chromic acid and digestion by trypsin.

5. The canaliculi are contiguous with a membrane lining the Haversian canal, this being homogeneous in structure, and of the same nature as the membrane of the lacunæ and canaliculi.

6. These membranes differ in nature from the cementing substance, as evidenced by the above-mentioned reactions, and are not mere condensations of that substance, as their outlines are sharply defined, and perfectly even when isolated by the process mentioned.

7. Periods of cessation in the deposition of Haversian systems of considerable duration probably occur, be the cessation throughout the length of the system or partial, and a membrane is formed at such periods around the temporary lumen similar to that which is afterwards formed round the permanent canal.

8. In consideration of the behaviour of tryptic digestion in producing the appearance described as occurring in the ox's rib, the older intermediate lamellæ are less resistant than the younger ones, and than the Haversian systems and masses of inner lamellæ, some change having taken place in the cement.

Materia Medica and Therapeutics.

Oil of Eucalyptus.

In the *Deutsche Medicinische Wochenschrift*, No. 30, Dr. SIEGEN, of Deutz, narrates some of the results he has obtained from the use of the oil of eucalyptus globulus in antiseptic surgery. He was induced to experiment with it at the suggestion of Professor Binz, and since 1872 has carried on his investigations of its antiseptic properties. He prepares the solution of the oil by dissolving three grammes in fifteen grammes of alcohol, and diluting with 150 grammes of water. In this solution he soaks ordinary gauze. This dressing is applied in the wet state, covered with the usual gutta-percha tissue, and the whole kept in position by means of gauze bandages. Thus prepared, the eucalyptus gauze does not appear to irritate or produce eczema upon even sensitive skin, and is perfectly antiseptic.

In one case of a child with caseous glands of the neck Dr. Siegen operated—first dipping the instrument in a 2 per cent. solution of the oil and washing the surfaces with the same—by scooping out the contents, draining, and applying a wet eucalyptus dressing, as above described. Although the spray was not used in this case, the discharges which had penetrated the gauze were quite sweet upon the third day. The slight amount of pus remained colourless, and on the eighth day the cavities had contracted and healed. In a second case, of a child with right genu valgum, he removed a wedge-shaped portion of the tibia, and, after fracture of the fibula and proper adjustment of the bone, dressed with eucalyptus gauze, using the thymol spray. The bone wound healed forthwith, and on the tenth day after the operation only a superficial strip of granulations remained.

In a child with purulent inflammation of the elbow-joint and fistulous openings, Dr. Siegen performed resection of the joint under the thymol spray, and, after washing out the wound with an 8 per cent. solution of chloride of zinc, dressed with thymol. The discharges from the wound remained, however, still offensive and profuse, whereupon he changed to eucalyptus dressings, having in the first place washed the surfaces with a 1 per cent. solution of permanganate of potash. After the first dressing the secretion of offensive pus ceased, and the wound rapidly healed.

His fourth case reported was an abscess of the knee, which was similarly treated, and with equally favourable results.

Dr. Siegen's experience has taught him that a 5 per cent. solution of oil of eucalyptus may be employed without any drawbacks. Dressings prepared with this solution may be left undisturbed for four or five days, whilst the 2 per cent. solution dressings remain aseptic for three days.

Dr. Siegen's researches confirm those of Schulz, published in the *Centralblatt f. Chirurgie*, 1880, No. 4, on the use of oil of eucalyptus in antiseptic surgery.—*Lancet*, Sept. 4, 1880.

Action of Sugar on Calomel.

From time to time notes have appeared in various journals, warning against the changes said to be produced in calomel by sugar and various other substances with which it is often prescribed; while many therapeutists advise that so long as calomel is being taken, no salted food or acid drink should be allowed. M. VERNE has submitted these views to the test of experiment; he made various mixtures of calomel with common salt (in solution), beet-root and colonial sugar, solution of citric acid, etc.; these he examined at the end of periods varying from 3–15 days. Although at the end of these intervals the mixtures he experimented with showed to the eye slight traces of change, chemically he could find no evidence of the presence of corrosive sublimate, or of any soluble salt of mercury. He refers such accidents as have been reported chiefly to impurities in the drug; as supplied to the chemist, calomel is usually, to some extent, impure, and should always be washed with distilled water and alcohol. The danger of giving acid drinks with calomel is purely theoretical; it was proved that the latter, when exposed for fifteen days to the action of a 20 per cent. solution of citric acid, underwent not the slightest alteration. M. Verne concludes that the subchloride of mercury is a much more stable salt than is generally supposed; it is, in fact, more stable than corrosive sublimate, as solutions of the latter, when exposed to light and the influence of various organic substances, deposit calomel. Non-coagulated albumen, however, at the temperature of the human body, reduced calomel rapidly and easily, transforming it into a slightly soluble albuminate. Neither common salt nor sea salt, at 40° C., had any action on calomel, either when used alone or in the presence of albumen.—*Glasgow Med. Journal*, May, 1880, from *Bull. Gén. de Thérap.*, March 30, 1880.

On Some Important Therapeutic Effects of Chlorate of Potassium.

Dr. ALEXANDER HARKIN states (*Dublin Journal of Medical Science*, May, 1880), that this drug exercises a most potent influence on all maladies dependent on defective nutrition, secretion, excretion, aëration, and molecular metamorphosis—that it possesses the power of developing vital force in weakened constitutions, of retarding the degeneration of the tissues, and of frequently controlling the too rapid advance of senility due to climacteric conditions. He considers the *modus operandi* to be due to the fact of its two elements being oxygen and potassium, which are indispensable to the formation of healthy blood. When a solution of chlorate of potash is taken into the stomach, a portion—as is the rule with iodide and nitrate of potash—is carried off by the kidneys, another portion passes by diffusion into the liquor sanguinis, the textures, the blood globules, and white corpuscles, a third may be supposed to part with these equivalents of oxygen in the blood, leaving behind chloride of potassium, which may be detected in the urine as well as in the blood, of which it is an important element. The dose should be a saturated solution, which is one ounce to twenty ounces of water, the patient taking one ounce of this thrice daily. Its efficacy is increased in chlorotic or hemorrhagic conditions by the addition of tinct. ferri perchloridi. As to the tolerance of the drug, only one well-marked instance was noted where it produced strangury.

As a lotion, Dr. Harkin has found the chlorate of great value, and when using it externally he always gives it internally; in burns and scalds he has found it specially useful, as also in indolent ulcers, in sinuses in the breast in strumous abscesses, etc.

The above paper was read at a meeting of the Ulster Medical Society, and a discussion took place, at which Dr. Withers mentioned a case in which a large indolent sore had healed under chlorate of potash solution, grs. v to the ℥j of water, after everything else had failed. Dr. Browne had found it most efficacious in burns and scalds, and also in mammary sinuses, which were injected according to Dr. Harkin's directions.

Dr. Whitlaw had used the chlorate largely, and did not think that we could get on without it in children's diseases. In tonsillitis and pharyngitis he had found it of service, but he would caution those employing it to stop it after the urgent symptoms had disappeared, as he had found the congestion of the throat kept up by continuing the medicine.—*Glasgow Medical Journal*, Sept. 1880.

Medicine.

The Thermometer in Diagnosis.

Dr. J. B. Bradbury, Physician to Addenbrooke's Hospital, Cambridge, in his recent Address in Medicine before the British Medical Association (*British Med. Journal*, Aug. 14, 1880), made the following interesting remarks on the diagnostic value of general thermometry:—

General thermometry has been found useful in diagnosing cerebral hemorrhage from alcoholic poisoning, the general bodily temperature (rectal) falling at first below the normal in cerebral apoplexy,[1] but not in drunkenness. Such a case is recorded by Mr. Foster in the *Lancet* for December 27, 1879.

General thermometry also assists us in the differential diagnosis of true apoplexy from the so-called apoplectiform seizures, which occur in progressive general paralysis, disseminated sclerosis, cerebral softening, and also from uræmic coma. Charcot says, "I have demonstrated by repeated observations that, in true apoplexy, especially when it depends upon cerebral hemorrhage, the temperature constantly diminishes some moments after the attack, and afterwards remains, generally for at least twenty-four hours, below the normal standard, even when intense and reiterated convulsive fits occur;" whereas, in the congestive attacks (so-called apoplectiform seizures) which occur in progressive general paralysis and in disseminated sclerosis, "the temperature, on the contrary, rises above the physiological standard, and tends to become gradually more and more elevated, during the whole continuance of the attack."

In cases of cerebral softening, according to Bourneville, the "period of initial lowering" of temperature commonly met with in cerebral hemorrhage, is either absent or much less slightly marked; and, after the first two hours in a case of softening, the temperature may suddenly rise to 102° or even 104°, though it soon descends again to the normal standard, and afterwards exhibits altogether irregular oscillations (unless the pons Varolii be the part affected); whereas, in cerebral hemorrhage, it is found that, if the temperature, after the "initial lowering" rises soon after the attack beyond 102.5°, it rarely sinks again to the normal standard, unless under the influence of a shock resulting from fresh hemorrhage (Bastian[1]). "In uræmic coma, according to Bourneville, the temperature of the body begins to fall at the onset of the seizure, and continues to sink as long as the coma persists, so that it may fall as low as 90° Fahr. in fatal cases. On the other hand, in coma due to cerebral hemorrhage or softening, the lowering of the temperature is slighter in amount, and, in cases not fatal within this period, rarely lasts longer than twelve to twenty-four hours" (Bastian).[2]

[1] Charcot on Diseases of the Nervous System, New Sydenham Society, 1877, p. 209; also references there given, especially Bourneville, Etudes Cliniques et Thermométriques sur les Maladies du Système Nerveux. Paris, 1872.

The Nature of the Diphtheritic Membrane.

There have been few subjects in pathology more debated than diphtheria and the special lesion which characterizes it—from which indeed it takes its name; and few about which so much needless confusion and mystery have clung. We may now fairly assume that the vexed question of identity between this disease and that styled "membranous croup" has been set at rest, and it is not intended here to raise it again. At any rate, it has been shown conclusively on all sides that there is no anatomical difference in the two diseases, but only a topographical difference as to the seat of the exudation; and similarly, one by one, all etiological, clinical, and other distinctions have faded before the exhaustive analysis of modern inquiry. Still, however, pathologists have differed much upon the subject of the nature of the false membrane in diphtheria, and it is only one instance out of many in pathological histology which show how various may be the interpretations put upon microscopical appearances. The reason for divergence of opinion is not a simple one. It depends, in one instance, upon the different stages at which the exuded product has been observed; in another, upon the different seat at which it has been formed; and sufficient account has not been taken of such essential points as these, whilst too much stress has been laid upon other and more accidental features. The sad confusion which resulted from the introduction of the terms "croupous" and "diphtheritic," as general pathological phrases, indicative of various forms of inflammation of mucous membrane, with which the German school is to be credited, has done much to complicate the plain facts of the case; and the non-recognition of the fact that the effects of local irritation of a simple kind lead to changes on mucous membranes identical with those produced by the specific irritation of the diphtheritic poison is yet another element which still obscures the subject. A remarkably lucid exposition based upon carefully conducted study of this phrase of the question by M. LELOIR, in the current number of *Archives de Physiologie*, seems to us to be worthy of attention. Although this observer arrives at conclusions differing in some points from those of others, yet he has succeeded well in harmonizing many discordant views, and has placed the matter in so clear a light that we think it well to briefly follow him in the course of his reasoning.

M. Lelior commences by a brief historical summary of the views held upon the nature of the diphtheritic false membrane, and he shows how, from having held the opinion that this is purely a fibrinous exudation, pathologists have come round to view it as one of purely epithelial transformation, the first to enunciate this view being Wagner in 1866. The truth indeed lies between the two schools, and the way at which this has been arrived has been by experiment. Many observers have hitherto tried to establish the identity between the membranous exudations following the application of irritants to mucous membranes and the specific membranous formations, but have been subjected to much hostile criticism, and have failed to carry conviction. Leloir has followed the same course, producing the exudations on the fauces and pharynx in dogs, rabbits, and guinea-pigs, chiefly by means of ammonia, and observing the changes produced both by the naked eye and by microscopical examination at intervals varying from fifteen minutes to two or more days after the exposure to the caustic. He has thus been able to trace all stages of evolution of the false membrane. At first the change is simply denoted by redness of the affected patch, which sets in almost immediately after the application. But already the superficial cells of the stratified epithelium exhibit notable changes. A clear space appears around their nuclei; the cells are enlarged, but remain connected, whilst in the deeper strata there is evidence of their proliferation, and the vessels of the submucosa are gorged with leucocytes. About an hour after the application the patch has assumed a semi-transparent opalescent appearance; the perinuclear clear spaces have enlarged, the cell-protoplasm has become fibrillated and of a glistening character, whilst the nuclei remain in part unchanged, in other parts increased in number but not in character. Thus in this stage the upper layers of what is now a distinct false membrane present a reticulate appearance, wholly due to changes in the epithelial cells themselves; but in a very short time—five to eight hours—this primary reticulum begins to disintegrate, leucocytes and a fibrinous exudation penetrate the meshwork, until there is formed a thick white opaque membrane, that with which we are most familiar in diphtheria. In this third stage of its evolution the membrane can be resolved into two distinct parts—a *superficial*, composed of fibrinous filaments entangling pus-cells, degenerate epithelial cells, and fragments of the primary reticulum, which still persists in a modified form in the *deeper* layer. In the fourth stage the membrane has assumed a yellowish-gray colour, the epithelial reticulum is almost entirely broken up, and replaced by the exuded inflammatory material; and the final stage is that of disintegration of the false membrane, which assumes a pulpy consistency and yellowish colour. If the inflammation has been very intense, the vessels in the submucous tissue are compressed, and necrotic processes of a more or less deep extent take place.

---

[1] Paralysis from Brain Disease, 1875. [2] Ibid.

Now, on comparing these changes with those which take place in pharyngeal diphtheria, a perfect similarity is observed between them. As may be imagined, M. Leloir has had no opportunity of studying the earliest stage of the membrane in this disease, but he was enabled in two cases to meet with areas of exudation in the second or "opalescent" stage, and he found there the reticulum formed from altered cells, the nuclear proliferation, and the commencing invasion of the reticulum by fibrin and leucocytes, just as in his experimental cases; groups of micrococci being found in addition. And so, indeed, with the latter and better known stages of the diphtheritic membranous formation; a close identity was found between it and that produced artificially upon the pharynx, fauces, epiglottis, and vocal cords. In the non-stratified epithelium of the larynx and lower air-passages there is no scope for the formation of the epithelial reticulum, and the false membrane is then almost entirely composed of leucocytes and fibrin, a distinction which sufficiently accounts for the well-known difference in the degree of adhesion to the subjacent mucous membrane in this site as compared with the pharynx. The fact that in diphtheria the membrane will re-form after being detached, whereas it does not in the case of simple irritation, is explained by the persistence of the cause of irritation—the specific poison—in the former case, and its absence in the other; and probably also from the blood-plasma being altered in diphtheria, and able more readily to traverse the coats of the vessels. Thus a diphtheritic false membrane is composed not of material simply exuded from the blood alone, nor of alterations in epithelium alone, but both the blood and the epithelial tissues have an important share in its production, the epithelial elements taking a far larger share in the regions where they are normally stratified than where they exist only as a simple layer; and in the former regions it can be shown how (except in a few rare instances, where the inflammatory exudations seem to pass through the epithelial strata almost *ab initio*) the false membrane is primarily of purely epithelial origin, how it becomes more and more mingled with products of exudation, which finally almost wholly compose it. The suggestion, too, is thrown out that cases of death from asphyxia in children, which may occur in the very early stages of the disease, do so by the glottis becoming occluded by the mere preliminary epithelial swelling in addition to the submucous hyperæmia, before the process has reached the stage of actual membrane formation.

Whilst, moreover, no anatomical basis of distinction exists between diphtheria and croup, neither can any difference be established between the pseudo-membranous products following experimental irritation and those due to the poison of diphtheria. Nay, more than this. M. Leloir declares that the same anatomical identity underlies all membranous inflammations of the mucous membrane, whether this be in "herpetic angina," in "pellicular" tonsillitis, mucous patches, chancres, etc. And, if this be true, we have here only another illustration of like effects following a multiplicity of causes. It is surely far better to interpret facts in this light than to seek in the mere effects of disease for the differences which lie deeper in the organism—viz., the nature and mode of evolution of the so-called "irritant" (in its widest sense) that is at the root of the manifestations. The concluding paragraphs of this paper are taken up with a comparison between these processes and those of pustular eruptions on the skin, but space forbids our entering on the interesting and suggestive inquiries there opened.—*Lancet*, Sept. 4, 1880.

Treatment of Infantile Syphilis.

M. J. Simon, in a course of lectures upon the therapeutics of infancy, delivered at the Hospital for Sick Children in Paris, states that mercury is of real use in infantile syphilis. He advises that the following course of treatment should be rigorously carried on. The child must be rubbed morning and evening with Neapolitan ointment, the friction being made alternately in the axilla, groin, and popliteal space. Four times a day five drops of the Van Swieten's liquor should be administed in a little milk, the dose being increased, if necessary, to thirty or forty drops per diem. A wooden spoon or a porcelain cup should be employed to contain the liquor, since silver soon becomes covered with an amalgam which causes an alteration in the mercurial preparation. This treatment should be continued for some months, the quantity of mercury given being progressively raised and lowered.—*Practitioner*, Aug. 1880, from *Le Progrès Médical*, July 3, 1880.

Hemorrhagic Syphilis.

Dr. J. Edmund Güntz records (*Schmidt's Jahrbücher*) the following interesting case:—

N. N., a female child of a woman who had twice miscarried in the sixth month, and aborted once in the third month. Externally the child seemed healthy and remained so until the fourth day when it became uneasy, and small blisters appeared on its feet. The child did not move its arms at all, and when put into the bath they hung quietly in the water.

When Dr. Deahna, who reports this case in *Wurtemb. Corr.-Bl.* XLIX. 40, 1879, saw the child on the sixth day, the navel-string had fallen off, and the hands and feet were slightly œdematous. On both soles of the feet the corium was exposed, and also on the great toe. On the fingers, on the face near the nose and near the ears, there were blisters with clear water contents; both arms were paralyzed; the feet could be moved; the breathing was free, and the internal organs appeared to be normal. Mercurial baths were prescribed. On the seventh day the blisters near the ear (pemphigus) had coalesced but new blisters appeared on other portions of the body. The first crop of blisters took the form of ulcers. On the eighth day almost all of the blisters had opened, leaving the corium exposed. On the ninth day the doctor observed that blackish crusts formed on the child's lips, and that when they were washed off the tissue beneath was found to be normal; notwithstanding, there was a constant oozing of blood from the surface of the lips and from the mouth. Blood also came from several places where the epidermis was wanting. There were no more blisters formed. On the tenth day large and numerous ecchymoses were observed on the lower portion of the thigh, and two smaller ones on the left conjunctiva; the right knee was swollen, and the child could not sleep, but continually cried out. On the eleventh day there was bleeding from the navel and arms. The bleeding from all the places mentioned continued on the twelfth day, and in addition from the mouth. The child died on the next day.

The author believes that this was beyond doubt a case of hemorrhagic syphilis, as the existence of the syphilitic diathesis in the child was established, and the fact that the parents had had syphilis was beyond dispute. He holds that the claim of Behrend, that the hemorrhagic form of hereditary syphilis follows usually syphilis of a recent date, is not in accord with this case, as the syphilis of the father dated back to 1870 and 1871.—*Physician and Surgeon*, Sept. 1880.

Paralysis in Acute Diseases.

In an important monograph on this class of diseases by M. LANDOUZY,[1] recently published, the author commences by stating his reasons for restricting his subject to the study of akinesiæ or motor paralyses, and amongst them, to *super-added* paralysis (*paralysies surajoutés*), that is to say, those which do not essentially form one with the primitive malady, or which only supervene along its evolution as an epiphenomenon or complication (*Lyon Médical*, July 4, 1880). By so doing, he believes himself to be conforming to tradition, for in the language of the schools, the paralyses in these acute diseases comprise only "those of the paralyses which, supervening, either during the course of or more frequently at the decline of convalescence, sometimes even after the cure of acute diseases, evidently arise from them, are dependent on them, but are only an accessory, purely contingent and even somewhat rare accident." Thus considered, these akinesiæ may be divided into three classes: 1. The paralyses arising from acute diseases; 2. The paralyses which follow acute diseases; 3. The paralyses evoked by acute diseases. These paralyses have been pointed out under a great number of different conditions. The writers of the eighteenth century have noted them in variola; J. Frank, after dysentery; Delius of Erlangen, in scarlatina; Baillarger, after erysipelas, etc.; but it is especially diphtheria which has furnished the greatest number. To this disease are referable the antiquated facts of Bellini (1680), of the elder Chomel, of Ghesi, Samuel Bard, etc.; to it also are owing the recent researches of Orillard, Trousseau, Lasègue, Maingault,

---

[1] Des Paralyses dans les Maladies aigues. Par Dr. L. Landouzy. Paris: Baillière et Cie.

Gubler, etc. All these paralyses, however, do not behave in a similar manner; according to the disease in which they originate, they show themselves under different conditions of form, duration and evolution. On this point, that opinion of Gubler's cannot be accepted, which, according to his happy expression, believes in the equality of acute diseases in presence of the paralyses. On the contrary, each one of them requires a separate description, and this chapter of clinical analysis forms the first part of M. Landouzy's book. In the first rank we find the diphtheritic paralyses, of which the frequency is great: 26 out of 210 cases, according to Rayer, and 10 per cent. according to Sanné; therefore they have more specially attracted attention. Sometimes generalized and sometimes local, they may attack many regions; as a rule, it is the muscles of the velum palati and of the lower limbs which are attacked by inertia (81 times out of 117), but the motor troubles sometimes localize themselves on the bladder and rectum, the motor muscles of the eyeball (Perati), the agents of accommodation (Trousseau), or even, though more rarely, on the diaphragm and the muscles of the face (Rosenthal). The longer the time from the commencement of the diphtheritic attack that elapses before the appearance of these paralyses, the more they have a tendency to generalize themselves rapidly. There is no relation between their gravity and the apparent degree of the primary intoxication, any more than with the presence of albumen in the urine, a fact to which a certain importance had been attached up to the present time.

M. Landouzy very rightly lays stress on the diaphragmatic paralyses of diphtheritic origin; they are greatly to be dreaded when, in children, after a pultaceous angina, fits of cough and dyspnœa supervene suddenly. Cardiac paralyses, with the paralyses of the œsophagus, are also to be feared, since they represent the most frequent *modus operandi* of death in diphtheritic paralysis. This is an important point, and one well calculated to disturb the calm of those who are inclined to believe in the almost total immunity from diphtheritic paralysis. The bulbar localizations of diphtheria are less rare than is supposed, and such attacks are often the most sudden. M. Landouzy relates, under this head, two cases which came under his own personal observation, of death by syncope, precisely at the moment when danger appeared to be least imminent.

After diphtheritic paralysis, those most frequently met with are unquestionably typhoid paralyses. Like the preceding, they show themselves under the most varied aspects, paraplegia, hemiplegia (Nothnagel), sensorial paralyses, vesical paralyses (Béhier and Hardy), bulbar paralysis (Bailly, Marotte, and Liouville), according as they may be slowly or suddenly generalized, or finally localized. The cases of paralysis of the posterior crico-arytenoid nerves collected by M. Villemin and others, after even slight attacks of relapsing typhus, may be relegated to this category.

Typhoid fever may also give rise to certain motor troubles of a peculiar aspect, such as certain tremblings pointed out by some writers, of which some may put on the appearance of a true sclerosis in patches. The case reported by A. Chauffard affords an interesting example of this class. In this category of facts may also be placed aphasia following enteric fever, a complication which is now thoroughly recognized, and of which Trousseau and J. F. Weisse have cited the first cases. Thus, adds M. Landouzy, paralysis in typhoid fever seems to influence either the centres or the nerve conductor, or the muscle itself.

After the typhoid paralysis comes the turn of paralyses in petechial fever and acute dysentery, with the examination of the doctrine of reflex paralyses in cholera and intermittent fever.

The study of paralysis in connection with variola is of serious interest. The examinations after death, which have been made during later years, contribute to a great extent to clear up the pathogenesis of these various disturbances. They are not so frequent as was originally supposed, since, out of a total of 2000 patients, M. Huchard has scarcely found ten cases of paraplegia; but the cases are complete, thoroughly observed, and accompanied by incontestible anatomical verifications. Amongst the latter, the most interesting points are those of atrophy localized in consequence of parenchymatous neuritis pointed out by Joffroy, and the cases of progressive paralysis, with diffused myelitis, which may be credited to Westphal.

As to the paralysis in connection with pneumonia already thoroughly studied by Graves, Macario, Rosenthal, Charcot, and Vulpian, and finally and especially by Lépine, their principal interest consists chiefly in the history of the theories to which they have given rise. Considered by Gubler as of anæmic origin, to Lépine they are only the result of atheroma of the cerebral vessels. The hemiplegia of pneumonia, in fact, is almost exclusively met with in old people. As to the pleuritic hemiplegia on which theses have been written by Valicourt, Bertindu, Chateau, Aubuin, etc., the principal characteristic is the absence of intellectual disturbance, impediments of the speech, and the presence of a certain degree of variation. It is especially after purulent pleurisies and washings out of the pleura that the opportunity of observing them has been met with.

In order to form an exact notion of the direct conditions of the mechanism and of the nature of paralysis in acute disorders, in fact, to comprehend in what relations of subordination they stand in connection with each other, two principal questions ought previously to be answered. 1. Is the element of pyrexia capable of hindering the action of the neuro-muscular system? 2. What are the exact data furnished on this question by *post-mortem* examinations?

To the first question, M. Landouzy answers unhesitatingly in the affirmative. Pyrexia may act on the neuro-muscular system in two ways, either by bringing on hyperthermic lesions in it, or by impregnating the nerve-axis with morbific agents, like the toxic myelites, of which the existence is now thoroughly acknowledged. Hyperthermia acts on the muscle from the absence of oxygenation, which brings on the local death of the contractile elements (thick disks), or, indeed, by production of colloid degeneration, or the mouldy condition (*etat moisi*). It affects the nerve-conductor (a much more uncommon fact), and may then bring on a true parenchymatous neuritis, a process of which Joffroy's cases are full of remarkable examples; finally, it affects the nerve-centres, as Buhl's observations and Renaut's most recent researches on the hortensia tint seem to prove. The colouring matter of the blood, escaped from the globular element dissolved by heat, filters with the sanguineous serum which serves it as a vehicle across the connective meshes of the gray cerebro-spinal masses; the nerve-element no longer finds in this pathological medium the essential elements of its regular nutrition, and its existence is thus compromised.

As to the impregnation of the nerve-axis by the morbific agents, does it not obviously appear, in presence of the almost constant spinal fashion of the majority of these paralyses, of the intense rachialgia of variola, of the cervico-dorsal pains of typhoid fever; finally of the meningeal inflammation, of which several necropsies have revealed the existence? In fact, the *post-mortem* examinations now performed with a delicacy which the observers who lived at the beginning of the century had no prescience, have proved the existence of these material lesions in the most distinct way; whether variola, typhoid fever, or diphtheria be taken, it is seldom that anatomical disorders, corresponding exactly with the extent and degree of the paralytic disturbances observed during life (diffused myelitis in smallpox, according to Westphal) meningitic patches, degeneration of the anterior roots in diphtheria as discovered by Oertel, Pierret, and Déjérine, are not to be met with.

At the present time, therefore, we find ourselves far in advance of the theoretical ideas which had led the first observers to describe these paralyses under the name of asthenic paralysis of convalescence, of diffuse essential reflex paralyses, etc. Can the peripheric origin itself yet be retained, in presence of this quasi-general consensus of the description of central lesions, especially since the important researches of M. Ranvier, who has demonstrated that the first result of a ganglionic central lesion was to provoke an immediate alteration in the peripheric extremity of the corresponding nerve-conductor (of Doyère's patch)? However, whilst seeming thus to have as a common link the same point of departure, all these paralyses do not reveal an univocal process. They also differ in their local determinations. These differences have their *raison d'être* in individual predisposition, but especially in the nature of the injuring cause. It is easy, in fact, to comprehend that variola and diphtheria do not proceed in the same way in their work of destruction; the first acting specially by the hyperthermic method, like dothinenteritis, the second seeming to strike the nerve element especially by means of toxic impregnation.

M. Landouzy gives some interesting particulars of the theory of ascending neuritis (the neuritis migrans of the Germans), a theory especially supported by Friedreich and Leyden, who consider the spinal lesions as consecutive on the propagated inflammation of the palatine nerves. This theory, which the facts of paralyses of the velum palati supervening in the course of a cutaneous diphtheria seem already to have made doubtful, does not seem to have been sufficiently demonstrated, notwithstanding the experiments of Tiesler and Finberg.—*London Med. Record*, Aug. 15, 1880.

Hysterical Anæsthesia.

At the late meeting of the British Medical Association, Dr. Bristowe made the following remarks in introducing a discussion on hysterical anæsthesia:—

It resembled, he said, other forms of hysteria in its actual characters. There was, for example, anæsthesia as regards touch, temperature, pain, and the condition of the muscles. These conditions were often associated; but cases now and then occurred in which analgesia was more marked than the other phenomena. In a still larger number of cases, the conditions were more or less modified. In regard to the sense of heat and cold and touch, anæsthesia depended a good deal upon the extent of surface touched. He had observed in some cases, where there was total anæsthesia to ordinary touch and to pain, as shown by pricking the skin, that the patient had felt when he had grasped the limb. In many cases, anæsthesia on one side was connected with hyperæsthesia on the other side, or in some other region; and even in the surface which was anæsthetic, certain portions sometimes remained hyperæsthetic. The muscular condition was often altered. There was some loss of power, some rigidity, some loss of the muscular sense, in virtue of which the patient was unable to use the hand or determine the position which it occupied. With regard to inco-ordination of movement, he had failed to recognize it. In a large number of cases, anæsthesia was hemiplegic, and in some few cases it was general; it perhaps affected the whole body, or one part at one time and another at another; and sometimes it was transferred from one side to the other. In one of his cases, three-fourths of the body were anæsthetic, the other portion being hyperæsthetic. In other cases, the anæsthesia was irregularly distributed. In many cases, the organ of special sense suffered in a remarkable way: hearing was impaired; the taste was modified; the sense of smell disappeared in a greater or less degree; and the sight became affected. In ordinary hysterical anæsthesia, the taste was not always impaired; sometimes it was totally annulled on the affected side, and some patients had no taste at all. The sense of smell was often absolutely abolished on the affected side. The patient was generally incapable of distinguishing colours. Red was most frequently recognized, or its recognition was the last to disappear; and sometimes everything was described as looking white.

The first case to which he would call attention was that of a widow aged 31, who came under his care in hospital in July, 1879. She had been shipwrecked on one or two occasions, and on the last occasion (three years ago) had lost her husband. She had suffered from hysterical fits, and had anæsthesia. On coming into the hospital, the fits had almost entirely disappeared; but there were anæsthesia on the left side of the body, pain in the region of the ovaries, loss of taste and smell on the left side; and sight and hearing were totally unimpaired.

Another case was that of a girl aged 21, admitted in July last. She was first attacked with stiffness and pain in the neck, and sore-throat, in June. The muscles on both sides were affected; the thyroid body was enlarged and tender on both sides; there was tenderness of the left ovary, and total anæsthesia of the left side. She did not recognize heat and cold distinctly; she had a total abolition of the sense of pain, and almost of the sense of touch; she had lost taste on the left side, and smell in the left nostril; there was impairment of hearing in the left ear; the recognition of colours with the left eye was impaired; she called red, red, blue green, green blue, and yellow white. Those peculiarities were constant, and the patient was still in the hospital.

The third case (admitted in July, and still in the hospital) was that of a girl aged 18. The affection came on two years ago with fainting fits and pain in the spine and in the left hip and knee, and failure of sight for three months. She had anæsthesia to the middle line. There was tenderness of the left ovary. She could not distinguish between heat and cold; there was loss of taste and smell, and partial loss of hearing; recognition of colours, except red, bright green, and blue, was impaired. She had partial hemianæsthesia and an impaired muscular sense.

The next case was one of hysterico-epilepsy that had been under his care more than twelve months. The patient, a girl aged 18, had epileptic attacks, followed by anæsthesia on the left side of the body, subsequently passing over to the right side, and involving the whole of the body. She was paraplegic, and had hysterical asthenia. She was now probably in one of the London workhouses or infirmaries.

Another case was one recently published by Dr. Stone; that of a girl fifteen years of age, who had come into hospital attacked with hystero-epilepsy at the time of her first menstruation. It had been brought on remotely by an accident in which she had struck her head, but more immediately by reading some horrible story. Her attacks could be stopped by pressure upon both ovaries. She had hyperæsthesia of the lower extremities, and anæsthesia of the body above the navel. In the course of time, the anæsthesia extended so as to involve all parts of the body except the right lower extremity, which was hyperæsthetic. Not long ago, she had been sent from the hospital perfectly cured.

Another case, also under the care of Dr. Stone, was that of a girl who had complained of pain, supposed to be rheumatic, in the muscles of the arm and leg and other parts of the body for two or three months. She had attacks of laughing and crying. On admission, it was found that she had lost the sight of the left eye; everything looked like a fog; she did not recognize colours or forms. After a short time, sensation returned, and she recognized everything; but, either immediately after or a little before she recovered her sight, she became temporarily anæsthetic on one side, lasting for a few hours—tending to show that the case was one of hysterico-anæsthesia; and that the impairment of sight, which, taken apart, might have been misunderstood, was also an anæsthetic phenomenon.

He would next draw attention to the distinction between hysterico-anæsthesia and the other forms. With regard to hemiplegic anæsthesia, he confessed that he did not recognize any clear distinction between that and hysterical anæsthesia. It was attended with loss of sensibility to pain, impairment of the recognition of heat and cold, and all the various phenomena characterizing hysterical anæsthesia. The patient not unfrequently lost the sense of taste on the same side as the anæsthesia, and not unfrequently lost the sight of the eye on the corresponding side. Within two or three years, he had three well-marked examples of that. In one case, a man aged between thirty and forty was attacked with an apoplectic fit; and, when he came to himself, he was found to be not only completely paralyzed on the left side, but completely anæsthetic on that side. There was deviation of the eyes, head, and neck, towards the affected side of the brain; and he was absolutely blind in the left eye for two or three days. The ophthalmoscope revealed nothing wrong in the posterior part of the eye. The patient recovered.

In the cases he had mentioned, the sense of smell was impaired on the left side. It was difficult, however, to determine such points in cases of apoplexy, because the patient was often affected in his mind, and not able to explain his condition. Three cases showed blindness. In one, it was temporary, involving both eyes; but the patient recovered. A case of cross paralysis had recently come under the care of Dr. Barlow. It was that of a man thirty-nine years of age, who was attacked with giddiness, vomiting, drawing of the mouth to the right side, and inability to swallow. On admission, he was found to have paralysis of the left portio dura nerve, partial paralysis of the external rectus of the eye, complete anæsthesia of the upper part of the body down to the waist. The smell was imperfect: hearing on the left side was weak. The eyesight was not carefully investigated. The patient recovered in two or three days. The point of interest was, that anæsthesia affected one side of the body, without any loss of power. The patient could use his hand perfectly. He presumed the case was due to some effusion of blood, or to some affection of the medulla oblongata.

Anæsthesia was very likely to occur after diphtheria, and he had recently had several such cases. One was that of a clergyman aged 33 or 34, who came into the hospital after an attack of diphtheria which occurred two months previously. He presented most of the characteristic conditions of diphtheritic paralysis. There were defective accommodation, owing to paralysis of the muscles of the eye; difficulty of speaking and swallowing, owing to paralysis of the abductors of the larynx; loss of power in both hands, both forearms, both lower extremities; also anæsthesia, which was considerably distributed, in the hands, the forearms, the legs, the tips of the nose, the lips, the tip of the tongue, the chin, the penis, scrotum, and rectum; the evacuations passing without his knowledge.

The distinctions between hysterical anæsthesia and the other forms were not so much in the anæsthesia itself as in the collateral circumstances associated with it. There were but few cases of hemiplegia with organic disease and anæsthesia which one would confound with hysteria; but they occasionally occurred. And there were very few cases of paraplegia of organic origin which would be confounded with hysterical anæsthesia; but he could produce examples; and so with regard to other forms.

The members present were acquainted with the investigations of M. Charcot as to the application of various metals, magnets, and other agencies, producing a restoration of sensation on the affected side, and a transference of the anæsthesia to the other. In most of the cases he had narrated, experiments had been made as to the effect of the application of metals, but not with sufficient care. In the case of the woman whose husband was drowned, gold was applied to the cheek on the anæsthetic side, and in half an hour sensibility was restored, and the opposite side became anæsthetic. He had tried the effect subsequently with other metals, but without success. In the second case, that of the girl aged 21, it was found that copper, zinc, and the magnet had a slight effect upon the skin, producing, after twelve or twenty-four hours, a temporary return of sensation, but no transference of the anæsthesia on the other side. In the next case, copper, iron, and the magnet had slightly the same effect. In case No. 2, no applications over the eye had any effect in restoring sight. Case No. 4 showed no particular effects. In Dr. Stone's case, the application of gold caused a transference of the hyperæsthesia to the anæsthetic side, and the magnet caused a return of sensation to one leg.

Dr. MATTHEWS DUNCAN (London) said that, in the inquiries under discussion, he recognized progress in the way of observation; much had been done in arranging the diseases and finding connected groups of symptoms and phenomena. But besides this, which was a great matter itself, he knew of no decided advance in this limited department of pathology. He thought there was a greatly prevalent omission of the study of the artificial forms of these diseases. In the days of mesmerism and electro-biology people saw, in any evening party, these diseases produced experimentally, or for amusement—anæsthesia, contracture, catalepsy—splendid examples, quite as perfect as the clinical cases now related. Indeed, one could not listen to or read such cases without seeing plain and admitted evidence of their being not altogether spontaneous, but to a great extent artificial. In saying they were artificial, he implied that the artifice was partly by the patient and partly by the practitioner, and he would carefully guard against being supposed to imply anything like collusion or bad faith. Of the good faith of all concerned, he had no doubt. But his remarks would be directed chiefly to the great part played by the ovary in these affections; for with the state of this subject he was intensely dissatisfied; he noticed a want of scientific precision or positive error in the best writings. He would refer to Charcot, for whose great works he had the highest respect. He (Dr. Duncan) had lately seen three characteristic examples of these hysterical diseases, one, a case of left hemianæsthesia with contracture, one of hystero-epilepsy, and another of the same with cataleptic attacks; and in none of these did he find any of the so-called ovarian symptoms or pressure-phenomena.

Charcot gave directions for finding in the abdomen the seat of this ovary; and, speaking of palpation in the region of the ilio-pectineal line, he said that towards the middle of this rigid crest the hand would usually meet with an ovoid body, elongated transversely, which when pressed against the bony wall slipped under the finger. This was an error. The ovary was not to be felt in this way. But this was not all, for such so-called feeling was reduced to an absurdity when it was described as being done, or the ovary was described as being pressed to stop an epileptic fit, when there was tetanic rigidity, the belly being prominent, greatly distended, and very resisting. There was only one way of feeling the ovary; namely, by bimanual examination, the finger in the vagina or rectum touching or pressing on it. He had been feeling ovaries in this real and undoubted way for thirty years and more, and he had never seen any of the wonderful phenomena produced, which were said to be the result of the imaginary pressure which Charcot described. By this imaginary internal pressure it was said that, in certain cases, there were produced intense sibilant sounds in the left ear, which the patients compared to the strident noise produced by the whistle of a railway engine, a sensation as of blows from a hammer falling on the left temporal region, and a marked obnubilation of sight in the left eye. This marvellous set of productions he had no hesitation in characterizing as artificial, or, rather, purely imaginary, as, indeed, a mass of bad observation. The same author taught his students that very commonly the use of the catheter in hysterical cases might need to be continued for months, nay years; and this was teaching a great and grave error. There was no such need. Were any confirmation required of the tenor of his remarks, he (Dr. Duncan) might find it in the suggestion in the same lectures that a hysterical woman might live long without passing urine, or only two or three grains of urea daily, and that she might get fat, or at least keep up her alimentation, by a quite inadequate supply of food.—*British Med. Journal*, Aug. 28, 1880.

Case of Cystosarcoma of the Brain.

At the meeting of the German Surgical Congress in April, Dr. SONNENBURG, of Strasburg, showed a cystosarcoma of the brain, removed from a girl aged 13, who had been a patient of Dr. Lücke. She was said to have had inflammation of the brain in her first year, since which she had had a gradually growing tumour on the left anterior half of the skull. If this tumour were pressed, giddiness set in; she had had epileptic attacks for three or four years. There was no defect of intelligence. Pulsation was distinct. An accurate diagnosis could not be made during life. By puncture a clear indifferent liquid was evacuated; and the canula came into contact everywhere with smooth walls. The treatment consisted in drainage by a silver wire and counter-opening. The profuse secretion prevented antiseptic treatment from being carried out. Death occurred in eight weeks from meningitis. The necropsy presented a number of cranial defects, into which the dura mater covering the tumour protruded. The tumour itself proved to be a gliosarcoma of the large left frontal lobe, extending to the neighbourhood of the lateral ventricle, which was dilated; it was softened in the centre. After the application of the drainage, the epileptic attacks ceased.—*London Medical Record*, August 15, 1880.

Unilateral Convulsions due to Brain-Disease.

An analysis of more than 500 cases has led Dr. BROWN-SÉQUARD to the following conclusions as regards unilateral convulsions due to brain-disease. 1. These convulsions can be caused by a lesion in almost any part of the brain. 2. They can be produced by any kind of lesion. 3. They can be associated with any other symptom of brain-disease, or may be, for a time or till death, the only symptom existing. 4. They can appear at once in all parts of one side of the body, or begin in any muscle or group of muscles (eye, face, neck, trunk, or limbs). 5. They can pass into general convulsions or follow such convulsions. 6. They usually last longer than general convulsions due also to brain-disease, and still longer than genuine idiopathic epileptic convulsions. 7. They often appear without loss of consciousness, either at their beginning or at any time of an attack. 8. They can take place either on the side of the brain-lesion which causes them, or on the opposite side, the cross convulsions being more frequent than the direct ones. 9. The right limbs are attacked more frequently than the left, in cases of direct or of cross convulsions, and also when unilateral convulsions appear in cases of lesion in the two cerebral or cerebellar hemispheres. 10. In the same individual and from a single lesion, unilateral convulsions can appear at first on the side of the lesion and then on the opposite side, or *vice versâ*. 11. These convulsions can appear on the side of hemiplegia or on the opposite side, the paralysis in either case, being a cross one; but they can also be direct when the paralysis is also direct and cross while the paralysis is direct. 12. Direct unilateral convulsions are more frequently produced than cross ones by lesion of the great cerebral ganglia, the crura cerebri, the cerebellum, the pons Varolii, the medulla oblongata; while, on the contrary, cross convulsions are much more frequently than direct ones caused by lesions of the centrum ovale or the convolutions. 13. In animals, as he had found, an irritation of the base of the brain and even of the motor part of the crura, the pons, and the medulla (the anterior pyramid) generally produces muscular contractions on the corresponding side; while irritation of the so-called motor centres, or of the fibres uniting these parts with the cerebral ganglia, usually produces movements on the opposite side, so that the same general effects are generated in animals as in man. 14. Jacksonian convulsions (either when exclusively and persistently unilateral or only temporarily so) can appear on the side of the lesion, or from lesion in parts of the brain considered as not belonging to the motor apparatus. 15. The study of unilateral convulsions brings forth a large number of facts altogether in opposition to the views now held about cerebral localization. 16. The diagnostic significance of unilateral convulsions is often considerable, owing to the association of this symptom with other cerebral morbid manifestations.—*British Med. Journ.*, Aug. 28, 1880.

On Paralytic Chorea.

At the recent meeting of the British Medical Association, Dr. W. R. GOWERS read a paper, the object of which was to direct attention to a variety of chorea which sometimes presented a difficulty in diagnosis. Three symptoms might ordinarily be recognized in chorea: spontaneous movement, inco-ordination of voluntary movement, and muscular weakness. These were not always proportioned. Any one of them might so predominate as to give a special character to the case. In the form now considered, the last-named element (muscular weakness) predominated, and appeared, at first sight, to be the only symptom. A series of illustrative cases were narrated. The arm was always the part affected, and the muscular weakness, which alone was noticed by the friends, and sometimes by the medical attendant, might be very great and real. In some cases, however, the natural weakness might be less than the loss of use would suggest. There was no weakness of face, tongue, or leg. Close observation would, after a time, usually detect a slight occasional choreiform twitch, but this might be quite absent. There might be marked twitching in the other arm, which was not weak. The affection might pass off without more conspicuous spasm. Sometimes choreiform movements become more marked as power increased. The course of this form was often tedious, but did not pass into severe general chorea. The variety was brought under the notice of the Section chiefly on account of the diagnosis; since, in several cases which had come under the author's notice, the nature of the affection had been misconceived. In his experience, whenever a child, between the ages of seven and fifteen, presented gradual loss of power in one arm, without affection of the face, tongue, or leg, the disease was always chorea. Even although choreiform movements might not be observed, the subsequent progress of the case would always justify the diagnosis. The paper concluded with some remarks on the possible relation of the change in the nerve-elements in this form to that which underlay ordinary chorea.—*British Med. Journ.*, Aug. 28, 1880.

Symptoms in Menière's Disease.

J. GOTTSTEIN (*Zeitschrift für Ohrenheilkunde*, Band ix.) arranges the forms of disease connected with deafness and disturbances of equilibrium (Menière's disease) in two groups: 1. Those in which the affected persons, mostly children, present symptoms which may be called meningeal irritation, are ill for a shorter or longer time, and after complete recovery retain the deafness and the staggering walk; 2. Those in which deafness and giddiness suddenly appear without disturbance of the general health. The cases of the first group are referred by the author to cerebro-spinal meningitis, contrary to the view of Voltolini, who includes them under the name of "otitis labyrinthica." This view is supported by the circumstance that, among 254 patients with ear disease, who came under treatment from March to October, 1879, twenty-five cases were found with the so-called otitis labyrinthica. It almost seemed as if there were an epidemic of this affection. Six cases must be excepted, the beginning of which dated a year and more back. Among the remaining nineteen cases there were again six, in which, partly with certainty and partly with more or less probability, meningitis was found to be the starting point of the symptoms of Menière's disease. In the remaining thirteen cases, there was fever with violent headache, and in two cases only was vomiting absent at the beginning of the disease; in nine of them there was more or less profound benumbing of the sensorium; in three cases only, fever, headache, and vomiting, were the sole symptoms which preceded the ear-disease. All the patients, except one, belonged to the classes who live on poor food, and their ages varied from two to sixteen years. With regard to this phenomenon, and to the circumstance that an epidemic of cerebro-spinal meningitis prevailed (in Silesia) at the time when the author observed these cases, Gottstein does not hesitate to connect them with this epidemic. Of what nature the morbid process is which affects the organ of hearing in this malady, he has not been able to determine, in consequence of absence of anatomical and pathological researches. Of cases of the second group, which, on account of the suddenness of the onset, Gottstein designates an apoplectic form of Menière's disease, the author has seen three only. In all these, the affection was of a secondary nature. In the first case, the primary malady was tabes dorsalis; in the other two, leukæmia. The author desires by his contribution to give a stimulus to the decision of the question, whether the genuine disease of the acoustic nerve in its course and in its termination occurs really so frequently as it has been hitherto assumed.—*London Med. Record*, Aug. 15, 1880.

Primary Carcinomatous Hæmorrhagic Pleuritis.

Dr. Savard (*Progrès Méd.*, 1879, No. 31) relates the case of a patient, aged 40, who was received into the hospital on the 7th of January. He stated that, twenty days previously, he had a sudden rigor, with cough, difficulty of breathing, and acute pain in the left side, which compelled him to leave off work; it returned in the following day, although somewhat milder. His appetite was nearly lost, and he had bloody expectoration after the lapse of eight days. The left side of the chest was enlarged and immovable; from apex to base there was a dull percussion-sound, whilst the right side was everywhere sonorous. Blowing breathing was heard on the left side; the pectoral fremitus appeared very weakened, the heart was displaced towards the right. There was also slight œdema in the left chest, although the patient lay mostly on the right side. On account of severe dyspnœa, punctures were made on the 9th, 10th, and 13th, by which 1000, 1200, and 1500 grammes of fluid, containing much blood, were evacuated. There was almost no change in the physical state after the punctures; the subjective symptoms were indeed improved for a short-time, but the gain was only temporary. The patient sank visibly, soon began to be delirious, and died on January 22d. At the dissection, an effusion, with much blood, was found in the left pleural cavity. The pleura itself was covered with a hard membrane, two centimetres thick; the lungs were compressed to the size of a fist, and pressed against the vertebral column, and section showed them to be permeated with hard masses, apparently of a cancerous nature. On microscopic examination, the dense deposits on the pleura were seen to consist of organized connective tissue, fenestrated with numerous cavities lined with epithelial cells, so that at first sight the disease appeared to be alveolar cancer. The cells lining the wall were not everywhere cylindrical, but showed in some of the spaces a cubic appearance. The case was therefore essentially one of epithelioma (épithéliome métatypique, Malassez), the original source of which cannot be ascertained exactly. In the only case analogous to the present one, described by Malassez, a cancer had passed from the lungs into the pleura. In the present case, however, there was found in the lungs a less characteristic state, so that the possibility of the origin of the cancer in the pleura cannot be excluded. If this cancer belonged primarily or secondarily to the pleura, the clinical phenomena were highly characteristic; viz., the abundant hemorrhagic effusion, its speedy return after evacuation, the œdema of the thoracic wall, the bloody expectoration, and especially the slight change in the physical signs after puncture. Nothing but the acute onset of the chest-symptoms could lead to an error in diagnosis.—*Lond. Med. Record*, Aug. 15, 1880.

On the Curability of Attacks of Acute Phthisis (Galloping Consumption).

Dr. T. M. McCall Anderson, of Glasgow, at the late meeting of the British Medical Association read a paper on this subject, of which the following is a brief abstract.

By the term acute phthisis, the author meant an acute pulmonary affection, accompanied by high and continuous fever, running a rapid course, and leading invariably to more or less destruction of lung-tissue if the patient survived long enough. He recognized three varieties of the disease: 1. Acute pulmonary tuberculosis; 2. Acute pneumonic phthisis; 3. Acute pneumonic phthisis complicated secondarily with the development of gray miliary tubercles. He thought it impossible to distinguish the second from the third variety during life, but that the first might be suspected when the disease set in suddenly with high fever, great prostration, profuse perspiration, lividity, and great acceleration of breathing, and when these symptoms were *out of all proportion to the results obtained from a physical examination of the chest.* Having given extracts from the writings of Walshe, Trousseau, and others, showing that the profession was very hopeless as to such cases, he pointed out that, in a good many cases, he had obtained excellent results from treatment, of which the following was an outline; 1. Careful skilled nursing, with constant feeding, and stimulants in small quantities often (from 4 ozs. to 10 ozs. daily); 2. Each night a subcutaneous injection of $\frac{1}{100}$th to $\frac{1}{60}$th of a grain of atropia; 3. Remedies specially adapted to the removal of fever; (*a*) ice-cloths to the abdomen; (*b*) quinine, 10 to 30 grains, in a single dose, once daily; (*c*) a pill, composed of one grain of quinine, half a grain of digitalis, and from a quarter to three-quarters of a grain of opium, every four hours. In addition to this, special symptoms—diarrhœa, constipation, and the like—must be treated on ordinary principles, and, of course, the treatment indicated must not be used in a mere routine way, but adapted to the surroundings of each individual case.—*British Med. Journal*, Aug. 28, 1880.

Calcium Salicylate in the Serous Diarrhœas of Infants.

Dr. Alexander Hutchins, of Brooklyn, has treated in private practice, within the past three months, some twenty-seven cases of serous diarrhœa in infants, ranging from two months to two and one-half years of age, using calcium salicylate only; that some of the cases were seen but once, many only twice, and none above four times; that, in all, the disease is known to have been promptly and permanently controlled, justifies his calling attention to this method of treatment.

Whenever the dejecta were of the serous character, whether the flux was more or less profuse, in all the cases where the tendency is to cholera infantum, when collapse is to be looked for from excessive drainage of the serum, the calcium salt acted promptly in checking the frequency of the movements—ultimately in controlling them, and with a promptness and efficacy that the writer has never experienced by any other mode of treatment. The patients ranged in age from two months to two and a half years. No discrimination was made as to diet, which, in some instances, was breast milk exclusively, in others, condensed milk, the patent foods, or a mixed diet. In no case was any modification of the previous diet called for, save in the matter of quantity. All the patients were in good social and hygienic surroundings. In all cases the dose was 3 to 5 grains from 2 to 4 hours. The total quantity consumed by each patient varied between 6 and 18 powders. In a few cases minute doses of aconite and veratrum were given during the stay of the high temperature, and in other few, small doses of quinia were followed up after the subsidence of the disease.

It was noted that the medicine seemed to have no influence in changing the secretions so as to modify the character of the evacuations. The discharges would be under control for a time, say from 2 to 12 hours, and the next movement would be a watery one, but there would be no further recurrence of the diarrhœa. There might be a return to normal movements, or there might be a change to a diarrhœa of indigestion, or to a diarrhœa from irritation of the mucous surface, each of which would require some special interference. These sequelæ were exceptional, but in no case did the serous discharge recur.

It was noted, likewise, that this treatment necessitated very little interference with the usual diet of the child. It would be nearer the exact fact to say that no interference was required. In the majority of cases the discharges were so promptly checked that an indigestion did not occur.

It was further noted that the calcium salt had no appreciable effect on any one of the other forms of intestinal flux, whether lienteric or inflammatory. The serous diarrhœa alone seemed to be amenable to this drug. Each of the other forms required special treatment.

An additional fact was noted, that the vomiting accompanying these diarrhœas was controlled so soon as the medicine began to show its effect on the discharges. Certainly without exception the stomach tolerated the presence of the drug.

The medicine is administered by mixing the 3 or 5-grain dose in a teaspoonful of sugar, adding a few drops of water at a time till the whole is thoroughly moistened, and then thinning it with water so that it can be easily swallowed.

In the process of mixing the powder an effervescence occurs, which the prescriber recognizes as due to the release of carbonic acid in the formation of the new salt. Also in the process of mixing, a pungent odor of chlorine is not infrequently perceived.—*Proceedings of Med. Soc. of County of Kings*, Sept. 1880.

Surgery.

Malignant Syphilis.

Dr. Krowczynski, of Lemberg, enters at some length into the history of syphilis, and particularly of its more severe forms. He then relates the following case (*Vierteljahresschrift für Dermatologie und Syphilis*, 1 Heft, 1880): An unmarried woman, aged 30, of healthy appearance and good muscular development, was admitted into the hospital on November 4, 1875. The patient stated that her present illness began in October, and followed intercourse with a man who was afterwards ascertained to be suffering from syphilis. On examination, two indurated sores were found in the neighbourhood of the commissure. Both labia were œdematous, and the inguinal glands were enlarged, hard, and free from pain. There was also a white discharge from the uterus. A lotion of sulphate of copper for the sores, and a vaginal injection, were ordered. The ulcers soon began to spread, and were dressed with powdered camphor. On the 8th November they had united, forming a large horseshoe-shaped gangrenous sore. The inguinal glands became larger and tender on pressure. The strength decreased, and on November 20 shivering took place with a temperature of 100.4° Fahr. Nov. 21.—Temperature, morning, 101.8°; evening, 102°. The temperature remained above 101.4° until Dec. 9, on which day there was a violent shivering fit, with headache, pains in the limbs, and general malaise. The spleen was enlarged. The urine was free from albumen. On Dec. 10 a general measles-like rash appeared. Temperature, morning, 101.8°; evening, 131°. The ulcer of the genitals remained as before. During the following six days the temperature was always below 101°. On the 15th shivering again occurred, the evening temperature being 103.5° Next day the eruption had become papular, the papules being about the size of a lentil. The temperature during the following ten days fluctuated between 100.4° and 101.4°. On Dec. 25 there was a third attack of shivering, the temperature rising to 103.5°, and a red halo was noticed round each papule. Vesicles and pustules now appeared on the skin, and the temperature fell to 100.8°. The pustules ruptured, and left small ulcers. On Jan. 15, 1876, the ulcers were of the size of half-crowns, but the general condition had slightly improved. The general ulcer remained as before as to size, but was cleaner, and granulations were springing up at the edges. The patient from this time improved steadily; the temperature fell to 100°. The appetite returned, and the ulcers on the body began to heal. On March 27 the primary sore was healed. On April 3 syphilitic patches on the palatine arch were noticed for the first time. The ulcers of the skin healed, but left raised hypertrophic scars, which soon afterwards broke down into ulcers. The subsequent cicatrization occupied some time. No further relapse took place after this; but the patient remained in the hospital until January 4, 1877, by which time she had completely recovered. The man from whom she had contracted syphilis was now traced, and was found to have suffered very mildly, condylomata on the genitals and in the throat having been his only symptoms.—*London Med. Record*, Aug. 15, 1880.

Removal of Encysted Tumour from Conspicuous Positions without leaving any mark.

Mr. Philip Foster, of Leeds, states (*Med. Times and Gaz.*, Aug. 7, 1880) that this kind of tumour may, unless very firmly adherent, be easily removed by making a small incision into the cyst only just large enough to allow its contents to escape, completely emptying it by pressure, and then seizing its edges, which will be seen to project, and drawing it out. Even should a portion of the cyst be left, in all probability the tumour will not reappear. When unable to get away any part of it, I have succeeded in effecting a cure by scarifying its interior, and so setting up adhesive inflammation. Three or four days after these operations not the slightest mark or trace of their having been performed can be detected.

Scarification as a Remedy in Skin Diseases.

Mr. MALCOLM MORRIS, Joint-Lecturer on Dermatology in St. Mary's Hospital Medical School, believes (*British Med. Journal*, Aug. 7, 1880) that multiple linear scarification deserves more notice, as a remedy in certain forms of skin disease, than has yet been bestowed upon it. In as far as concerns the application of it to port-wine marks, suggested by Mr. Squire, he has found it to be practically valueless, owing to the length of time required to produce any visible alteration or improvement; nevertheless in acne rosacea and in lupus erythematosus he thinks that Mr. Squire's system of multiple linear scarification shows an advance on the old method of operating with a single scalpel, advocated by Hebra and Volkmann.

Short-Sight and School-Books.

According to M. JAVAL (*Bulletin de l'Académie de Médecine*, No. 44) three factors contribute towards the production of myopia in school-children: 1. Organic predisposition; 2. The influence of the medium; 3. The nature of the objects to be looked at. The first factor cannot be modified; the influence of the second can be diminished by suitable lighting of the class-rooms, though not without considerable expense; as regards the third, it is desirable that the employment of defective type in books for public schools should be prohibited. Type for young children should be large, and should gradually decrease in size according to the increased age of the scholar.—*London Med. Record*, July 15, 1880.

Treatment of Cleft Palate.

At the last meeting of the German Surgical Congress in Berlin, Herr J. WOLFF showed a patient on whom he had performed uranoplasty and staphylorraphy with complete operative success, but, as generally happens, without improvement of the patient's speech. He succeeded, however, in having an obturator made, which could be inserted without reopening the palate, and which had yet made the speech normal, as has been proved by making the patient read. The obturator consisted of vulcanized soft India-rubber; it was hollow inside, and filled with air, and was consequently elastic and compressible, and allowed the co-operation of the muscles of the velum in pronunciation. The experience derived from this case showed the necessity of operating on the fissure of the palate in every case. Whilst, hitherto, there had always been a liability that it might be necessary again to cut open the newly-formed palate after a perfectly successful operation, in order to introduce Suersen's obturator, there could be no question now of such liability. The operation must in future be successful as regards speech, either directly or with the assistance of exercises in speaking, electricity, etc., or with the assistance of the elastic obturator.—*London Med. Record*, Aug. 15, 1880.

Singular Obstruction of Wharton's Duct.

At a recent clinic Prof. RICHET drew attention to a curious case in the person of a young man who, while eating some bread, was seized with a sudden lancinating pain, the tongue being so much raised by a swelling which took place under it that the patient could hardly speak. The nature of the foreign body which it was supposed to be in Wharton's duct was sought for in vain, when a day or two after the patient felt with his tongue the sharp point of some object. This could not be seen, but some days later a very minute fragment of straw was removed from the duct. This probably had been in the bread, and became introduced into the duct during mastication. In a well-known case of Robert's a bristle became engaged in the canal.—*Med. Times and Gaz.*, Aug. 28, 1880, from *Gaz. de Hôp.*, Aug. 17.

The Use of the Hot-Bath in Strangulated Hernia.

In a late paper Mr. EDMUND OWEN, of London, argued that since the days of Pott, Hunter, and Cooper, there had not been that marked improvement in the treatment of strangulated hernia which the introduction of chloroform ought to have insured; that those "surgical warriors" employed the hot bath, venesections, and the nauseating doses of antimony for the simple reason that they knew of no better way of obtaining muscular and nervous exhaustion; that they were doubtless well aware that such depressing treatment would not improve the chances of recovery of the patient who should eventually be submitted to operation. He confessed that he did not understand the precise physiological action of the hot bath in aiding in the return of a strangulated bowel; Mr. Birkett spoke of it as exerting a powerful but uncertain influence over the vascular, nervous, and muscular systems. Mr. Owen maintained that an anæsthetic would supply all the advantages which the hot bath could pretend to afford; that it was a direct means of economizing time; and that, last but not least in order of importance, it saved the patient and the tender bowel that desperate employment of the taxis which the steaming bath often seemed to suggest to the medical attendant, who, with his coat off and his shirt-sleeves rolled up to the shoulders, intended having a final try at reduction. Mr. Owen agreed with Mr. Bryant, who urged that the taxis should never be employed without an anæsthetic, and that, the reduction of the hernia failing to be accomplished, the operation should be at once performed. Although strongly inclined to do so, he would not argue that the hot bath should never be employed in the treatment of a large strangulated hernia; all that he could say was, that in such cases the manipulation might effect less serious harm, on account of the constricting force being distributed around a more considerable mass of tissues; but that, in the case of a small inguinal hernia, or of a femoral hernia, large or small, its use was unadvisable, whilst for a recent small strangulation it was positively harmful. In conclusion, he asked for an expression of opinion as to whether the routine employment of the hot bath in the treatment of strangulated hernia was not a superstitious and dangerous remnant of antiquated surgery.

Mr. JOHN WOOD (London) expressed his hearty concurrence in the views just expressed. He had long been of opinion that the use of the hot bath for strangulated hernia, instead of being beneficial, was positively injurious; and that on these grounds—that the application of heat caused the dilation of the gases in the bowel, enlarged the hernia, and increased the difficulties under which the operators laboured. He had been accustomed in these cases to the application of a bladder of ice for an hour.—*British Med. Journal*, Aug. 28, 1880.

Chancrous Folliculitis.

M. GOUGUENHEIM read before the *Société Médicale des Hôpitaux* a paper on this subject, which he had prepared in conjunction with M. Bruneau (*La France*

Médicale, April 14, 1880). The following are the conclusions arrived at by the authors. Chancrous folliculitis, or follicular soft chancre, is an affection which attacks most frequently the external surface of the labia majora. This lesion presents a pimply follicular character, which often causes it to be confounded with simple acute folliculitis. The follicular appearance may persist throughout, or it may disappear after a few days, the lesion taking the ordinary aspect of the simple chancre. The simple chancre is often coincident with the follicular chancre. Chancrous folliculitis often succeeds the simple chancre, but the converse may occur. Chancrous folliculitis may exist alone, independently of any other ulcer. Implication of the inguinal glands is rare. The chancrous follicle goes through its evolution in three of four weeks. The follicular soft chancre is inoculable; but inoculation, contrary to what nearly always happens in the ordinary soft sore, has presented in some cases a period of incubation of from eight to twenty days. The diagnosis of the affection, when unaccompanied by ordinary soft chancre is impossible without inoculation. Most cases reported by authors as simple acute suppurative folliculitis, without the test of inoculation, may be regarded as cases of chancrous folliculitis. The existence of simple acute suppurative folliculitis of the vulva is hypothetical. Secondary suppurating folliculitis may be merely a follicular soft chancre developing on syphilitic ground.—*London Med. Record*, Aug. 15, 1880.

Primary and Secondary Amputation.

Prof. Richet, in a lecture delivered at the Hôtel-Dieu (*Union Méd.*, July 8), made the following observations on the question of primary amputation etc.:—

"I think I ought to acquaint you with the reasons which determine me only very rarely to practise amputation immediately after great injuries, and only when my hand is forced. At all epochs surgeons have been divided in opinion as to which of these two procedures it is most advantageous to have recourse. As far as I am concerned, during the first third of my career I was a convinced partisan of the necessity of immediate amputation, and cannot therefore blame those who practise it at the present time with a conviction as strong as that which I then entertained. But I have gradually become converted to secondary amputation, and am now one of its most earnest defenders. The theory of immediate amputation appears, indeed, at first sight, very seducing. It would seem that a patient in whom a violent injury had torn the muscles and crushed the bones could only be the gainer by substituting for this tearing and crushing a clean and regular wound—in one word, a surgical wound. Unfortunately, the practical results do not agree with the theoretical view and reasoning. In the different hospitals in which I practised surgery at the beginning of my career—at the St. Antoine as well as at the St. Louis—I found the patients on whom I had performed amputation succumbing within the forty-eight hours. Malgaigne, to whom I communicated my want of success, told me one day that he had gone through the same experience, and this it was which determined him to investigate the results of these immediate amputations. He avowed that the statistics were frightful, and that the mortality attained the figure of 86 per cent. So elevated a mortality seems of itself sufficient to prevent a surgeon following this practice; but it is of interest to seek for its reasons.

"When an individual has undergone a violent injury, his nervous system is greatly shaken by it, his pulse is depressed, and his temperature notably lowered—in a word, he is suffering from what is known as traumatic shock. Not only is the temperature lowered, but the circulation is delayed to such a point that the soft parts soon assume a violaceous colour, and then become gangrenous, at least in places. Soon there supervene intramuscular tumefactions and subcutaneous emphysema, the precursor of sphacelus. There already exists in all these cases manifest disturbance in the two greatest apparatus of the economy—functional disturbance of the nervous system and of the circulatory system—and all of a sudden is added to these pre-existing disturbances the new shock of a mutilation. It is certain that a considerable moral depression, caused by the loss of a limb, is added to the physical depression; and this moral depression should be largely taken into account, owing to the chances of the failure of the operation. But this is not all. It will happen—not in hospitals, in which usually but slight resistance is offered to the propositions of the surgeon, but in private practice—that we meet with a refusal when we have declared that immediate amputation is necessary. What happens then? If the patient dies, it will be said that he must have died under any circumstances, and would have done so more quickly under the operation. But if he recovers—escapes, as it is called—which is not rarely the case, the surgeon and surgery will both become the objects of serious and painful blame, which is also a grievous thing. Even when the patient, as is sometimes the case, does not succumb very soon after the operation, you must still not think that he will be preserved from all consecutive danger. He will continue exposed to those purulent burrowings which so frequently follow the intramuscular sanguineous effusions. Then there are the muscular retractions and conical stump. Suppose, on the other hand, you decide for abstention, there will be necessarily a considerable number of cases prove fatal; but you may feel assured that these belong to the class of those for whom immediate amputation would certainly not have proved of any avail. Others, fewest in number, will traverse the first accidents with success. The nervous system recovers itself little by little, the circulation regains strength, and the temperature rises; and, as a consequence, two or three days afterwards, normal inflammatory phenomena begin to appear. Is this, then, the moment at which amputation will have the *greatest chance* of success? Not yet. Such, at least, was the opinion of Velpeau and of Roux, with which I entirely coincide. They never operated before the fifth or sixth day, and this also is my habit of proceeding. I may finish with an anecdote which may impress this practice on your memory. Questioned one day by a *confrère*, who asked me, pointing to a patient upon whom I was delaying the operation, 'What is your object in waiting in this case?' 'I am waiting,' I replied, 'until he asks me himself to operate; and that will not be very long, for he accustoms himself to the idea on seeing that it is no longer possible to save the limb. The operation will then become a deliverance, instead of a sacrifice—a sacrifice on which he would now not decide without repugnance.'"—*Med. Times and Gaz.*, August 21, 1880.

Fracture of the Head of the Radius.

Professor Bruns, of Tübingen, in an original contribution to the *Centralblatt für Chirurgie*, No. 22, 1880, on fracture of the head of the radius, states that this lesion demands more attention from surgeons than it has hitherto received, and ought to be included in the list of typical fractures, as its origin and the form of the fracture are characteristic and regular, and it is not of very unfrequent occurrence. In addition to one case observed by himself, the author has collected from surgical literature twenty cases in which the nature of the lesion had been proved on anatomical investigation. These numbers, however, it is stated, give no idea of the frequency of the lesion, since the diagnosis is frequently attended with much difficulty, and in some cases is impossible.

In this injury the joint is involved, and the fracture takes a vertical or oblique direction from the superior surface of the bone, detaching a portion of the head.

The lesion is quite distinct from transverse or oblique fracture of the neck of the radius, by which the head *in toto* is separated from the diaphysis. Of the former lesion there are two forms—incomplete and complete fracture. The incomplete fracture has been produced experimentally by Bruns, and five clinical instances have been observed by Malgaigne and other surgeons. In the incomplete form, the line of fracture commences at the discoid articular surface, in some cases nearer the periphery, in others nearer the centre, passes down the neck, and ends at a blind extremity, so that the fragment still remains attached by a bridge of bone. The broken surfaces sometimes remain in close contact, sometimes diverge, and are separated by a wide gap. This form of fracture may be a fissured one, the head having been broken into a number of fragments, each of which remains attached at its base. In a case recorded by Verneuil, there was a well-marked T-shaped fracture.

In complete fracture, a larger or smaller fragment is wholly detached in most instances from the anterior portion of the head, rarely from the lateral or posterior portions. In this form the head is rarely broken up into several pieces. If the fracture be limited to the head of the bone, it is purely intra-articular; the fragment lies almost free in the joint, being attached only by a portion of ligament. If the fracture involve both the neck and the head of the bone, it is partly intra-articular, partly extra-articular, and free mobility and displacement of the fragment are prevented by the annular ligament.

In five only of the twenty-one cases collected by Bruns, was fracture of the head of the radius an uncomplicated injury. These numbers, however, it is pointed out, do not really represent the proportion of complicated to uncomplicated cases; since, in consequence of the slight symptoms of the simple fracture, and the difficulty of its diagnosis, the injury may be readily overlooked, or its true nature mistaken. In most of the complicated cases, the fracture was made out by direct observation after the death of the patient through concomitant lesions, or on resection of the injured joint. The most frequent of the various complications of fracture of the head of the radius is fracture of the coronoid process.

The most frequent causes of the fracture are a fall on the flexed elbow or on the extended hand, and direct injuries from the fall of a heavy body, from machinery, or from a gunshot wound. In fracture from indirect violence, which is of more frequent occurrence, it is very probable that the lesion is produced through the corresponding portion of the lower articular surface of the humerus, the *eminentia capitata* being driven with such force against the discoid articular surface of the radius as to compress and break away a portion of the latter bone. The fracture, for anatomical reasons, is more likely to occur in the extended than in the flexed position of the forearm. In full extension, the posterior half of the articular surface of the head of the radius is free, and projects posteriorly beyond the end of the humerus, the full force of which, in case of a fall on the hand, is applied wholly to the anterior half of the radial articular surface. In flexion of the forearm, the whole of the upper surface of the radius is in contact with the articular extremity of the humerus. The opinion of Bruns as to indirect fracture of the head of the radius being the result of force acting with the forearm in an extended, and not, as is supposed by some, in a flexed position, is confirmed by the fact of the frequent occurrence, as a complicating lesion, of fracture of the coronoid process, which injury, as has been proved by the investigations of Lotzbeck and Urlichs, is almost always the result of a fall on the over-extended hand and forearm.

Bruns has succeeded in producing the fracture experimentally. On striking with much force the head of the humerus in a removed upper limb, the forearm being extended, and the palm of the hand applied to the ground, he has twice produced a fissured fracture of the head of the radius, and once a fracture, with detachment of its anterior portion. It is mentioned, however, that Von Lesser and Urlichs have effected a like result with the forearm of the detached extremity flexed at a right angle.

It is believed that, if the attention of surgeons in future be directed to this lesion, its diagnosis on the living subject will become more exact. Some help will be given by a clear history of the way in which the injury was produced, and by the presence of such a complication as fracture of the coronoid process. If a portion of the outer margin of the head of the radius have been broken off, a movable fragment of bone might be felt, and at the same time, with alternate movements of supination and pronation, crepitus might be made out. In an instance of incomplete fracture, with a wide gap between the partly detached fragment and the head of the radius, the end of the bone will feel as if enlarged, and present an abnormal prominence. An injury of this kind is very liable, as was shown in a case recorded by Malgaigne, to be mistaken for incomplete luxation of the head of the radius.

From seven of the author's collected observations, information was derived as to the usual mode of healing after fracture of the head of the radius. In three instances there had been osseous consolidation with some dislocation of the small fragment; in one case upwards, in another directly downwards, and in the third case outwards. In one case, the fragment had united with the coronoid process. In each of the remaining three cases, the fragment had been converted into a free articular body.—*London Med. Record*, Aug. 15, 1880.

Diagnosis of Fracture of the Neck of the Femur.

Dr. BEZZI draws attention, in *Lo Spallanzani*, Nos. 1 and 2, 1880, to a sign which is pathognomonic of fracture of the neck of the femur, but which is not generally known. In examining the space between the trochanter and the crista ilii, it will be found that while, on the sound side, the muscles occupying this region (the tensor vaginæ femoris and the gluteus medius) are tense, and offer to the hand a considerable feeling of resistance, they present on the affected side a deep, well-marked depression, a flaccidity and diminution of tension, from displacement upwards of their points of insertion.—*Glasgow Med. Journal*, Sept 1880, from *Centralblatt f. Chirurg.*, July 31, 1880.

On the Mechanism of Gunshot Fracture of the Long Bones.

At the meeting of the German Surgical Congress in April last, Dr. BORNHAUPT, of St. Petersburg, read a paper on this subject. It was an extract from a larger work in the Russian language, having reference to Reyher's collection of preparations of gunshot fracture. Herr Bornhaupt assumed that real perforating gunshot wounds of bone are rather rare; they are mostly complicated with fissures, which, however, are less the result of commotion than of a direct action of force. The most simple case is the wedge-like action on the epiphyses, in which the fissures, issuing from the track of the shot in the bone, may extend perpendicularly upwards and downwards, without perforating the articular cartilage. Such fissures are more or less frequent, especially when great force is applied, i. e., when the channel made by the shot is long. The explanation of the forms of fracture in the diaphysis is more difficult. They sometimes resemble a stick bent in its longitudinal axis; or a ring, compressed from two opposite sides. In the first case, there may be simple transverse fractures (mostly through spent bullets), in the second, two, three, or four longitudinal fissures. If the diaphysis be injured more towards the middle part, then the two mechanisms combine in the production of a typical form of fractures, viz., of the "spiral longitudinal fracture." The bone divides into four fragments; in addition to an upper and lower, two triangular splinters are to be found opposite the part which has been struck, forming what Bornhaupt calls the posterior longitudinal fissure. He thinks that, when the bullet has not hit directly the posterior wall of the bone, the longitudinal fissure originates through direct force, and not through the hydraulic pressure of the marrow. As the proof of this, as well as of the following statement, he described experiments on a glass cylinder, and showed that the typical fissures often do not occur in so distinct a form, and that, on the contrary, the bullet comes a second time into contact with the wall of the bone, and produces fissures of exit with many, often forty or fifty splinters, extending through more than half the length of the diaphysis. Herr Bornhaupt had never seen healed fractures of that kind in the femur, to which principally his discussion referred. In less firm, but more inflexible bones, the circumstances become more complicated; they may, however, be traced always to compression, and not to commotion. The further comparison with the splintering of glass, as well as the consideration of the histology of the spongy tissue described by von Ebner. prove that it depends on the manner in which the force is applied, whether the brittleness or the fissibility of the bone is affected; whether the bone breaks like glass, or splits like wood. Spiral fractures were explained as resulting either from embryonic torsion of the structure of the bone, or according to Koch and Filehne, from a twist at the moment when the force is applied. In conclusion. Herr Bornhaupt discussed the reaction which the bone-splinters exercise on the form of the bullet, the increase of the destruction by the latter and other subordinate factors, as, for instance, the presence of pieces of ammunition, which form at the same time centres of infection, and the secondary fractures of the primary splinters, for the study of which he most earnestly recommended experiments on fresh preparations.

Herr VON MOSENGEIL (Vienna), differing from the author of the paper, pointed out circumstances in which a simple perforating fracture, admitting mostly of a favourable prognosis, might occur. He further laid stress on the differences which the quality of the material of the bullet produces in the kind of fracture.

Herr VON LANGENBECK opposed the conclusions which might be drawn from the statements of Herr Bornhaupt, against the possibility of *débridement* in extreme cases of splintering of the humerus and femur. He thought that, if in such cases the wound were laid open very early, and the loose splinters extracted, it was possible to save the limbs and life of the wounded, especially if materials for antiseptic dressing were at hand.

Herr BORNHAUPT thought that a distinction must be made, whether the bullet had struck one or both walls; in the latter case, one could not think of saving the limb, on account of the extent of the destruction, and in the former, one could not think of extraction on account of the size of the splinters.

Herr VON LANGENBECK said that might be correct as regards the femur, but not the humerus.

Herr BORNHAUPT admitted this. Recovery occurred in many gunshot fractures of the upper arm.

Herr VON LANGENBECK said that healing did not follow in all cases. He had been successful in a late extraction of splinters, but not in an intermediate one.

Herr SCHMIDT (St. Petersburg) stated his experience in the last Russian-Turkish war, regarding the healing of gunshot fractures without extraction of splinters. The latter was only necessary if sepsis occurred, but still there were many individual differences existent. The Turks especially resisted septic poisoning better than other nationalities.

Herr VON LANGENBECK was of the same opinion.—*London Med. Record*, August 15, 1880.

Midwifery and Gynæcology.

Measles in Relation to Pregnancy and the Parturient State.

From a study of the literature of this complication of pregnancy and parturition Mr. CHARLES E. UNDERHILL (*Obstetrical Journal of Great Britain*, July, 1880) finds it to be a rare complication of this condition, due probably to the fact that most adults are protected by an attack of the disease during childhood, but that when it occurs in pregnancy it is a very serious occurrence, and is a frequently fatal complication of both pregnancy and parturition. Mr. Underhill believes measles to be most fatal when it comes on soon after delivery, while those who are confined during the course of the disease stand a much better chance of surviving it.

Secondary Syphilitic Affections of the Vagina and Uterus.

M. MARTINEAU devotes a clinical lecture, reported in *L'Union Médicale*, May 13 and 16, 1880, to the consideration of secondary affections of the vagina and uterus, and refers to five cases which were in the Hôpital de Lourcine under his care. Vaginal and uterine syphilides are rare. Among 522 women with syphilis of the vulva, Fournier found twenty-five cases of cervical, and nine of vaginal syphilides. According to Martineau's experience the lesions are situated with almost equal frequency on the cervix uteri and vagina; of the five cases the vagina was affected in two, the uterus in one, and in two both uterus and vagina were involved.

Syphilides of the Vagina may be situated at the vulvo-vaginal orifice, or on the posterior or anterior vaginal wall. About the vulvo-vaginal orifice erosions and ulcers are seen; papules are more rare. When situated on the posterior vaginal wall the lesion is nearly always papular, and appears as a small round or oval papule of the size of a pin's head to that of a lentil, red, grayish, or whitish in colour. The number of the lesions varies usually between four and six, but there are occasionally more. In one case there were fifteen papules. They appear usually about the eighth week after the commencement of syphilis, but exceptions are numerous. Only two out of the five cases corresponded to this period. In the others, the lesions appeared later, viz., eight months and one year after the initial lesion. There is great difficulty in fixing the exact time of appearance, because the initial lesion in women often goes unnoticed. The syphilides also occur unknown to the patient and disappear without complication.

Syphilides of the Uterus may be erosive, papular, or ulcerating (the author has never seen roseola of the uterus). The erosions appear as small defined lenticular shallow ulcers. The papules present almost the same characters as elsewhere, viz., small projecting oval or elliptical disks from the size of a lentil to that of a 20-centime piece; smooth on the surface, opaline or white, sometimes isolated, sometimes agglomerated, and may be situated on any part of the cervix. The ulcerating syphilides are often confounded with the ulcerations of metritis. The syphilitic ulcerations are shallow, are seated near the os, especially towards the centre, and have a smooth non-granular surface. These syphilides are indolent, and pass unnoticed by their bearer, the physician only discovering them when he looks specially for them. They do not usually give rise to metritis, though this is a very common complaint in syphilitic women. M. Martineau and his pupil M. Fourcault have described under the name of "*exulcerative hypertrophy of the cervix*" a lesion of the uterus which, according to them, appears during the evolution of secondary manifestations elsewhere. As M. Martineau has never met with this, he thinks it must be very rare, if even it ever exists.

Diagnosis.—This is sometimes difficult. The erosions due to syphilis are lenticular, single or multiple, coppery red, contrasting sharply with the surrounding mucous membrane, exist independently of vaginitis, and may be situated on any part of the cervix. The erosions due to vaginitis, on the contrary, have a very bright red colour, are voluminous, bleed easily, are irregular, are often seated at the base of the cervix where it joins the vagina, and extend often over the whole of one portion of the cervix. There are, moreover, the physical and functional signs of vaginitis. The lesions caused by metritis exist generally on both lips around the os; they are granular; they appear at first as projecting inflamed follicles with a whitish apex, and afterwards become characteristic erosions. Uterine syphilides, from their opaline tint, might easily be confounded with the diphtheroid chancre of the cervix, described by M. Bernutz. This, however, is a large superficial ulceration of the size of a franc piece or even larger, covered by a grayish false membrane; it is non-infecting, auto-inoculable, and unaccompanied by other signs of syphilis. Secondary syphilides of the cervix may also be confounded with herpes and eczema. An attentive examination will, however, discover in these latter affections, vesicles in groups in the case of eczema, or isolated in herpes, and also the small characteristic "collarette" will be seen at the circumference of the vesicles which have burst.

The *Prognosis* is very favourable. The lesions disappear with or without treatment. They are of importance, however, because they are a frequent cause of contagion, and are often overlooked, or mistaken for some other affection.—*London Med. Record*, August 15, 1880.

Total Extirpation of the Uterus from the Vagina.

KALTENBACH reports (*Centralblatt für Gynakologie*, No. 11, 1880) the case of a lady, aged 57, who had ceased to menstruate for five years, and had suffered from uterine prolapse for twenty-four years. All sorts of means adopted to restrain the prolapse had failed. In February of the present year she applied to Dr. Kaltenbach for the relief of urinary and other persistent trouble occasioned by the persistent prolapse. The uterus, vagina, and bladder were completely external. The sound passed five inches into the uterus. The anterior and a portion of the posterior lip were occupied by well-defined, copiously secreting ulcerated surface. The patient readily agreed to the proposition of an operation for radical cure. The original intention was to remove the ulcerated cervix along with its vaginal attachment. For this purpose a ligature was passed on each side so as to include the uterine arteries, and a portion of the neck about 2–2½ inches long was dissected out. In executing this manœuvre, however, the operator went too far, and opened into the peritoneum high up posteriorly. This accident suggested to him the total extirpation of the uterus. He accordingly passed two fingers through the rent and pulled the uterus down through the peritoneal opening without trouble. The uterus now hung isolated, attached only laterally by the somewhat twisted broad ligaments, and anteriorly to the bladder by the peritoneal reflection. The two ligaments were now ligatured, each in three portions, and inside the ligature the uterus was separated by a stroke of the knife. The plica vesico-uterina was seized by small forceps on both sides and cut through in front of these. Although the cords in the broad ligaments were very firmly tied, the middle ligature on the right side was seen to be defective. The corresponding part of the broad ligament became retracted, and there resulted considerable hemorrhage. By opening out the forceps fixed in the peritoneal wound edge, the bleeding part was easily exposed and definitely secured. Care was now taken, by introduction of small pieces of sponge fixed in holders, to make sure that no blood had entered the peritoneal cavity. The peritoneal wound was now closed up by six silken sutures, left long, and which at the same time fastened the ligatured portions of the broad ligaments in an extra-peritoneal position. In order to hasten the arrest of hemorrhage the lateral portions of the vagina were brought together with deep sutures, leaving only the central part of its lumen open. The inverted vagina, only now about one-third its original length, was covered with thymol wool and kept in position by a T-bandage. The operation was completely successful. The ligatured portion of the broad ligaments and a portion of the vaginal wound sloughed off. The prolapsed vagina became spontaneously replaced on the fourteenth day. After four weeks the opening in the vagina was completely closed by a smooth cicatrix. After the woman began to walk about the vagina again prolapsed. This inversion was, however, on the 20th March, cured by a kolpo-perineoraphe, which was executed at a single sitting. The author proceeds to suggest that this operation may ultimately find wider applications, so as to replace other more serious measures suggested for the cure of severe prolapse, complicated or uncomplicated. The advantage which he claims for the operation are the elevated situation of the opening into Douglas's space, the shutting up the peritoneal wound by means of suture, and the retention externally of the ligatured stumps of the broad ligaments. By the former arrangement the danger of opening the bladder or including the ureters in the ligatures are obviated. By the second arrangement it is possible to apply antiseptic measures to the extra-peritoneal wound; and by the third a free exit is allowed for the ligatures and any necrobiotic structures that are separated from the vaginal wound while it is healing.—*Edinburgh Med. Journal*, Aug. 1880.

A Contribution to the Operative and After-treatment of Amputation of the Supravaginal Uterus in Fibroma.

This is the title of a paper by Dr. DORFF, Assistant-physician to the Gynæcological Clinique in Freiburg, contributed to the *Central. für Gynakologie*, No. 12, 1880. It gives an account of eight cases in succession in which, by Hegar or by Kaltenbach, the uterus had been removed on account of fibroid tumors, all of which were successful, and all had been treated since August, 1879. The author objects to Pean's extra-peritoneal method as hitherto practised, on two grounds: first, that it is usually not, or at least not completely, extra-peritoneal. Only when the cervix is very mobile or very long does it permit of being so far drawn out as that the ligatures lie in front of the abdominal wall. In other cases they lie between the edges of the abdominal incision, and even in the peritoneal cavity, beneath the serous membrane. The second objection to the Pean method is the usually rapid onset of decomposition in the stump, and the great difficulty of keeping it antiseptic. To avoid the first difficulty Hegar stitches the peritoneum close to the stump below the ligatured point, so that the stump comes to project free from the bottom of a short conical or funnel-shaped cavity, the sides of which are formed by the thickness of the abdominal wall, and communication with the peritoneal cavity is completely shut off. To avoid sepsis in the stump, Hegar, partly by experiment on animals, partly by observation of operation cases, has arrived at the result that the stump can only be kept securely aseptic by dryness and keeping away of every kind of moisture. This end is effected in these operations, first, by the most careful arrest of bleeding in the abdominal incision; secondly, the stump itself, on its cut surface and on its peripheral aspect, is cauterized as deeply as possible with Paquelin's cautery. Then the edge of the abdominal incision on the lateral walls of the funnel-shaped cavity is painted over with a 10 per cent. solution of chloride of zinc, the excess of solution being carefully dried up, immediately after the painting, with small balls of cotton-wool. The bottom of the funnel is avoided in this process, and a weaker solution employed for it. Small rolls of absorbent wool, which have been steeped in a weak chloride of zinc solution (1–2 per cent.) and then dried, are pushed between the stump and the edge of the wound, and the cavity thus carefully filled. The rest of the dressing must be so arranged that one may examine the stump and surroundings at any time without disturbing the dressing. If the rolls of cotton-wool are moistened with blood or wound fluid, we may be sure that decomposition is sitting in rapidly. The unpleasantness in this treatment is the sloughing off of the edges of the abdominal wound and its surroundings. This slough begins to come away from the 6th to the 7th day. Hegar and Kaltenbach have not seen any bad results from it. After the 5th or 6th day the chief dangers are over. These operators do not now employ Pean's ligature, but the elastic ligatures recommended by Kleeberg in Odessa for fibroma operations. A short account of the eight cases is then given.—*Edinburgh Med. Journal*, Aug. 1880.

Diastases in the Bones of the Lower Extremities of the Fœtus, produced by the Accoucheur.

In the *Edinburgh Medical Journal*, for June, Professor SIMPSON has an article on this subject. In a case of turning for placenta prævia, the child being dead, he had an opportunity of making a dissection of one leg in which the only external appearances of injury were a slight abrasion over the internal malleolus and an undue mobility of the ankle-joint, as if some of the ligaments had been torn through. "Yet at three different points fractures were found on dissection. They were all fractures of the kind known to surgeons as 'diastases'—the shaft of the bone, that is to say, had become detached from the epiphyses. The seats of the diastases in the right leg are, 1st, the upper end of the femur below the trochanters; 2nd, the lower end of the tibia; and 3d, the lower end of the fibula. There has also been some separation of the epiphysis of the lower end of the femur, but the upper ends of the tibia and fibula are quite firm. In the left leg the epiphysis of the lower end of the tibia is loosened, but the epiphyses at both ends of the femur are firm." Dr. Simpson was led to make this examination from reflecting on a case which he has already published of a similar kind, except that the child was born alive. The left leg was found on the day after birth to be greatly swollen, with abrasions of the skin above the malleoli, and the limb hung stiffly from the pelvis. At that time he believed there was no injury to the bone or joint, but some laceration of the muscles and vessels. He is now inclined to think there may have been some fracture similar to that referred to. He would recommend in every case of turning, an examination of the limbs of the child, especially if there had been considerable traction exercised. If there be complete separation between apophysis and diaphysis, and the periosteum lacerated in the entire circumference of the bone, the hiatus will be easily traceable and crepitation may be felt. When there is simply loosening of the epiphysis the diagnosis will be more difficult as crepitation may not be perceptible. In the latter case nothing will be required beyond seeing that the limb is kept as much as possible at rest, but should the periosteum be lacerated, it will be necessary to bandage the limb to keep the separated portions of bone in apposition.—*Glasgow Med. Journal*, Sept. 1880.

MEDICAL NEWS.

COLOUR-BLINDNESS AS A PRACTICAL QUESTION.

Colour-blindness is no longer merely a scientific curiosity, but has become one of the practical questions of the day. Its discussion, instead of being confined to philosophic treatises and occasional articles in medical journals, has been taken up by medical societies, legislatures, corporations, and even political meetings, and the daily newspapers frequently give it a place in their columns.

Whatever may be thought of the merits of this question, or of what should be done in reference to it, there can be no doubt that its importance is at last recognized, and that it is receiving that thorough "ventilation" which is pretty sure to be followed by favourable action when the rights and interests of the public are concerned. This is due to the determined and persistent efforts of a few earnest men, such as Holmgren, Donders, Favre, and others abroad, and Dr. Jeffries in this country. The most rigid conservative or the most persistent obstructive will hardly now claim that some means should not be taken to protect the travelling public against the dangers that may arise from colour-blindness in those to whose care their lives are entrusted.

Everybody knows that the use of red and green signals is universal, both on land and sea, and that, particularly at night, the prompt and correct interpretation of these signals is the only security against collisions and other accidents; and it is now an established fact—established by observations at least as extensive, reliable, and positive as those upon which most of the facts by which we regulate the conduct of our lives are based—that about four per cent. of our male population are colour-blind; and colour-blindness is also a frequent symptom of various diseases of the optic nerve. It is too plain for argument that we have here to deal with a real danger, and not with a mere whim of scientific enthusiasts. Another danger, scarcely less important, is that arising from deficient acuteness of vision resulting from errors of refraction or diseases of the eyes.

It is of interest to know what is being done with this practical question. Government regulations have been established in nearly all European countries. The English government has not yet passed any law upon the subject, but some of the most important roads have instituted examinations on their own account. The army, navy, and marine hospital departments of our own government have each taken some action in the matter, though no uniform and definite standard of requirements has been established. An order of the Secretary of War requires that all accepted recruits shall be examined for colour-blindness by Holmgren's tests, and any defect observed noted on the descriptive list of the soldier. Such defect is not considered a cause for rejection, but disqualifies for service in the signal corps. An order of Surgeon-General Wales directs a similar examination, by medical officers of ships and stations, of all persons in the navy. In the merchant marine the government enforces the examination of pilots only. The Treasury Department has ordered that all persons applying for an original license, or for a renewal of license, as pilots on steam vessels shall be tested for colour-blindness. Every applicant for original license must present a certificate from a surgeon of the marine-hospital service, but pilots employed at points remote from marine hospital stations may be accepted on the certificate of any respectable physician of their neighbourhood. As this neighbourhood is likely to be a fisherman's village, the requirement is not an exacting one. Visual examination is not compulsory with any other class of seamen. Marine-hospital surgeons are required to examine, free of expense, any seamen who may be presented to them; but their labours have not been materially increased in consequence.

It will be noticed that, while our government has taken some important steps in the right direction, there is still a want of concurrence between the different departments, which have acted separately and partially, without any common plan or any fixed standard of requirements as to the necessary degree of visual acuteness and colour perception. The necessity of concurrent action in a matter of so much importance is evident; not only between the different departments of our own government, but between different governments, as the seas are the common highways of all maritime nations, and their safe navigation is a question of international interest. A petition in favour of such action, signed by Dr. Jeffries, and a number of ophthalmic surgeons and prominent scientific men, was presented to the last Congress. It was referred to the Naval Committee, who reported in favour of the appointment of officers of the diplomatic and consular service, and of the navy as commissioners, "to attend and represent the United States in any international congress held to consider and act upon said subject." A bill to that effect will be brought up at the next session of Congress.

At the instance of Mr. Bowman, the following resolutions have just been passed by the ophthalmological section of the British Medical Association, and forwarded to the British government and to the Milan Congress:—

"1st. That it is most desirable to establish international standard tests of visual acuteness and colour perception by means of an international commission, to which the several governments should be invited to send delegates.

"2d. That in all countries, persons upon whom may devolve the charge of life, by sea and land, where signalling is employed, with or without the use of colours, should be required to submit themselves to such standard tests of their sight, both before being admitted to their several services and also at stated subsequent intervals.

"3d. That an important part of the duty of such an international commission should be to devise some common system of signalling, especially for sea-going ships and for all coastwise; and that the standard tests should be decided on with special reference to such common system of signalling."

So much for the prospect of national and international action. The only one of our State governments that has taken any steps in the matter is Connecticut. She is the pioneer, and on her ground this new battle of civilization is just now being fought. An act was passed last March directing the State Board of Health "to prepare rules and regulations for the examination and re-examination of railroad employés in regard to colour-blindness and visual power;" and to recommend annually to the Governor, for appointment, two or more medical experts to make these examinations. Every railroad in the State is required to cause its employés to be examined before the 1st of October, 1880, and is rendered liable to a fine of not less than $200 or more than $1000 for employing any one after that date who does not hold a certificate of freedom from colour-blindness and possession of normal vision.

The Board of Health, in whose hands the matter is thus placed, have adopted substantially the standard of requirements agreed upon by the International Medical Congress at Amsterdam in 1879. Railroad employés are divided into two classes. Engineers, firemen, and brakemen form the first, and all others are included in the second. A certificate for the first class requires—1st. Healthy eyes and eyelids, without habitual congestion or inflammation. 2d. Unobstructed visual field. 3d. Normal visual acuteness. 4th. Freedom from colour-blindness. 5th. Entire absence of cataract or other progressive disease of the eyes.

For the second class—1st. Healthy eyes and eyelids, without habitual congestion or inflammation. 2d. Unobstructed visual field. 3d. Visual acuteness at least equal to three-fifths without glasses, and normal with glasses in one eye; and at least one-half in the other with glasses. 4th. Freedom from colour-blindness in one eye; colour perception at least equal to three-fourths in the other eye.

These requirements may be modified by the board in the case of old employés who have held their positions for five or more years. There is no provision for re-examinations at stated intervals, but re-examination is required—1st. After any disease of the eyes. 2d. After injuries affecting the head or eyes. 3d. After any disease or trouble of the brain, and after long-continued illness, as typhoid fever. 4th. After mistakes or acts which call in question the visual powers; also whenever directed by the Board of Health.

There is certainly nothing monstrous or unreasonable in these provisions. Few of us would care to trust our lives on a stormy night to an engineer who could not distinguish *promptly* between red and green; and fair average sight is all that is required by the tests for acuteness of vision. But colour-blind trainmen are not blind to their own interests, and before half a dozen cases had been detected they stirred up their friends to hold mass meetings, circulate petitions, and employ counsel. Unfortunately, a Presidential election is near at hand, and among these 3000 Connecticut railroad men there is "a possible" 120 of colour-blind voters, to say nothing of those whose vision may be defective from other causes. Therefore "the two *great* political parties" have rushed to the rescue, and, vying with each other in their patriotic efforts to oppose the law, have raised a "tempest in a teapot," which would be funny if it were not rather degrading. They clamor for "practical tests by practical men." This means the waving of flags and lanterns, which has been proved to be *practically* almost worthless. It has been shown, over and over again, that a colour-blind person may make very intelligent and, under *favourable circumstances*, generally correct guesses at the colour of these flags and lanterns, particularly if his eye has been trained to observing them for years. He does this by means of the difference in the *intensity* of light, his perception of which has been unusually developed in consequence of the absence of the colour sense—just as the hearing of the blind becomes more acute. Such guessing, however, is not a safe guide where life or death depends upon the correctness of the guess, especially as the intensity of a light varies with atmospheric and other conditions, and its perception is affected by the varying states of the eyes and of the general health. This fact seems to have been had in view by the committee of protesting engineers when they stipulated that the tests should be made "under fair conditions of atmosphere." This makes things easy for the engineers, but is hard on people who have to travel of foggy or sleety nights.

The "pressure" seems to have been too much for the Connecticut Board of Health, who have halted their doctors in the midst of their work and directed them to make no more examinations until further orders. Policy would seem to dictate that these orders should not be given until after the election, when sober second thought may give a chance for honest conviction or harmless indifference.

At all events, Dr. Jeffries has succeeded in getting the thin end of his wedge pretty well in place; and, while he is perseveringly hammering away at it, he should have the aid of all who can help him drive it home.

Proceedings of the Fifth Annual Meeting of the American Gynæcological Society, Cincinnati, Sept. 1st, 2d, and 3d, 1880.

(Specially reported for the MEDICAL NEWS AND ABSTRACT.)

The fifth annual session of the American Gynæcological Society was held at Cincinnati, September 1st, 2d, and 3d, 1880. The Society was called to order by its President, Dr. J. Marion Sims, and upon the Secretary, Dr. Chadwick, calling the roll, about twenty (forty per cent.) of its Fellows were found to be present.

Dr. THAD. A. REAMY, of Cincinnati, a resident Fellow, delivered a brief and eloquent address of welcome, in which he congratulated the Society upon the high position in medical literature already occupied by the published Transactions of the body, and expressed the belief that they would continue to improve with each successive meeting.

The Proper Field for Battey's Operation was the subject of the first paper on the programme. Dr. BATTEY, the originator of the operation, did not present his paper in full, but gave the principal points which he intended to make in that publication. Among the different classes of cases chosen for it he mentioned cases of menstro-mania or ovarian mania, in which there could be no question as to its advisability. The mind in many of these cases is dethroned by reason of violent perturbations dependent upon stoppage of menstruation; the same accidents sometimes follow while menstruation is going on, but its functions are deranged, and its process accompanied by very severe pain. After removal of the ovaries in such cases profound changes in their structure are found, which are incurable by any internal administration of medicines. Cases of ovarian epilepsy form another rather numerous class of cases indicating the operation. The author here hoped that operators would exercise great caution in distinguishing cases of uterine from those of ovarian epilepsy. Cases of absence of the uterus, with more or less irregular ovulation, would often produce in the system such violent nervousness and local congestion, unrelieved by nature's assistance in the menstrual discharge, that he would not hesitate to remove the ovaries. He gave an example of another class of cases in which there was complete occlusion of the metro-vaginal canal, in which removal of the ovaries was very gratifying. Another class, which he acknowledged to be a very inexact and unscientific classification, includes cases of pernicious amenorrhœa in which all other plans of treatment fail. Some cases of interstitial fibroid tumours of the uterus, not amenable to the ordinary resources of our art, constantly subject the patient to the danger of death by exhaustive hemorrhages. The climacteric follows the removal of the ovaries, and the tumour gradually diminishes in size. Such has been the experience of Hegar, Lawson Tait, and a number of physicians of our own country. In certain incurable flexions of the uterus the extirpation of the ovary is justifiable. In conclusion, Dr. Battey strongly advised the removal of the ovary in every case in which an obstetrician is compelled to resort to the Cæsarean section on account of a contracted or deformed pelvis. He believed it criminal to subject a woman, upon whom abdominal section was once performed, to a repetition of a similar danger.

Anterior Displacement of the Ovary.—Dr. GEO. J. ENGELMANN read an account of two cases of anterior displacement of the ovary simulating inguinal hernia. This is a rare form of malposition, much rarer, indeed, than the lateral displacement referred to by Dr. P. F. Mundé in the last volume of the Society's Transactions. One of the two cases referred to occurred in a young woman of twenty-four, and had existed for seven years. She dated the beginning of her trouble from a fall. When seen by the author, after having been cared for by a number of physicians, mental delusion was showing itself in the form of melancholia. The second case was a woman of forty-six, whose nervous system was hopelessly disturbed. At no time except during the menstrual discharge did the lump appear. In the one case the ovary was removed. It was not enlarged. The patient recovered without a bad symptom. The removal of this one ovary brought on the menopause. She menstruated very slightly twice after its extirpation, but never after. Her melancholia disappeared, and she recovered completely. In his second case, instead of producing the menopause artificially, it was left to nature because of her age. He did not believe that a melancholia which had existed twenty-six years would be relieved by either menopause or the removal of the ovaries.

In the discussion which followed the reading of these two papers, Dr. **Fordyce Barker** stated that he had met with but three cases of anterior displacement of the ovary. He could not believe it possible for such an accident to be caused by a fall. He was inclined to consider the displacement congenital, but thought the fall might have aggravated the congestion and thus induced the nervous symptoms. His own treatment had been palliative, and his best results had been attained by the administration of hyoscyamia during the menstrual periods.

Dr. **Byford** stated that while he believed Battey's operation would be found a very useful measure in some cases, we would often be disappointed in its results. In some remarks upon the influence of removal of the ovaries upon interstitial fibroids of the uterus he referred to one case in which the fundus extended two inches above the umbilicus, and in which both ovaries were removed. As nearly as the speaker could recollect, this case had been reported by Dr. Trenholme, of Canada, as cured by the operation. That patient had been under the speaker's care for the past year, and her condition is about as miserable as it is possible to be. Of course, there is now no menstruation, but irregular congestions and hemorrhages occur in consequence of the least exercise or excitement. These sometimes reduce her almost to the point of death. The tumour now reaches fully as far above the umbilicus as it was described before the operation. Her condition now, therefore, although somewhat changed, is not improved.

Dr. **Sims** remarked that Battey's operation is now quite frequently performed by German surgeons; in England it has advanced quite rapidly within the past twelve months. Lawson Tait has been seized with a mania for its performance, having had twenty-eight cases in less than one year; he reports excellent results, but the accounts of these cases were, in the speaker's estimation, meagre and unsatisfactory. Sims had himself recently operated upon four cases. Two were now doing well; one died from the effects of bromide of ethyl, and the fourth was only partially benefited. He predicted a grand future for the operation after we have better learned how to discriminate the proper cases.

In concluding the discussion Dr. **Battey** said that in every instance in which he had removed both ovaries, the menopause had been established. If either be partially left, menstruation will continue to some extent. During menstruation we expect an increased flow of blood to the reproductive organs, hence an increased growth of any tumour present. By stopping this periodical congestion, we hope for and will often succeed in producing a gradual atrophy of the tumour. He expressed great fears that the operation might fall into disrepute through too great license in the selection of cases.

Ovariotomy Complicated with Pregnancy.—Dr. **Wilson** read a paper in which he discussed the question of what should be done with a large ovarian tumour existing with pregnancy. He objected to tapping on account of the necessity for its frequent repetition, and because each tapping is followed by new and strong adhesions to the adjacent organs. His statistics showed twenty-four recoveries out of twenty-nine operations undertaken under antiseptics, independent of any reference to the existence of pregnancy.

Dr. **Dunlap** was of the opinion that ovariotomy would be likely to induce labour, and labour occurring immediately after such an operation, would be likely to result fatally. He advised, therefore, that an abortion be induced, and that the ovariotomy be postponed until after recovery from the abortion.

Dr. **Chadwick** advocated the policy of non-interference whenever the ovarian tumour could be pushed and kept above the brim of the pelvis. He considered the dangers of non-interference much magnified, and cited three cases in which this let-alone policy had resulted very favourably.

Dr. **Byford** had been in the habit of frequently tapping the cyst in these patients, but said that the favourable statistics presented by Dr. Wilson went very far toward influencing him in favour of the removal of the ovarian tumour during pregnancy. He was utterly opposed to the mischievous practice of abortion in these cases. He mentioned one case in which an ovarian tumour of considerable size existed throughout two pregnancies without rupture and was afterwards successfully operated upon.

Dr. **Sims**, in the course of some remarks which agreed in the main with those of Dr. Wilson, referred to one case in which rupture of an ovarian cyst occurred during labour and the woman recovered. The same accident, followed by the same happy result, happened also in her next confinement. He felt satisfied that when the tumour becomes as large as a fœtal head, the better plan, in the majority of cases, will be to remove it.

Uterine Massage as a Means of Treating Certain Forms of Enlargement.—Dr. A. **Reeves Jackson's** paper on this subject opened with an account of the causes producing these enlargements; he spoke of the failure of most of the means hitherto employed in reducing these enlargements, and of the good results obtained from massage. Three kinds of massage are applicable in uterine diseases; abdominal, abdomino-vaginal, and abdomino-rectal. The first of these is the most satisfactory, but is applicable only when the fundus uteri extends above the pubes. The last variety is difficult of application, quite painful, and therefore of limited applicability.

Dr. **Reamy** had had no experience in the employment of uterine massage, but several points regarding it were far from clear to his mind. As used by Weir Mitchell, massage is employed to increase the strength and size of the muscular tissue in the limbs and elsewhere, not to reduce it. It may possibly be that massage, as employed by Dr. Jackson, promotes contraction of the muscular fibres in the engorged uterus. The length of time required, and the difficulty of obtaining the assistance of a competent person to carry it out, would, the speaker thought, be serious obstacles to the general adoption of this plan of treatment. Previous to its use it is extremely important that a correct diagnosis be made, and that pelvic cellulitis be excluded.

Dr. **Campbell** believed that the enfeebled circulation unattended with inflammatory conditions, for which Weir Mitchell used massage, would in an organ such as the uterus, leave the organ engorged with blood, therefore enlarged. The primal causes of these two states were the same. In each case, then, massage would stimulate the circulation and restore the natural condition and size of the organ.

Cataleptic Convulsions Cured by Trachelorraphy.—Dr. R. S. **Sutton's** contribution on this subject consisted in the narration of a case of lacerated cervix, in which the slightest contact with the point of laceration induced convulsions. Emmet's operation was performed and a perfect cure was the result.

Extirpation of an Encephaloid Kidney.—Dr. **Wm. H. Byford** reported the removal of an encephaloid kidney weighing four and a half pounds. The principal difficulty in the case was in the establishment of a diagnosis.

In the discussion which followed this report, Dr. **Chadwick** mentioned, as a point of possible value in diagnosis, the displacement forward of the colon in any growth involving the kidney.

Secondary Puerperal Hemorrhage.—Dr. **Parvin's** paper on this subject was a full discussion of the causes, symptoms, and treatment of this accident. He included under this head hemorrhage occurring from six hours to thirty days after parturition. Amongst the most potent of its causes, he included mental emotions, especially grief, and gave several illustrations.

The discussion unfortunately was not confined to *secondary*, but was largely devoted to immediate puerperal hemorrhage.

Dr. CAMPBELL, in some extended remarks, expressed the utmost reliance in iodine. When called to a serious case, he injects a solution composed of one part tincture of iodine to four parts of water. This, he claims, leaves no clot, produces no pain, and effects instantaneous contraction.

Dr. WILSON followed with some interesting remarks in which he advocated the use of the hand as a curette. The interior of the uterus should be freely scraped by the finger-nails.

Dr. BARKER expressed surprise that the author had not referred to malaria as a cause of these hemorrhages. He believed it to be a very potent cause. Iodine had not in his hands proved so successful as with a previous speaker. Hot water injections would often check an otherwise uncontrollable bleeding. He had often used iron but never with fatal results. On account of the character of the clot produced by it he would not again employ it except as a last resort.

Value of Quinia in Gynecic and Obstetric Practice.—Dr. H. F. CAMPBELL, in a paper on this subject, devoted himself to a refutation of the charge so frequently made against quinia, that its continued administration is liable to induce abortion. In his country—a very malarious one—it often becomes necessary to administer this agent in very considerable doses throughout the entire period of gestation, and the speaker has yet to learn of the first case in which it has exerted any of the ill effects attributed to it; indeed, he believed that its timely administration saved many a fœtus.

Dr. FORDYCE BARKER said that the influence of quinia in quickening and rendering more efficient labour pains, was what doubtless led to the incorrect belief in its harmfulness during gestation. He said that no healthy uterus will throw off a healthy fœtus. He had no doubt that the malarial poison tends to produce abortion, and agreed with the essayist in the belief that quinia often prevented it.

Drs. REEVE and PARVIN agreed perfectly with the statements made by the author of the paper regarding the innocuousness of quinia during pregnancy.

Dr. REAMY, of Cincinnati, said that quinia is not, in the true sense of the word, an oxytocic, yet in certain conditions and in a certain class of subjects—the leuco-phlegmatic—it will promote delivery; the circumstances under which it will have this effect are during the latter part of the first stage when the pains are frequent and inefficient, and the dilatation slow. Under such conditions, three ten-grain doses of quinia given at intervals of one-half hour, will slow the heart, reduce the fever, if present, cool the skin, lessen the frequency, and greatly increase the power of uterine contractions, rapidly promoting dilatation, and lessening the suffering of the patient. In cases not malarial he had frequently arrested a threatened abortion by moderate doses of ergot. In proof of this statement he gave a full comparison of the physiological effects of ergot and of such large doses of quinia as would be required under these circumstances. Those who will carefully select their cases will realize the result; but those who employ it as a promoter of parturient pains in all cases of inertia will be disappointed.

The Instinctive (or Natural) and Physiological Position of Woman in Labour.—Dr. GEO. J. ENGELMANN, of St. Louis, read only a portion of his paper, which is an exhaustive discussion of the subject of the position assumed by woman in labour. The essay showed very extensive research, and the author illustrated his descriptions of the peculiar postures of women, civilized and uncivilized, in ancient and modern times, by the presentation of a large number of well-executed drawings. As the result of his study of this subject, the author stated that the semi-recumbent position is the one most generally assumed during the most agonizing pains, and this is the one he would accordingly advocate. His conclusions were, therefore, that in the early stages the woman should be allowed to follow her own instincts as to position, and even in the later stages the same may usually be safely done with very slight restrictions. The semi-recumbent position appears to afford the greatest relief with the best effect, as it permits a free play of all the parts.

Dr. J. C. **Reeve** believed that whatever position a woman might assume early in labour, when the severe pains came on she would, if left to her own inclinations, assume the position on the back, with head and shoulders slightly elevated. This is the best position, with one exception—that on her knees—which in civilized life the woman is not likely to often assume. This, however, would bring the axis of the fœtus and uterus still more nearly in line with the pelvic axis.

Dr. **Campbell** cited a number of instances which convinced him that the natural position of woman in labour was the squatting position.

Three Fatal Cases of Rupture of the Uterus with Laparotomy.—Dr. W. T. **Howard**, of Baltimore, read a report of three cases in which this accident had occurred, and in which he had performed laparotomy. These three cases all proved fatal. In the future he would prefer to extirpate the uterus, as by this means a smaller surface would be left exposed to bleed and ulcerate. Statistics prove that extirpation of the uterus in such cases is not so frequently followed by death as is the simpler operation of Cæsarean section and removal of the child.

Drs. **Wilson** and **Parvin** agreed that Dr. Howard had indicated the correct rule of action in these cases. It might not always be necessary to operate if the rent be low down, involving the vagina; but whenever it occurs high up, the removal of the uterus is certainly the only proper procedure.

The Hot Rectal Douche.—Dr. J. R. **Chadwick**, of Boston, stated at the outset that the chief purpose for which this plan of treatment had been heretofore employed had been for the removal of impacted fecal masses. He cited a number of cases in which its field of usefulness had in his opinion been extended. Several of these were cases of diarrhœa dependent upon disease of the rectum and large intestine. A few applications of the hot rectal douche cured what a long-continued course of internal medication had wholly failed to influence. Previous to calling attention to the next class of cases in which it is useful, he demonstrated, by means of a number of Braune's plates, the very limited extent of peritoneal surface which it would be possible to influence by vaginal injections, as compared with the exceedingly large extent open to the influence of hot water introduced into the bowel. By this means the body of the uterus and the ovaries, as well as all the pelvic tissues, could have heat applied to them with only the intervention of the thin intestinal wall. Several cases were mentioned of burning pain in the ovarian region, and of other conditions following pelvic inflammation, so relieved. It is applicable in all cases except acute inflammatory diseases, and is, in the opinion of the author, incalculably superior to all other methods of applying warmth.

Dr. **Campbell**, in the course of some remarks in agreement with the essayist, expressed the belief that the hot water passed up into the small intestine and formed a sort of cushion about the pelvic organs. Being interrogated by Dr. Reamy as to its passing the ileo-cæcal valve, he said he had no doubt of the possibility of such an occurrence.

Dr. **Reamy** suggested that the water would lose its high temperature before it reached a very high point of the intestines. He contended that it was impossible, with the power exerted by the douche or ordinary syringe, to force water past the ileo-cæcal valve. The fact that all the water so injected does not pass off is no proof that it is carried into the small intestine, because a large amount of it is absorbed and enters the general system. It can never pass the valve in a mass.

Dr. **Chadwick**, in concluding the discussion, said, in reply to a question of Dr. Howard, that he had in two or three instances heard patients complain of hæmorrhoids; but these patients had probably suffered from them before. The use of the douche, by preventing the accumulation of feces, would obviate all danger of hæmorrhoids. He generally suspended the use of the douche during menstruation, not knowing what might be its effects. He failed to agree with Dr. Reamy that the same results could be obtained from poultices applied externally, because, as before shown, the application could never be so closely made. He also differed with Dr. Reamy regarding retrostalsis. He said that about one year ago he performed an ovariotomy after freely purging his patient. During five days subsequent to the operation he permitted no food to be given by the mouth, but supported her by enemata of beef-tea. Yet on the fifth day the patient vomited beef-tea. He believed that this beef-tea had passed the ileo-cæcal valve and had been carried upward by retrostalsis.

Ulceration of the Cervix Uteri.—Dr. **Thad. A. Reamy**, of Cincinnati, read his paper on the above subject only by abstract. The paper is founded on an examination of eight thousand women supposed to be suffering from uterine disease. By the ulcerative process and by ulcer the author means what is expressed by Paget and Billroth, and cited the following definitions:—

Ulcerative process usually the result of detachment of dead portions or molecules of inflamed tissue. . . . Substance removed, not absorbed, but ejected. . . . An ulcer usually begins by slough or detachment of dead tissue by removing layers of living tissue that surround it. (Paget.)

An ulcer is formed when by the above process the vascular and proper tissue (submucosa) is removed. (Paget.)

An ulcer is a wounded surface which shows no tendency to heal. (Billroth.)

Excluding syphilitic and cancerous ulceration, out of the total 8000 women examined, there were found but 19 cases of true ulceration.

A large number suffered from abrasions and erosions—so-called ulcers.

The widely-extended disagreement between physicians as to the prevalence of ulceration is attributable, not to ignorance of a gross character, but to a difference of opinion as to where abrasion or erosion stops and ulceration commences.

Close of the Session.—The hour for adjournment having arrived, several papers were read by title only. Dr. Sims then introduced his successor, the President elect, Dr. Byford, of Chicago, after which the society adjourned, to meet in New York on the third Wednesday in September, 1881.

—

Change in School Terms.—The College of Physicians and Surgeons and Bellevue Hospital Medical College, in response to the unmistakable demand for improvement in the curriculum, have lengthened their winter course, so that, at the former school, it begins on the 1st of October and ends about the last of April, and at Bellevue it began September 15th, and will end about the middle of March. The preliminary fall course in both schools is now abolished.

—

The Sanitary Protection Association of Newport, R. I.—This Society was founded in 1878, after the model of the Edinburgh Association established by Mr. Jenkin, and has for its objects (1) to provide its members, at moderate cost, with such advice and supervision as shall insure the proper sanitary condition of their own dwellings; (2) to enable members to procure practical advice, on moderate terms, as to the best means of remedying defects in houses of the poorer class in which they are interested; and (3) to aid in improving the sanitary condition of the city. The Association has just completed its second year, and is steadily increasing its good work and gaining ground in public estimation. During the past twelvemonth eighteen inspections were made, and in all, with but a single exception, very grave defects were discovered. The sum of one hundred dollars has been placed at the disposal of the Association, for the purpose of awarding prizes to the owners of dwellings, who shall, for the space of one year, keep their premises in the most perfect order and sanitary condition. Dr. H. R. Storer is the Corresponding Secretary, and Colonel George E. Waring, Jr., the Consulting Engineer of the Society.

—

British Medical Association.—The forty-eighth annual meeting of the British Medical Association was held at Cambridge, August 10, 11, 12, and 13, under the Presidency of Prof. Humphrey. The Address in Medicine was delivered by Dr. Bradbury, that in Surgery by Mr. Timothy Holmes, and that in Physiology by Dr. Michael Foster. There were about eight hundred members present, and the meeting was considered in all respects a brilliant success. The subject of holding the annual meeting in 1881, was remitted to the consideration of the Council in consequence of the proposed International Medical Congress in August of next year.

At the annual dinner of the Association the President proposed the toast of "Our Guests" and dwelt upon the kindly relations existing between the profession of Great Britain and the profession on the Continent and in America, and coupled the toast with the names of Prof. Brown-Séquard and Prof. Gross. Prof. Gross in appropriate words responded to the toast. He warmly urged the cultivation of social intercourse between the two great nations represented by the association and by himself; and he assured his hearers of the sympathy of the profession in America.

—

Honorary Degrees Conferred at Cambridge.—In accordance with the announcement, the honorary degree of Doctor of Laws was conferred on the 11th of August, by the University of Cambridge, upon Dr. C. E. Brown-Séquard, of Paris; Dr. Donders, of Utrecht; Dr. S. D. Gross, of Philadelphia; Sir Wm. Jenner, Bart., Sir Wm. Gull, Bart., Sir George Burrows, Bart., Mr. Wm. Bowman, the Rev. S. Haughton, M.D., Mr. Joseph Lister, Dr. D. C. O'Connor, Mr. J. Simon, and Dr. Andrew Wood.

The Public Orator, Mr. Sandys, introduced each candidate to the Vice-Chancellor in a short Latin speech. Dr. Gross was introduced as follows:—

"Trans fluctus Atlanticos, trans Oceanum non iam ut antea 'dissociabilem;' patriæ nostræ ad portus nuper advectus est vir venerabilis quem inter fratres nostros Transatlanticos scientiæ Chirurgicæ quasi alterum Nestorem nominare ausim. Ergo libenter quasi fraterno amore hodie salutamus, civitatis bene ominati nominis civem, Chirurgiæ Professorem Philadelphiensem, Samuelem Gross."

The *Lancet*, in commenting on the honors of Cambridge says: "Brown-Séquard, Gross, and Donders could not be more gratified with the rare honour of receiving the honorary degree of LL.D. Cantabriensis, than the profession of Britain will be gratified to know that they have received it."

—

International Medical Congress, London, 1881.—From the official circular of the Congress, just received, we learn, in addition to the announcement already made (see *Medical News* for September, page 572), that the days of the meeting will extend from Wednesday the 3d, to Tuesday the 9th of August, both days included, and that a Reception of Welcome will take place on the evening of August 2.

The Executive Committee inform their "colleagues abroad that ladies will be invited to the social and ceremonial meetings of the Congress, but will not be admitted to its business meetings."

Dr. Risdon Bennett, President of the Royal College of Physicians of London, has been appointed Chairman of the Executive Committee, and Mr. Prescott Hewitt, Chairman of the Reception Committee.

—

International Sanitary Conference.—The President has issued a call for an International Sanitary Conference to meet at Washington, D. C., on the first day of January, 1881, to which the several powers having jurisdiction of ports likely to be infected with yellow fever or cholera, have been invited to send delegates, properly authorized, "for the purpose of securing the adoption by the powers in question of an international system of notification as to the actual sanitary condition of ports and places under the jurisdiction of such powers, and of vessels sailing therefrom.

The specific propositions which will be submitted to the conference will include the following:—

A. The establishment of a reliable and satisfactory international system of notification as to the existence of contagious and infectious diseases, more especially cholera and yellow fever.

B. The establishment of a uniform and satisfactory system of bills of health, the statements in which shall be trustworthy as to the sanitary condition of the port of departure and as to the condition of the vessel at the time of sailing.

The discussion of these points would involve, among others, the following questions:—

I. Who should be the certifying officer or authority as to the sanitary condition of ports and places and of vessels?

II. How can the certifying authority obtain trustworthy information as to the actual sanitary condition of ports and places and as to the presence of contagious and infectious diseases?

III. When yellow fever or cholera exists at or in the vicinity of a port or place, what examination should be made of a vessel sailing therefrom to secure a trustworthy knowledge of her sanitary condition?

IV. To what extent, and under what conditions, should a clean bill of health be considered as affording satisfactory evidence that the vessel is free from danger of conveying infectious disease?

V. In what way can trustworthy information be obtained from ports or places in countries which have imperfect or unsafe quarantine and sanitary regulations, and which may be unwilling or unable to adhere to the proposed international system?

VI. Whether a schedule of graduated penalties could be fixed to be exacted from vessels for various offences arising under the proposed international system.

—

Meeting of the Medical Society of Virginia.—This Society will meet in Danville on October 19th, at half-past seven P. M.

—

Kentucky State Medical Society's Transactions.—At the last meeting of this Society, it was resolved to discontinue the publication of a volume of Transactions, simply publishing the minutes in pamphlet form. The papers read before the Society may be published by their authors in any regular medical journal. It is proposed to appropriate the money heretofore spent in publishing the Transactions towards the creation of a prize essay fund.

The Case of the late Miss Adelaide Neilson.—As the reports which have reached this country of the sudden illness and death of this distinguished *artiste* seemed to envelop the case in considerable mystery the following account of her illness and death, which appears in the *Lancet* (Aug. 28th), by Dr. W. E. JOHNSTON, of Paris, who has been her physician for the last five years, will be read with melancholy interest by her many admirers on this side of the Atlantic.

Dr. Johnston says "the disease from which she suffered principally was gastralgia—one of the forms of dyspepsia attended with neuralgia of the stomach, a form extremely fantastic in its coming and going, and in her case quite as dependent on moral causes as on errors of diet. The last fatal attack in the Bois de Boulogne was evidently one of her usual attacks of gastralgia, which might have been relieved then, as it often had been before, by a free use of morphine. The unfortunate lady sent her maid for me at seven o'clock, but to my great regret I was absent that evening on a visit to my family in the country, and did not hear of her illness till I heard of her death. At three o'clock in the morning, twelve hours from the commencement of the attack, during a most violent recurrence of the pain, she suddenly ceased to complain, went into a state of syncope, and died in the syncope. The post-mortem examination made the next day by Dr. Brouardel, Professor of Legal Medicine at the Medical School of Paris, and now one of the first authorities in Europe in legal medicine, disclosed the extraordinary fact, one of the rarest in the history of medicine, that in her writhing she had ruptured a varicose vein in the left Fallopian tube, and had died from internal hemorrhage. Two quarts and a half of blood were found in the peritoneal cavity, and the ruptured vein presented an orifice of from four to five millimetres in diameter."

Literary Notes.—The Government Printing Office has just issued the first volume of the Index Catalogue of the Library of the Surgeon-General's Office. The attention of the readers of the *News* has been, from time to time, called to the magnitude of this work, which is practically an author and subject index of medical literature to date of publication. The first of the projected ten volumes contains 888 quarto pages, extends from A to Berlinski, and justifies the high anticipations that have been formed of its value. The work has been compiled under the supervision of Surgeon John S. Billings, to whose intelligent zeal and indomitable energy the Government is indebted for this noble contribution which it has made to the cause of medical science and of the healing art.

The September number of the *Popular Science Monthly* contains an interesting biographical sketch, with portrait, of Dr. Joseph Leidy, of the University of Pennsylvania, which will be read with the interest which always attaches to the history of one whose scientific labours have rendered his name known wherever natural history is cultivated.

OBITUARY RECORD.—Died, at Vienna, on the 5th of August, aged 64, FERDINAND R. V. HEBRA.

Prof. Hebra was born at Brünn in 1816, and pursued his medical studies at Vienna where he graduated in 1841. He then became assistant to Skoda, and was induced by his illustrious teacher to devote himself to the study of dermatology. In 1842 he delivered his first private course of lectures. Shortly afterward, through the influence of Skoda, a section in the hospital was founded for skin diseases, at the head of which Hebra was placed. In 1848 Hebra was made Extraordinary Professor and his lectures were largely attended by students from all parts of the world. His scientific labours were numerous, the principal of them are thus described by Prof. Neumann, "although the existence of the itch mite was made known centuries ago, yet few practitioners were in a position to find and demontrate it prior to 1844, when Hebra exhibited the galleries formed by it in the penis, the buttocks, the umbilicus, and the bend of the elbow, explaining at the same time that the efflorescence produced was of a traumatic nature. Heretofore the view had prevailed that the papules, vesicles, and pustules were due to a diseased condition of the blood. Taught by his abundant experience, Hebra opposed the employment of stimulant substances to the skin, having arrived at the conviction that the relief they afforded was only temporary, while in scrofulous or cachectic subjects sometimes great mischief to the skin followed their use. The expectant treatment, which Hebra had studied under his teacher Skoda, he carried into the practice of skin diseases, and as a consequence of this principle the great bulk of the stores of medicinal applications were banished forever. In the treatment and etiological foundation of eczema, Hebra took a most prominent part, fixing its diagnosis upon new points of view, and establishing its treatment on a more certain basis. He proved the impossibility of the retrocession of diseases of the skin, and showed that the symptoms from which the idea of retrocession had arisen—the disappearance of the eruption on the occurrence of typhus or pneumonia, the paling of erysipelas, erythema, or scarlatina during the agony of death, and the absence of redness in the corpse—was really the result of anæmia of the skin. Hebra employed a classification of skin diseases, which, already designed by Rokitansky in its essential features, was found well adapted to clinical requirements. In 1842 he first re-introduced the banished mercurial treatment; not that he ever became an excessive mercurialist, his principle being to try again all remedies without prejudice. He employed as well the various other anti-syphilitic means, iodine, non-specific treatment, syphilization and vaccination of the syphilitic."

During ten years, Hebra edited the *Zeitschrift der Gesselschaft der Aerzte in Wein*, and in this he published several papers, as, for example, on the most important Diseases of the Hairy Scalp, his Classification of Skin Diseases, on Herpes Tonsurans and Norwegian Scabies, etc. Among his great works are his magnificent "Atlas der Hautkrankheiten," published by the Vienna Academy of Sciences, and his "Handbuch der specielle Pathologie und Therapie der Hautkrankheiten," translated by the New Sydenham Society.

Prof. Hebra's fame was recognized throughout the civilized world, and by his death the Vienna Medical School has sustained its greatest loss since the retirement of Rokitansky.

—— At Somerville, Mass., on August 29th, Charles Thomas Jackson, M.D., aged 75 years.

Dr. Jackson was born at Plymouth, June 21, 1805; he studied under Drs. James Jackson and Walter Channing, and graduated in medicine at Harvard University in 1829. After a course of study abroad, he settled in Boston in 1833, and devoted much of his time to chemistry, mineralogy, and geology. He is best known to the medical profession as the claimant to the discovery of surgical anæsthesia, and he received from the French Academy of Sciences the Monthyon prize of 2500 francs for the discovery of etherization.

—

To Readers and Correspondents.—The editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

MEDICAL AND SURGICAL TEXT-BOOKS.

DISEASES OF WOMEN AND CHILDREN.

THOMAS'S PRACTICAL TREATISE ON THE DISEASES OF WOMEN. New edition. In one octavo volume of over 850 pages, with about 270 illustrations. (*In press.*)

EMMET'S PRINCIPLES AND PRACTICE OF GYNÆCOLOGY. In one octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, $6.50.

BARNES ON WOMEN. In one 8vo. volume of 784 pages, with 181 illustrations. Cloth, $4.50; leather, $5.50; half Russia, $6.

WEST'S LECTURES ON THE DISEASES OF WOMEN. In one 8vo. volume of about 550 pages. Cloth, $3.75; leather, $4.75.

SMITH'S COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. In one octavo volume of 750 pages, with illustrations. Cloth, $4.50; leather, $5.50; half Russia, $6.

WEST'S LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD. In one 8vo. volume of 678 pages. Cloth, $4.50; leather, $5.50.

MIDWIFERY.

LEISHMAN'S SYSTEM OF MIDWIFERY. In one octavo volume of 733 pages, with over 200 illustrations. Cloth, $4.50; leather, $5.50; half Russia, $6.

PLAYFAIR'S TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY. In one 8vo. volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5.50.

RAMSBOTHAM'S OBSTETRICS. In one imperial 8vo. volume of 650 pages; many plates and illustrations. Leather, $7.

WINCKEL'S COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED. In one octavo volume of 484 pages. Cloth, $4.

HODGES'S PRINCIPLES AND PRACTICE OF OBSTETRICS. In one large quarto volume of 550 double-columned pages, with many lithographic plates and engravings. Cloth, $14.

BARNES'S MANUAL OF MIDWIFERY. In one 12mo. volume of 200 pages, with 50 illustrations. Cloth, $1.25.

SURGERY.

GROSS'S SYSTEM OF SURGERY. In two imperial 8vo. volumes of 2268 pages, with 1400 illus. Leather, $15; half Russia, $16.

ASHHURST'S PRINCIPLES AND PRACTICE OF SURGERY. In one 8vo. volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7.50.

BRYANT'S PRACTICE OF SURGERY. In one imperial 8vo. volume of over 1000 pages, with 672 illustrations. Cloth, $6; leather, $7; half Russia, $7.50.

ERICHSEN'S SCIENCE AND ART OF SURGERY. In two 8vo. volumes of nearly 2000 pages, with 862 illustrations. Cloth, $8.50; leather, $10.50; half Russia, $11.50.

HOLMES'S SURGERY. In one 8vo. volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, $7.50.

STIMSON'S MANUAL OF OPERATIVE SURGERY. In one 12mo. volume of 477 pages, with 332 illustrations. Cloth, $2.50.

DRUITT'S PRINCIPLES AND PRACTICE OF MODERN SURGERY. In one 8vo. volume of nearly 700 pages, with 432 illustrations. Cloth, $4; leather, $5.

HAMILTON'S TREATISE ON FRACTURES AND DISLOCATIONS. In one octavo volume of over 900 pages, with 352 illustrations. Cloth, $5.50; leather, $6.50; half Russia, $7.

GROSS'S PRACTICAL TREATISE ON DISEASES AND INJURIES OF THE URINARY ORGANS. In one 8vo. volume of 574 pages, with 170 illustrations. Cloth, $4.50.

THOMPSON ON DISEASES OF THE URINARY ORGANS. In one neat octavo volume, with illustrations. Cloth, $2.25.

DISEASES OF THE EYE AND EAR.

WELLS ON DISEASES OF THE EYE. In one 8vo. volume of 900 pages, with 250 engravings and six colored plates. Cloth, $5; leather, $6; half Russia, $6.50.

NETTLESHIP ON THE EYE. In one 12mo. vol. of 369 pages, with 89 illustrations. Cloth, $2.

CARTER ON DISEASES OF THE EYE. In one 8vo. volume of 500 pages, with 124 illustrations. Cloth, $3.75.

BURNETT ON THE EAR. In one 8vo. volume of 615 pages, with 87 illustrations. Cloth, $4.50; leather, $5.50; half Russia, $6.

MEDICAL JURISPRUDENCE.

TAYLOR'S MEDICAL JURISPRUDENCE. In one 8vo. volume of nearly 900 pages. (*In press.*)
TAYLOR ON POISONS. In one 8vo. volume of 850 pages. Cloth, $5.50; leather, $6.50.

MANUALS.

DUNGLISON'S MEDICAL LEXICON. In one 8vo. volume of 1131 pages. Cloth, $6.50; leather, $7.50; half Russia, $8.

HOBLYN'S MEDICAL DICTIONARY. In one 12mo. volume of over 500 pages. Cloth, $1.50; leather, $2.

HARTSHORNE'S CONSPECTUS OF THE MEDICAL SCIENCES. In one 12mo. volume of over 1000 pages, with 477 illustrations. Cloth, $4.25; leather, $5.

LUDLOW'S MANUAL. In one 12mo. volume of 816 pages, with 370 illustrations. Cloth, $3.25; leather, $3.75.

NEILL AND SMITH'S ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE. In one 12mo volume of about 1000 pages, with 374 illustrations. Cloth, $4; leather, $4.75.

(*See second page of cover.*)

HENRY C. LEA'S SON & CO., Philadelphia.

NOTICE TO SUBSCRIBERS.

INCREASED INDUCEMENTS FOR 1880.

With a view of increasing the attractions of the "American Journal of the Medical Sciences," and of bringing within the reach of all members of the profession the immense amount of information now presented by it and its accessory periodicals, the "Medical News and Library" and the "Monthly Abstract," the two latter will hereafter be merged together, under the name of "The Medical News and Abstract," commencing January 1, 1880. The "News and Abstract" will consist of sixty-four pages per month, handsomely printed, in a neat cover, and will contain all the material heretofore presented in both periodicals, with the exception of the sixteen pages of the "Library Department." Its price will be Two Dollars and a Half per annum, invariably in advance, at which rate subscribers will receive nearly *eight hundred large octavo pages per annum*, free of postage.

Not only will this monthly thus be in itself one of the cheapest periodicals offered to the profession, but it will be furnished in commutation, without charge, to advance-paying subscribers of the "American Journal of the Medical Sciences," the subscription to which will remain, as heretofore, Five Dollars per annum. For this very moderate sum, therefore, subscribers will receive two periodicals of the highest class, a Quarterly and a Monthly, containing in all nearly two thousand pages per annum, stored with the choicest original and selected matter that can be furnished by the medical literature of both hemispheres.

These terms may be recapitulated as follows:—

TERMS FOR 1880.

The American Journal of the Medical Sciences, published quarterly (1150 pages per annum), and The Medical News and Abstract, published monthly (768 pages per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The American Journal of the Medical Sciences, when not paid for in advance,	Five Dollars.

The Medical News and Abstract, invariably in advance, Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the Journal (two annually) and the News and Abstract (one annually), free by mail, on remitting ten cents for each cover.

It is evident that only a very considerable increase to the existing subscription list will justify the unexampled terms thus offered, by which the equivalent of three or four large octavo volumes is furnished, handsomely printed in a form for preservation, for the trifling sum of Five Dollars. Gentlemen, therefore, are respectfully requested to lose no time in remitting their subscriptions, to avoid the risk of disappointment from the exhaustion of the edition printed; and it is suggested that they may aid in rendering the enterprise permanent by kindly communicating to their friends the very great inducements thus offered.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "Journal" and "News and Abstract" may be made at the risk of the publishers by forwarding in registered letters. Address

HENRY C. LEA'S SON & CO.,
Nos. 706 and 708 SANSOM STREET,
PHILADELPHIA, PA.

THE

MEDICAL NEWS

AND

ABSTRACT.

A CONSOLIDATION OF THE "MEDICAL NEWS AND LIBRARY" AND
THE "MONTHLY ABSTRACT OF MEDICAL SCIENCE."

EDITED BY

I. MINIS HAYS, A.M., M.D.

PHILADELPHIA:
HENRY C. LEA'S SON & CO
1880.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

tered according to the Act of Congress, in the year 1880, by HENRY C. LEA'S SON & Co., in the Offic
of the Librarian of Congress. All rights reserved.

NEW MEDICAL BOOKS.

THOMAS ON WOMEN—New and Revised Edition—Just Ready.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. GAILLARD THOMAS, M.D., Professor of Obstetrics in the College of Physicians and Surgeons, New York. Fifth edition, thoroughly revised and rewritten. In one large and handsome 8vo volume of over 800 pages, with about 270 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50.

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions, a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

FLINT'S PRACTICE—New Edition—In Press.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE, designed for the Use of Students and Practitioners of Medicine. By AUSTIN FLINT, M.D., Professor of the Principles and Practice of Medicine and of Clinical Medicine in Bellevue Med. College, N. Y. Fifth edition, thoroughly revised and much improved. In one large and closely-printed octavo volume of about 1100 pages.

EXTRACT FROM THE AUTHOR'S PREFACE TO THE FIFTH EDITION.

In preparing the fifth edition of this treatise, the author has been thoroughly mindful of the progress of medicine since the publication of the fourth edition, in 1873. Time and labor have not been spared in the endeavor to bring the work, in all respects, up to the present state of medical knowledge.

Dr. William H. Welch, lecturer on Pathological Histology in the Bellevue Hospital Medical College, has contributed in Part I. the first seven chapters, embracing the general pathology of the solid tissues and of the blood. He has also revised, and in great part rewritten, the descriptions of the anatomical characters of the diseases considered in the rest of the volume. It is believed that these portions of the work will serve as a digest of the essential facts pertaining to general and special pathological anatomy, as far as this important branch of study bears upon practical medicine.

In the other portions of the treatise many changes will be found, which have somewhat enlarged the size of the volume, in spite of the omission of a considerable amount of matter, and the rewriting of many portions with a special view to condensation. Among these changes may be mentioned numerous improvements in the arrangement, including the classification of the diseases of the nervous system on an anatomical, in place of a symptomatic basis, and the consideration of various diseases not embraced in previous editions. In short, the eliminations, substitutions, and additions, render the present edition virtually a new work.

In making changes, the author has not been influenced by any sense of obligation to maintain consistency of views with the previous editions of this treatise, or with other works which he has written. If statements be found to vary from those made at a prior date, the simple explanation is that the latter, in the light of more recent reflection and enlarged knowledge, seem to him no longer tenable. He has endeavored to regard his own past writings in this point of view, divested of the partiality of authorship, and to subject them to as critical an examination as if they were the writings of another.

TAYLOR'S MEDICAL JURISPRUDENCE—New Edition—Nearly Ready.

A MANUAL OF MEDICAL JURISPRUDENCE. By ALFRED S. TAYLOR, M.D., late Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital, London. Eighth American edition. Edited by JOHN J. REESE, M.D., Professor of Medical Jurisprudence and Toxicology in the Univ. of Pa. In one large and handsome 8vo. vol. of about 850 pages.

BRYANT'S SURGERY—New Edition—In Press.

THE PRACTICE OF SURGERY. By THOMAS BRYANT, F.R.C.S., Surgeon to Guy's Hospital. Third American, from the second and revised English edition. Thoroughly revised and much improved, by JOHN B. ROBERTS, M.D. In one large and very handsome imperial octavo volume of over 1050 pages, with 672 illustrations.

CLINICS.

Clinical Lectures.

ON CIRRHOSIS OF THE LIVER.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE GOOD SAMARITAN, CINCINNATI.

BY JAMES T. WHITTAKER, M.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE, MEDICAL COLLEGE OF OHIO.

GENTLEMEN: We have, to-day, to discuss a disease without a parasite. We have had much to say hitherto about germs and parasites in connection with all cases of acute infectious disease. We have seen acute articular rheumatism, forms of Bright's disease, tuberculosis, and even that "type of acute inflammations," lobar pneumonia, fall into the line of the acute infections, so that now it would seem almost pertinent to ask: Is there any disease which is not due to the all-prevailing parasite?

Two centuries ago, it was scurvy which was the *fons et origo mali.* According to Eugalenus it was omnipresent. All children are born with it, Drawitz said; all diseases are complicated with it, said Mœllenbroeck or are produced by it, said Bonteroe. A century later, Hahnemann pronounced the psora, the itch, as the cause of every kind of chronic disease. Ours is the day of the parasite. I speak of it, however, in no spirit of levity. For the acquisitions of our day are not conceptions merely, not revelations of inspiration. They are discoveries of investigation, objective, and not subjective disclosures. Nevertheless, it is refreshing to have to study a disease with the pathogeny of which parasites or germs have nothing at all to do.

Our patient, as the history just read informs us, is a man of 42, a German by birth, and a brewer by occupation. He has been in the habit of drinking beer very freely every day, and not content with this, he has taken "schnapps" every morning besides. This has been his habit for years. About six months ago he began to feel dyspeptic. He had heartburn, pyrosis, occasional nausea, and gastric distress. He was constipated for the most part, but had now and then attacks of diarrhœa. For the relief of all these troubles, he always took "schnapps." Pretty soon he began to vomit, and now he vomits every day, just before breakfast, he says. Bacchus, as well as Neptune and Venus (or Lucina), demand matutinal offerings. He has had hæmorrhoids several times, but they have never bled, and are now not present at all. He does not remember to have ever had any kind of dropsy. He has lost in his illness, he says, forty pounds of flesh. Let us look at him as he shows himself to-day.

He is a man of large, powerful frame, but he is evidently reduced in weight and strength. He seems listless and dejected. His skin has a sallow hue and is dry and scaly. The conjunctivæ are as yellow as in common jaundice. So far as we can see, there is nothing wrong in the brain, the lungs, or the heart. The fault lies below the diaphragm. The liver is evidently reduced in size. You catch the tympanitic sound of the distended colon well up under the ribs, where we should have hepatic dullness. I cannot feel the edge of the liver under the ribs even when following it up on forced expiration. At the same time the pulmonic resonance is clear down to and below the nipple. In other words, the liver is not pushed up from below, it is simply reduced in size. But the spleen is very large. It is palpable below the ribs, and percussion shows horizontal dulness from the sternum to the spinal column. To discover this anomaly, we have the patient lie upon his right side, with the left arm extended above his head. For the spleen enlarges sideways first, as much as it may, before it extends below the ribs. If you will remember this fact you may some day confirm in this way a suspicion of a walking case of typhoid fever, in which, as in all infectious diseases, the spleen becomes enlarged. The surface veins of the abdomen, which we should be barely able to see, make a visible network here. And now, as I have him stand, I catch by tapping upon the surface, sufficiently distinctly for recognition, the touch of a fluctuating fluid within. In this position the line of the fluid reaches up nearly half way to the umbilicus.

Clearly, we have before us a case of cirrhosis in the stage of commencing, or fully commenced, retraction. We have, therefore, to speak of this disease as illustrated in the case before us.

The liver is such a big and prominent organ, and was the supposed seat of so many functions, even sensations, as to have received much attention from the earliest times. The very gross lesions of advanced cirrhosis could not escape the keen observation of the old pathologists, or rather anatomists, for pathology, in our understanding of it, is a modern field, and so we find allusion to it by even the writers of antiquity. What especially attracted their attention was the change in its consistence. Thus, Aretæus speaks of the *hepar durum*, and *hepar scirrhus* was another appellation to indicate hepatic induration. Bianchi even spoke of the "*jecus in minimam molem retractum*," and Vesalius of a case, attended with the well known symptoms in life, where the liver, on autopsy, was found "*totum candidum et multis trabeculis asperum*," etc.

Morgagni reported from his own observation, and from that of others, undoubted cases of cirrhosis in which the liver was found after death "*totum granulosum.*"

This was, however, the sum and substance of our knowledge of cirrhosis up to the time of Laennec (1819). The disease was not yet known as an affection distinct from others, from cancer, for instance, and nothing was known at all, as yet, either of amyloid or syphilitic change, or of the change produced by organic disease of the heart. So all these affections were confounded with cirrhosis.

Laennec came upon the disease quite accidentally in the course of his examinations of disease of the lungs. He had under observation a fatal case of pleurisy with hemorrhage from the lungs, and he noticed at the autopsy the curious condition of the liver, which he describes in a few words. As this was the first recognition of the disease as a separate affection the description is worthy of mention. He found the liver, he says, "reduced to one-third of its volume, concealed in the place it occupies, and seemingly composed of a multitude of grains of millet seed of a yellow or yellowish-red colour." In a foot-note he adds: "This is a species of production which has been called scirrhus. I will designate it cirrhosis, because of its colour [χιῤῥός, tawny, or orange-colour]. Its development in the liver is one of the most common causes of ascites. The liver is always atrophied when it contains these cirrhoses." Laennec, therefore, regarded the "cirrhoses" as new formations, and, in accord with this view, Abercrombie described the yellow matter of cirrhosis as "in small nodules like peas dispersed through the substance of the liver." It is amusing, in the light we now possess of the nature of cirrhosis, to read in Abercrombie that the "French writers have a controversy whether the cirrhosis or yellow degeneration of the liver be a new formation, or a hypertrophia of the yellow substance which they suppose to constitute a part of the structure of the liver in its healthy state. No good can arise from such discussions," he näively adds, "as it is impossible to decide them."

But we must not spend too much time with the history of the disease. It will be sufficient now to say that in the same year of the recognition of this the common form of cirrhosis (Laennec's cirrhosis, the French still call it), Bouillaud showed that the nodular or granular appearance was due to atrophy of the red substance of the liver, whence resulted a more salient projection of the yellow substance. Kiernan (1836) first clearly pointed out the hyperplasia of the interstitial connective tissue which we now know to be the lesion of cirrhosis, and Gubler (1853) first called attention to the fact that the first stage of the disease is characterized by hypertrophy, the second by atrophy of the liver. Finally, Klebs (1868) first proclaimed phlebitis and periphlebitis of the radicles of the portal vein as the initial anatomical factor in the pathology of the disease. It is not the granules, therefore, which constitute the disease. The granules represent constrictions of the liver substance. The constricting agents, the connective tissue, constitute the disease, which is properly designated, as Bamberger has shown, "chronic interstitial hepatitis."

Almost from the very first recognition of the disease the cause of it was known. By all writers and clinicians cirrhosis is looked upon as an expression of chronic alcoholism. "Gin-drinker's" liver is its common name in England, and the extent of the use of alcohol determines the geography of the disease. Males are its most frequent victims, because, as Hyrtl has remarked, "drinking is one of the manly accomplishments." But typical cases are encountered among females, under the same conditions. Even the apparent exceptions, Niemeyer says, support the rule. "Thus Wunderlich found typical cases of the disease in two sisters, aged eleven and twelve years; but, on careful inquiry, it was found that both of them were great schnapps-drinkers."

The liver has singular affinity, so to speak, for alcohol in any form. Percy found that he could recover alcohol in the bodies of dogs poisoned with it, from the blood, the brain, and other organs, but in greatest quantity from the liver. The researches of Perrin, Lallemand, and Duroy have shown that if we represent by 1 the quantity of alcohol found in the blood, after the ingestion of a certain amount of it, that found in the brain will be represented by 1.34, and that in the liver by 1.38. This accumulation of alcohol in the liver, taken in connection with the sluggishness of the circulation in the liver, the hepatic radicles being the second set of capillaries, furnish sufficient explanation of the selection of the liver as the organ which shall suffer most from the toxic effects of alcohol. Inasmuch, however, as all drinkers do not suffer alike, we must invoke, in addition to the alcoholism, some special susceptibility which renders the individual liable to the disease. In this respect cirrhosis does not differ from nearly all affections. The continuous reception and escape of alcohol in the organs of secretion finally induce in them, at first irritative, and then inflammatory change. First in order is chronic catarrh of the digestive tract, then degenerations of the glandular organs, atheroma of the vessels, pachymeningitis, forms of Bright's disease, and, what concerns us now, cirrhosis of the liver. Thus, epithelial cells and lining cells of vessels perish under long-continued application of alcohol, but the connective tissues, before they perish, are stimulated, under irritation, to excessive growth. Like rank weeds, under fertilization, the connective tissue swells and spreads exuberantly. Alcohol reaches the liver through the radicles of the portal vein. These radicles, at their ultimate termination, are among the finest and thinnest, as well as among the richest systems of vessels in the body. The unoxydized alcohol, that is that which is in excess of consumption, passes by easy osmosis through their delicate walls and bathes the equally delicate fibres and threads of connective tissue which form the soft skeleton work of the recesses of the liver. The nuclei multiply, the threads become cords and bands, the whole liver swells. This is the first or hypertrophic stage of cirrhosis of the liver. When the connective tissue has attained its full maturity, it begins to shrink. The connective tissue in the liver contracts just as scar tissue shrinks everywhere else—on the face, for instance, and the deformity of the liver that results is just as great. For the liver is so shrunken up by the retractile threads of connective tissue as to look, both upon its free surface, and upon the surface of section everywhere, like the bottom of an iron-founder's shoe. "Hob-nail liver," it is sometimes called, and the hobs or nodules may be sometimes felt in thin people, or after tapping, even beneath the skin. It is not unfrequent to find the whole of the left lobe shrivelled to a mere appendage to the right.

Wickham Legg maintains that the primal factor in cirrhosis is constriction of the bile-ducts. He has shown, he claims, that obliteration of the ducts always leads to an overgrowth of the connective tissue in the liver in children, and that a no less marked cirrhosis ensues upon ligature of the ducts in the lower animals. Now it would be a very simple sequence to ascribe cirrhosis first to a catarrh of the duodenum which would so thicken the orifice of the common bile-duct as to interfere with excretion, and thus induce as secondary factors retention of bile, and, in consequence of its irritation, cirrhosis of the liver. The sequence is so simple as to be seductive. But the facts as they occur speak against it. For, in the first place, true jaundice is rare in cirrhosis, and it should be most pronounced in cases of occlusion, and, in the second place, the same cirrhotic change, that is, the same proliferation of connective tissue, attends chronic alcoholism in organs when there is no bile, as in the kidneys and the brain. The real sequence of pathogeny and pathology is this: alcoholism, periphlebitic hyperplasia, cirrhosis in the second stage.

The symptoms of cirrhosis irradiate from the liver as the central point. Most of them are easy of explanation on mere mechanical grounds. A few of the last and worst of them call out a knowledge of the physiology of the liver.

We never know just when the cirrhotic process begins in the liver, for the first symptoms are purely gastric. Gastric catarrh with its well-known attendants precedes the more pronounced and peculiar phenomena of the disease, for months, or even years. Our patient describes, in the course of his own case, the vanguard of the symptoms of the disease. Gastric distress, nausea, and vomiting, especially in the morning, heartburn, constipation alternating with diarrhœa; this is the train of symptoms that march in the front, or by the side of cirrhosis of the liver, for months and years, at times, before the symptoms of more complete obstruction arrive. Gradually, however, the hyperplasia of the connective tissue advances, or gradually it tightens up in its contraction upon the intervening liver-cells and vessels and ducts. The skin grows sallow and dry, the conjunctivæ are yellow from the start, emaciation sets in, all from lack of formation, or from slight reabsorption of blocked-up bile, then water is forced out of the radicles of the portal vein into the abdominal cavity, and from these distended vessels blood may escape into the stomach or intestine. Collateral circulation may, to some extent, compensate for the occlusion of the portal vein, and thus obviate for a time the worst phases of the mechanical hindrance. In fact, it is the establishment of collateral circulation that chiefly protracts the life of the individual affected with the disease. It is a matter of real surprise how many avenues of collateral circulation are brought into play in atrophy of the liver. There are vessels in the gastro-hepatic omentum from the lesser curvature of the stomach and connective tissue between the folds of the omentum, there are 12 to 15 small vessels which pass from the gall-bladder; besides these, the vasa vasorum, the vessels which run along the walls of the portal vein, hepatic artery, and bile-ducts; a fourth group descend from the diaphragm in the suspensory ligament; a fifth, the largest of all, the vessels which form the visible network on the surface of the abdomen, communicating with the epigastric and internal mammary veins; a sixth, the vessels which ramify upon the œsophagus and empty into the diaphragmatic veins. Fatal hemorrhage has been reported by Audibert, and Fauvel, from œsophageal varices formed in this way. Rokitansky first called attention to the circle of tortuous and distended vessels about the umbilicus, representing the so-called "caput Medusæ," not present in our case, and present in cases of cirrhosis, rather as an exception than a rule. After much discussion concerning these vessels, I believe the appearance is now admitted to be due to the reopened umbilical vein (Bamberger, Baumgartner, and Klebs). These various avenues of collateral circulation may become enlarged to such a degree as to relieve the pressure in the portal vein, and thus allow to disappear the ascites already formed, or, if preternaturally of large size, to prevent its appearance altogether. It is only in this way that we may account for the fact that a certain percentage of cases, according to Frerichs, one-third of the whole number, show no ascites at all.

Digestive disturbance, partly the direct effect of alcohol, partly the effect of arrest of the hepatic function, emaciation, and corresponding reduction of strength from the same cause, ascites, enlargement of the spleen, hemorrhoids, and hemorrhages from mechanical occlusions, enlargement, and subsequent contraction of the liver itself; these are the chief and prominent symptoms of the disease. It remains now to take a cursory glance at the symptoms of secondary import.

Jaundice is seldom marked. Some slight discoloration of the skin belongs to every case, but genuine icterus betokens rather an accidental complication (gall-stone, compression by a band of hyperplastic tissue, catarrh of the bile-ducts, etc.). Icterus is exceptional in cirrhosis for the simple reason that the destruction of the liver-cells prevents the formation of bile.

General dropsy or œdema of the lower extremities does not belong to the symptomatology of cirrhosis. A great accumulation of ascites may compress the vena cava, or a profound debility, the general result of the suppression or annihilation of the function of the liver, may cause general dropsy, but these factors are not peculiar to cirrhosis. So accumulations of fluid in the abdomen, or the heavy weight of the liver may interfere with the action of the diaphragm, and thus induce dyspnœa; but symptoms on the part of the respiratory system do not constitute an integral part of the history of the disease.

The brain is clear in cirrhosis throughout the course of the disease, but towards its close, when the atrophy of the liver-cells has become more or less complete, there supervene, at times, grave symptoms on the part of the nervous system, delirium, convulsions, or coma, which indicate the toxic effects of elements that should be excreted with the bile. Pain or even tenderness is quite exceptional, and is due, when present, to perihepatitis. The shoulder-tip pain, which may be present in cirrhosis, as well as in every other organic disease of the liver, is satisfactorily explained by the anatomical demonstration by Luschka of the anastomosis of the phrenic and fourth cervical nerves.

The urine in cirrhosis furnishes most valuable evidence. It is scanty, dark, and turbid, loaded with urates and other products of combustion, the result of the wide-spread havoc in nutrition. A clear and limpid urine would speak strongly against the existence of the cirrhotic process. It is now well known that the liver is the chief organ in the body in the manufacture of urea, but it is not necessary to appeal to this fact, when the waste is so universal, to account, in cirrhosis, for the accumulation of the urates (undecomposed urea) in the urine.

Lépine has lately called attention to the glycogenic function of the liver in connection with cirrhosis. The liver makes and uses up sugar in greater abundance than any other organ in the body. Lépine found that sugar appeared in the urine of cirrhotic patients who had been fed with it, a result that might have been inferred from the destruction of the liver cells. In cancer this is not the case, because cancer is mostly localized in the liver, and does not cause such universal abolition of function.

We may not fix the duration of cirrhosis: first, because we never know exactly when it commences; secondly, because the course of the disease may be interrupted fatally (by a hemorrhage, or as the result of pressure of ascites upon the heart and lungs, etc.), or conservatively, by arrest of the process in the first stage, or in the beginning of the second. While it is safe to say that the prognosis is bad, it is dangerous to proclaim that the patient must die soon, or must die at all of the disease. Cases are now abundantly on record, and they may be recalled in the experience of every clinician, where the disease process has been brought to a stand, and the patient has survived for years to smile upon his physician for the rest of his days.

The *indicatio causalis* in the treatment of cirrhosis is total abstention from alcohol. The time may come when the patient will need some support, and when the light Rhine wines, or even a little beer, may be allowed; but any stronger drink must stand absolutely under ban. The diet should be light and nutritious, on a basis of milk and other animal food. A few drops of Fowler's solution, after meals, will help its digestion, absorption, and more especially assimilation.

As for drugs, in general, they may meet the symptoms only. With any knowledge of the anatomy of the disease who would expect to cure it? A stomachic tonic, nux vomica, a dilute mineral acid, hydrochloric, may be written *ut aliquid faciat.*

The only remedial agent that merits the name is puncture of the abdominal wall, and release from the abdominal dropsy. Early and frequent puncture is the result of the testimony of those who have had most to do with cirrhosis. Murchison, especially, is emphatic in its praise. To wait until life is endangered on the part of the heart, and lungs, and kidneys, is to let slip the only chance of arresting the disease. The release of the dropsy sets all the absorbents free. The peritoneum cannot pick up fluids under great pressure. Moreover—and this is the main advantage—the relief of the pressure renders possible the establishment of the collateral circulation, a process to be favoured in every way. The removal of the cause of the disease by abstention from alcohol, and the removal of its worst effect by relief of the dropsy, gives the patient the full benefit of the knowledge we get from pathogeny and pathology. Purgatives, like the salines, diaphoretics like jaborandi, diuretics like digitalis, tonics like iron, may all meet indications at times in the earlier history of the disease, but paracentesis will substitute all of them when ascites is fully declared. Not only are the lungs relieved in this way, Murchison says, but by the removal of pressure from the portal and renal veins the secretion of urine is increased. "I have known hemorrhage from the bowels," he continues, "arrested by paracentesis in cirrhosis, and it is a common observation that patients with much ascites, who, notwithstanding the most powerful diuretics, have been passing only a small quantity of urine containing much albumen, will, after paracentesis, and independently of drugs, void large quantities of urine free from albumen." The same author quotes the experience of Dr. Lyons, of Dublin, in a case which he tapped thirty-six times, at intervals of three or four weeks, withdrawing 14 to 16 quarts on each occasion, with the effect of bringing the disease to a stand at the end of one year after the last operation.

Thus, you may hope to hold the disease in check so far as the mechanical evils are concerned. Unfortunately, over the physiological evils, if we may use such an expression, we have less control. The body must have bile. A successful biliary fistula which carries off all the bile, inevitably leads to the death of the animal by inanition. Should the interstitial process continue, which it does in the rule, the liver cells are finally killed, bile is no longer formed, and death by starvation results. This is the mode of death in most cases of cirrhosis, and death in this way is *lege artis*. But the liver is immense in its size. It has superfluous cells in abundance, and the disease process may be arrested before destruction becomes universal. The patient may not be restored to the state of health, but he may live in comfort for years.

In ancient days, when parchments were scarce, old manuscripts were effaced from them at times, and new writing was put upon the page. It was never so clean and legible as the original sheet, but still it could be preserved and deciphered with care. Such a parchment was called a palimpsest. With more care and study, a practised eye could read, through the new writing, the old, original draft. The liver is a palimpsest at best, for the rest of his days, in a patient in whom has been arrested, but never entirely effaced, the inscription of cirrhosis. I put this statement to you in this way, to impress it upon you that you must not condemn to death a patient with cirrhosis.

SOME EFFECTS OF LONG-CONTINUED LACTATION UPON THE OVARIES AND UTERUS.

BY W. JAPP SINCLAIR, M.A., M.D.,
Hon. Physician to the Manchester Southern Hospital for Women and Children.

GENTLEMEN: During the whole period of pregnancy the breasts are undergoing a gradual process of evolution to prepare them for the performance of their function. Immediately after the completion of parturition there is a sudden acceleration in the progress of evolution, and it is completed within a period varying from a few hours to two or three days. The rapid engorgement of the breasts which is observed in this last stage of evolution may be unaccompanied by any discomfort, but, on the other hand, it often is accompanied by considerable constitutional disturbance, and the local condition may vary through all the degrees of hyperæmia to inflammation, ending perhaps in abscess, and partial destruction of the gland. Stimulation of the breasts at this time has a powerful effect on the contraction of the uterus; and this is only an exaggerated expression of a constant relation between the breasts and the central sexual organs. These are of course well-known facts, and they are mentioned here merely to compare them with the details of what is to a large extent the reverse process, which we are to consider more closely.

As the function of lactation becomes established, the uterus and ovaries undergo a rapid process of involution. This process, as far as the uterus is concerned, can be observed and exactly measured, and is not disputed. The involution of the ovaries also bears some relation to the evolution of the breasts. Menstruation is wholly or partially suspended because ovulation is less active during lactation, and hence impregnation is less likely to take place. This fact is well recognized and acted on by women themselves, but it has received little attention from gynæcologists, probably owing to the tendency to set down a popular belief as a popular error. For example, Mr. Lawson Tait, in his "Diseases of Women," says: "Amongst the working-class of our large towns there is a widely prevalent belief, for which I must say I have discovered no good foundation, that prolonged suckling hinders the mother from becoming pregnant." A well-known law of biology makes a presumption in favour of the popular belief in this instance; and, moreover, a careful inquiry as to the relation in time between weaning and succeeding pregnancy over a large number of cases, taken along with other well-known facts must convince most of the overwhelming proof by which the law of alternate evolution of ovaries and breasts is established.

According to this law, though the apparent exceptions are numerous, a woman does not menstruate perfectly, nor become pregnant, during the time of suckling; and on the gradual cessation of lactation, the re-evolution of the sexual organs becomes gradually complete. This completion can be inferred only from the establishment of normal menstruation and the absence of abnormal phenomena. But when lactation has been carried to excess, we may expect that it has exercised a greater than average influence upon the sexual organs; and when lactation is suddenly stopped, it is reasonable to expect that the final stage of the evolution of the sexual organs will be more rapid than usual, and accompanied by some unusual phenomena. Opportunities of observing whether such phenomena do actually occur are plentiful enough. It is quite a common thing in this part of the country for women to suckle child after child for eighteen months or two years, and to wean them in a day or two. We have occasionally also the opportunity of observing what takes place on the death of a child from acute disease or accident after prolonged suckling. Now, I think we shall find in those cases evidence of a sudden revulsion towards the nutrition of the sexual organs analogous to the final stage of the evolution of the breasts after parturition. The ovaries and uterus became engorged, giving rise to pain and discharges, which may call for medical treatment.

In inquiring into this subject I have not been able to obtain much light from the major prophets of gynæcology. The action and reaction of the breasts and sexual organs, and the consequent influence of lactation as a cause of disease of the latter, appear to have received very little attention, or at least mention. That is, of course, a presumption that the subject does not deserve it. I have looked through Emmet's recent work, and have failed to find a reference to the subject. Thomas, who is usually so full on the causes of disease, merely mentions lactation as a predisposing cause of "chronic cervical endometritis," but why and in what way it acts he does not hint. Martineau, of Paris, in his book on the "Diseases of the Uterus and its Appendages," devotes a chapter to the causes of disease, and as he condescends to mention *Saphisme*, which, it appears, is a lewd habit, practised by some women of the time of Sappho in ancient Greece, and revived in modern Paris, he may be supposed to be exhaustive in his enumeration; yet he makes no mention of excessive lactation. The only explicit reference I find to the subject is in one of the works of Marion Sims. He says: "I know very well we may have menorrhagia from mere debility, from super-lactation, and from some temporary engorgement of the portal circulation, but such cases are not very common, and not usually obstinate." I believe, on the contrary, that menorrhagia from super-lactation, and the other effects arising from the same cause, form a subject too interesting physiologically, and too important in practice, to be dismissed in this summary fashion; and this view I hope to be able to establish by means of the cases which I am to bring under your notice. It is necessary, for the sake of brevity, that I should select from a considerable number of cases, some of which were meant to illustrate various details, only the most striking, and mention merely the relevant circumstances in these.

Case 1.—H. M., aged thirty-six years. Married twelve years; five children, no miscarriage. Husband, labourer. Seen first, April 8, 1879. Symptoms of anæmia lactantium. Weaned child less than three months ago; had suckled him twenty-four months. Menstruation did not return till after weaning; now too frequent, recurring every two weeks, lasting four days, very profuse. Medicinal treatment first adopted, ferri et quin. citr. and pil. rhei co. Next interval lasted three weeks; then menstrual period of five days.

History of Suckling.

First child	born	13 months	after marriage;	suckled	18	months.
Second "	"	2¼ years	after first child	"	18	"
Third "	"	2½ "	" second "	"	18	"
Fourth "	"	2¼ "	" third "	"	18	"
Fifth "	"	2¼ "	" fourth "	"	24	"

Mother never pregnant before weaning. Menstruated once, at least, in the interval; on one or two occasions she menstruated twice before becoming pregnant. This patient was last seen on May 27, when she thought herself quite well again. On January 27, of this year, she applied for a midwifery card, and expected to be confined in February.

This is a fairly typical case of the sequence of suckling, weaning, menstruation, and conception. After the extremely prolonged suckling of the fifth child, menorrhagia follows. The mere exhaustion and anæmia, however well marked, do not account for the symptoms. We have more extreme cases in which no such effects follow when the women are well cared for and manage weaning in a rational way. The following is a good illustration of what a woman may go through without any definite local ailment ensuing.

Case 2.—H. L., aged forty-two years. Married twenty-one years; ten children, no miscarriage. Patient looks robust at first sight, but presents ordinary symptoms of anæmia lactantium. Suckling a child aged thirteen months; has not begun to menstruate.

History of Suckling, etc.

First child	born	March	21, 1859 :	suckled	12	months.
Second "	"	Feb.	8, 1861	"	14	"
Third "	"	Oct.	9, 1863	"	7	"
Fourth "	"	July	5, 1865	"	15	"
Fifth "	"	Oct.	15, 1867	"	12	"
Sixth "	"	Sept.	30, 1869	"	15	"
Seventh "	"	Dec.	10, 1871	"	13	"
Eighth "	"	Nov.	14, 1873	"	10	"
Ninth "	"	June	30, 1875	"	14	"
Tenth "	"	Sept.	2, 1877	"	13	"

Advised to wean child gradually, which was done. An examination of these details will show that the conception never took place until after weaning, and that the interval between weaning and conception varied in duration from one to three months. This patient had a large, heavy uterus, but there was no tendency to prolapse and no history of menorrhagia.

The next case goes to the other extreme: the symptoms appear to have arisen as the immediate result of rapid weaning after the long-continued suckling of the third child.

Case 3.—A. T., aged twenty-four years. Married seven years; three children, no miscarriage. When first seen, complaining of pain in right ovary and constant discharge of blood for about six weeks. Patient suckled the last child a year and nine months, and had not menstruated during that time. Weaned the child in two nights; a week later, began to have pain in the right ovary, and in another week the discharge appeared, and has not ceased since. No history pointing to miscarriage. On examination, the uterus not found enlarged, except a fulness in right half, which is more tender to touch than the other side, and on pressure upwards on right side towards ovary the pain felt there is intensified. No enlargement of the ovary made out. Treated for ovarian menorrhagia and slight cellulitis. History of previous lactation not obtained.

The next two cases are illustrative of what may occur after the death of the child (from acute disease) when lactation has been carried on a considerable time.

Case 4.—E. B., aged forty-one years. Married nineteen years; fifteen children born alive, and three miscarriages. Husband, labourer. Seen first, December 9, 1879. Condition of patient indicates great exhaustion; nervous symptoms indicating anæmia of brain. Has suckled all her children, but some of them for only one, two, or three months. Obscure history of previous floodings after weaning. Last child born eleven months ago: lived seven months; took breast up to day before his death. Patient began to menstruate three days after the child's death, and continued for a fortnight. Since then the hemorrhage has not stopped for more than four days at a time. This patient improved under purely medical treatment, but did not remain long under observation.

Case 5.—L. S., aged forty-three years. Married twenty-three years, fifteen children, four miscarriages. Husband a labourer. When first seen, patient complained of a feeling of weakness about womb, as if it would fall down; profuse leucorrhœa; incontinence of urine under any strain, such as coughing; feeling very weak, and could not walk any considerable distance without bursting into perspiration and feeling as if she would fall down; palpitation, giddiness, rapid loss of vision and of memory since last confinement.

History of Suckling, etc.

First child born	18 months	after marriage;	suckled	16 months.	
Second "	22 "	after first child	"	about 16	"

And so on—every child about twenty-two months after the previous one, and suckled about the same length of time. Patient was always pregnant again before weaning the child at the breast. One child, now aged four years, was suckled two years, the mother going through an attack of rheumatic fever of eleven weeks' duration in that period. The next child was born twenty months ago, and lived nine months. Was suckled up to the day of its death. Patient began to menstruate from four to six weeks after, with severe pain and flooding, for which she was under treatment here. Says she has had two miscarriages since, but is not sure whether one of them was only very profuse menstruation.

In this case the treatment adopted was purely constitutional, and when patient was last seen (March 2, 1880) she was very much better. Had menstruated normally for two successive periods; the tendency to prolapse had entirely passed away, and the urgent symptoms of exhaustion had disappeared.

Case 6.—E. H., aged twenty-nine years. Married twelve years; six children, one miscarriage. Very anæmic. There has been much leucorrhœa for three years; menstruation is now too frequent, and the flow excessive, leaving her weak and nervous, with symptoms which from description appear to be a sort of *petit mal*. Weaned child, aged fourteen months, about two months ago, and has menstruated three times since—weaning done at once when menstruation appeared for the first time since confinement, and that period lasted four days. Speaks of being "flooded away" since then. The next period after patient came under observation lasted six days, and was very profuse. On its cessation an examination was made, of which the following is the note: "Uterus normal to touch: by speculum, os surrounded by ring of highly coloured mucous lining which has tendency to bleed; outside this ring is one of a bluish colour, as if full of venous blood, like a minute varicosis, which keeps all the way round at an even distance from the bleeding ring, except at one point where there is an old fissure. Sound passes easily in normal direction, giving the impression of a cavity wider than normal; canal three-eighths of an inch too long." Patient had suckled all her six children. Three weeks after patient came under observation she menstruated for the fifth time since weaning—that is, in eleven weeks—and the flow continued a week. She was under treatment and observation for two and a half months, and the last note was that she was quite well. The only local treatment employed during the whole time was the introduction into the cervical canal of a bougie of acetate of lead and bismuth.

The next case shows similar phenomena occurring in a woman who had borne only two children.

Case 7.—S. C., aged twenty-five years. Married seven years; two children, no miscarriage.

History of Suckling, etc.

First child born 2 years 9 months after marriage; suckled 16 months.
Second " 2 " 10 " after first child " 17 "

After the birth of the first child patient menstruated regularly, never missing a period until she became pregnant again. After the birth of the second child she remained six months without menstruating, and was regular until after weaning the child when seventeen months old. She applied for advice about eight weeks after weaning. She complained then of pain in back and pelvis, with a sense of dragging and discomfort at the anus; had menstruated a fortnight after weaning, and again two weeks since; each time there was hypogastric pain before discharge appeared, and the period was longer and discharge more profuse than usual. On examination, uterus felt enlarged and rather low, tender to touch posteriorly; os patulous, with erosion round it. Sound passes easily normal distance. First notes taken on September 10. On the 19th patient began to menstruate again, and the flow continued very profuse till the 24th. Began again on the 29th. When patient was last seen, on November 7, menstruation had been normal since last date, but an aching continued about the right ovary.

Case 8.—This is a case in which there existed before weaning symptoms of exhaustion similar to those already described. It was to be expected that menorrhagia or some symptom of engorgement of the sexual organs would occur if weaning were delayed and conducted injudiciously. The patient was kept under constitutional treatment while the child was gradually weaned. E. F., aged twenty-nine years; married eleven years; six children, no miscarriage. Suckling child aged eight months; menstruated once last month.

History of Suckling, etc.

First child	born	February	1, 1868;	suckled	12	months.
Second	"	January	15, 1870	"	12	"
Third	"	March	12, 1872	"	10	"
Fourth	"	March	17, 1874	"	12	"
Fifth	"	November	30, 1875	"	9	"
Sixth	"	January	4, 1878	"	9	"

The last child was weaned while the mother was under treatment. Patient seen occasionally for two months after weaning completed, and she was then quite well. This is a merely negative case, but, considering the rapidly recurring pregnancies and long-continued lactation—more than five years of the eleven years of married life—and the consequent anæmia and exhaustion, it is not without value to contrast with other cases.

Now, leaving menorrhagia and allied conditions, let us consider a case of a different sort.

Case 9.—F. C., aged twenty-eight years. Married eleven years; four children, two miscarriages. First seen May 20, 1879. Complaining of a bearing down for four months, and on examination the uterus was found completely prolapsed, with a large ulcer on the posterior surface of the cervix. Patient had been a washerwoman ever since her marriage, but never had any bearing down until the time stated. Was never delivered with forceps, but says she was "a good deal torn" in second labour six years ago. Perineum bears marks of having been ruptured to verge of anus.

Until the beginning of September attempts were made by pessaries and various applications to remedy the ailment, without success. It was then proposed, considering the patient's age, to operate in order to contract the vagina and improve the perineum. To this the patient consented, and was about to be admitted to the hospital when an unexpected difficulty arose. She was suckling a child twenty-two months old. At the time the patient applied for advice the case was so evidently one of prolapse that no questions had been asked about lactation, and it must be confessed that the endeavours to find a sufficient mechanical treatment had taken away attention from the patient's condition in other respects. By this time several cases of the sort already described had received attention, and it seemed probable that in this case the atony due to long-continued lactation had something to do with the prolapse. Patient was advised to wean the child gradually, but she completed the process in less than a week. On September 16, a week after complete weaning, she reported that the womb had not come outside, and she felt better. On the 23d there was only a slight dragging, no prolapse. On October 1 she began to menstruate for the first time since her last pregnancy, and the womb had completely returned to its normal position. On October 28 she reported herself again menstruating normally, and feeling strong and well.

It should be observed in this case that prolapsus occurred for the first time when the patient had suckled her fourth child fifteen months. A sufficient explanation appears to be the following: Under favourable circumstances the involution of the ovaries and uterus had gone on to a greater extent than usual; super-involution of the uterus and atony of its supports gave a favourable condition for prolapse, and the patient's occupation accounts for the rest. The condition of the sexual organs in this case at the time of prolapse would be similar to what we find in women just past the change of life, in whom prolapse is so common. When the child was weaned, the force which was being wasted on the child was directed to the sexual organs, their nutrition received a rapid acceleration, and they soon recovered their normal condition.

Several cases of the same ailment in a much slighter form have come under observation since. One of them was that of a poorly nourished woman who was suckling her second child in the sixth month, and suffering from a dragging of the pelvic organs as if prolapse were beginning. Improvement followed weaning.

Now, considering the infinite variety of circumstances affecting the health of child-bearing women, and the consequent liability for the working of one physiological law to be obscured by other physiological and pathological conditions, it would be rash to state with confidence as proved any general proposition concerning the phenomena which I have described. But if the cases do not establish a proof, they afford a presumption of the truth of the following propositions:—

1. Lactation tends to prevent conception by its influence on the ovaries in retarding their return to the state in which ovulation is perfect.

2. After weaning, the evolution of the ovaries becomes more rapid than it is during any period of lactation.

3. After long-continued lactation, its sudden cessation is liable to be followed by a rapid evolution of the ovaries and uterus, giving rise to symptoms of ovarian and uterine hyperæmia.

4. Long-continued lactation may cause super-involution of the ovaries and uterus, resulting, under favourable circumstances, in complete or partial prolapse of the uterus.

If a *prima facie* case has been established for these views, the germ of truth can be developed, and the erroneous eliminated by further observation. Meantime, what appears to me to give value to the result so far obtained is that it affords some promise of a basis for the rational treatment of a considerable class of diseases of women which are not as yet treated upon any principle whatever. When the internal organs of generation are in a hyperæmic condition, whatever be the cause, one of the most ordinary phenomena is some sort of discharge. Now, it is obviously irrational to try in any case to cure the condition giving rise to the discharge by the application of caustic substances to the most accessible part of the organs affected. But when the hyperæmia and consequent phenomena depend upon the revulsion after lactation, such applications to parts already functionally too active must do positive harm. It would be as rational to cauterize the engorged breasts the day after labour. When symptoms such as those described in the notes of cases are met with, it would be well to ascertain, as mere routine. whether they can have any relation to oversuckling. To establish such a relation is to ascertain the cause of the disease; the treatment, both constitutional and local, can then be carried out with a confidence and precision, and also with a success which does not ordinarily attend the efforts of the gynæcologist when dealing with these rather indefinite ailments.—*Med. Times and Gazette*, Sept. 4, 1880.

Hospital Notes.

Epithelioma of the Rectum removed after a new Plan without injuring the Sphincter Ani; Recovery.

I. C—, aged sixty-four, married, was admitted into St. George's Hospital, under the care of Mr. Rouse, in May last, with an epithelioma of the rectum of about six months' growth, situated on the left side of the bowel, about one inch above the anus. The growth was flat, sessile, of about the area of half a crown. and limited to the mucous membrane and the submucous tissue. The deeper parts felt apparently uninvolved.

On June 17th Mr. Rouse removed the growth in the following manner. A curved incision, an inch and a half in length, was made, just outside to the external sphincter, and parallel to the outline of that muscle. The skin was then dissected up outwards for a short distance, so that the outer circular fibres of the sphincter were exposed. The muscle was then drawn over towards the middle line. By introducing the finger into the rectum, the growth was pressed into the external wound, and it was then cut out, together with that part of the wall of the rectum to which it was attached. In this way an opening, about the size of a half-crown, was made through the bowel. After the closure of the skin wound but a small cavity could be felt, corresponding to the former situation of the growth. The hemorrhage was very slight.

Opium was given in order to keep the bowels confined for some days. The recovery was almost uninterrupted. For some few days slight feculent discharge took place from the wound, but after about three weeks this had completely ceased, and the patient then had entire control over the contents of the rectum. As a matter of fact, scarcely any feces escaped, but the suppuration resulting during the granulation and closure of the cavity possessed a fecal odour. When the patient left the hospital, about a month after the operation, the power of the sphincter was perfectly normal. The general symptoms were much relieved.

Remarks.—The advantages of this method of operating, in suitable cases, are obvious. In the instance described above, it is true, the growth was of small extent and limited to one side of the bowel. There seems no reason, however. why this operation should not be equally applicable to growths of much larger size. The advantage of preserving the sphincter intact is patent; no doubt, in some cases an operation of this nature might advantageously be substituted for complete removal of the lower end of the rectum. Certainly, numerous cases have been recorded where no incontinence of feces followed the latter proceeding: but still this method of operation gives the patient additional security against a highly unpleasant condition, without any additional concomitant risk.—*Lancet*, Oct. 2. 1880.

MONTHLY ABSTRACT.

Anatomy and Physiology.

Regeneration of the Spinal Cord.

Although in some of the lower animals it has been shown that the spinal cord, after division, may reunite, all attempts to obtain this result in the case of dogs have hitherto failed. It is possible that this is to be ascribed to the age of the animals on which the experiments were performed. EICHORST, experimenting upon very young dogs, has succeeded in obtaining union of the cord and partial restoration of function, in a comparatively short space of time. Although successful in only one case, the particulars of the experiments are of much interest.

In three young dogs the spinal cord was divided between the lower part of the dorsal and upper part of the lumbar regions. Immediately after the operation there was, of course, complete motor and sensory paralysis of the parts supplied from the cord below the section, and vigorous reflex movements could be obtained. The wounds were treated on strict antiseptic principles, but thymol was employed instead of carbolic acid, on account of the action of the latter on the nerve-tissues. The first animal experimented on died in twenty-one days, without any return of voluntary power or of sensation in the paralyzed parts. The post-mortem examination showed that there had not been the slightest attempt at regeneration of the divided cord. The ends were three millimetres apart, and were united by a gray translucent gelatinous substance which was in intimate organic connection with each extremity. This intermediate tissue consisted of large round cells, containing nuclei which were deeply stained by carmine, and a finely granular interstitial tissue which could be resolved, by a high magnifying power, into clear granules and fibres. There were numerous capillary vessels, the proper wall and adventitial sheaths of which were permeated with elongated oval nuclei. Nowhere could any trace of nerve-elements be discovered. It was a cicatricial tissue closely analogous to that of the neuroglia. The nerves of the lower extremities presented no structural alteration.

In a second dog operated on in the same manner, a return of voluntary movements commenced at the end of the fourth week. The dog became able to stand, sit, and finally to run 180 feet without interruption, although its movements were distinctly ataxic. Sensibility, however, remained absent. The animal was killed on the thirty-fifth day. A grayish substance, somewhat flattened from before back, had restored the continuity of the cord. The part corresponding to the anterior and lateral columns already presented a medullary aspect. The nerves and muscles of the lower extremities were normal. Microscopical examination of the new tissue in the cord showed it to be permeated by tracts of nerve-fibres, running from above downwards, of which most possessed a medullary sheath. Many of the fibres presented nuclei which had the aspect of being pressed into the fibres from their surface. Non-medullated nerve-fibres were less abundant, and showed a tendency to a varicose condition. The two kinds had no regular distribution. The interstitial connective-tissue presented cellular elements, colouring deeply with carmine, and provided with processes. Besides these, there were two very large cells with double contoured nuclei and large processes, but whether nerve-cells or connective-tissue elements it was impossible to say.

In the third dog, although it lived for 131 days after the operation, there was no renewal of the motor or sensory functions, nor was there any restoration of the continuity of the cord. The extremities were two millimetres apart. In neither animal was there any secondary degeneration in the cord.—*Lancet*, Aug. 7, 1880.

The Cause of the First Cardiac Sound.

It can hardly be said that we are even yet in a position to satisfactorily account for the production of the first sound of the heart. The generally received explanation is that it is composed of two elements, a valvular and a muscular—although physiologists differ upon the exact share taken in its production by the contraction of the heart-muscle, and some even doubt its share at all. A paper was read at the meeting of the Paris Academy of Medicine on August 31st, by M. ROSOLINO, of Athens, in which (so far as we know) an entirely novel and not unreasonable explanation was broached. This observer maintains that the sole cause of the first sound is the vibration of the chordæ tendineæ in the systolic eddy of the blood-stream. He argues that if it were due to the flapping together of the valve-cusps, it should be produced mechanically by simple traction on the cusps by the cords; but experiments on the human and equine heart fail to bear this out. A simple membrane which from being lax is suddenly stretched produces a sound; but the valve-cusps exist under more complex conditions—since they are more or less fixed by the chordæ, which are inserted not only on their free margin, but also on their surface. The cusp is not therefore free to move in its whole extent, like an unattached membrane; and it is rendered tense by the general contraction of the papillary muscles. Nor is the first sound due to the passive closure of the valve by the blood-column. VALENTIN thought this might be the case, and endeavoured to prove it by showing that a similar sound was produced by suddenly distending with fluid a coil of collapsed intestine; but he could not have obtained it had he artificially enlarged the calibre of the intestine previously, and then stretched its walls. If the sound is abolished by hooking up the valve, it is because the procedure also destroys the meshwork of the chordæ tendineæ. Again, M. Rosolino has produced a similar sound by projecting a current of water over cords attached at both ends, and disposed like the chordæ tendineæ. He rejects the muscular hypothesis, not from his own research, but by the facts advanced by CHAUVEAU and FAIVRE. Nor is the theory of its production by the friction of the blood against the walls of the auriculo-ventricular orifice tenable, since in that case the bruit produced in aortic constriction, where this friction would be most developed, should partake of the characters of the first sound instead of a blowing character. The ventricular wall, tense and solid as it is, cannot vibrate like the chordæ, which from their tenacity, their tension, and their freedom from attachment except at the extremities, are in a condition to allow of true vibrations. As stated above, we are not aware that this explanation has been before offered. It is ingenious and worthy of consideration, but at the same time it must be obvious that in cases of simple regurgitation from dilatation of the cavity, the condition of the chordæ may be almost unaltered, and yet the first sound will be abolished, or rather replaced, by a murmur; and it is difficult to entirely throw over the view that the actual impact of the cusps, and their sudden tension during systole, is not a great element, if not the sole cause of the sound.—*Lancet*, Oct. 2, 1880.

Vaso-motor Action.

The influences which determine the condition of the bloodvessels, their dilatation or contraction, are of extreme importance. Current opinions of the nature of these influences have largely dominated theories of both healthy and morbid action, and every new fact regarding them is of the greatest interest to both the physiologist and the pathologist. A series of investigations by Dr. W. H. GASKELL, which have been carried on in the physiological laboratory at Cambridge, and lately described to the Royal Society, constitute an important addition to our knowledge, and furnished the subject of one of the most interesting demonstrations given at the recent meeting of the British Medical Association. Although their greatest interest is in relation to the peripheral vessels, the observations deal primarily with the states of the heart. Complex as the mechanism of cardiac action is, the apex of the frog's heart presents much more simple conditions, in that it is, so far as has been ascertained, destitute of nerves or nerve-cells. It thus presents a favourable object for the investigation of certain phenomena of vascular action. It has been hitherto believed that all inhibiting or dilating influences on both heart and vessels depend immediately on the nervous system. In accordance with this view, if the nerveless lower part of the ventricle of the frog is physiologically separated from the upper part by a ligature, it ceases to beat, even though, by a canula previously introduced, the frog's own blood is supplied to it. But Meronowicz has found that if an artificial blood solution is supplied to it, or it is stimulated by the constant current, this nerveless apex will recommence its rhythmical contractions; and Foster has further ascertained that the same effect is produced when the heart is supplied with the frog's own blood, but the pressure of this is increased, as by clamping the aorta. Hence, if the stimulation afforded by a mere increase in the intracardiac pressure will induce rhythmical contractions in a nerveless heart, we must regard the view that the action of the muscular walls of the vascular system depends solely upon nervous influence as at least open to reconsideration.

It has been lately ascertained that a dilute alkaline solution will re-excite contractions in the isolated and quiescent apex. This effect was ascribed to the removal of some obstruction. But the suggestive fact has been ascertained by Gaskell (employing Roy's tenometer, by which variations in the size of the cavity are recorded) that the contractions so excited are presently arrested by the heart passing into a condition of tonic spasm. The relaxation between successive beats becomes less and less, and the heart apparently stops in systole. It is not a state of tetanus—*i. e.*, of rapidly recurring contractions—but apparently one of "idio-muscular" contraction or tone. If a saline solution is passed through the heart, it will frequently remain without beating, and then sometimes the alkaline solution may be observed to cause a gradual tonic contraction without any rhythmical beats. It was next found that a dilute acid solution (of lactic acid) had an action precisely opposite to that of a dilute alkaline solution. The ventricle was quickly brought to a standstill in the position of complete relaxation. The effect of neither acid nor alkali is permanent; in either case artificial blood solution is able, subsequently, to cause contraction differing in no way from the normal. The actions of the acid and alkaline solutions are not merely opposite, they are actually antagonistic. If, by means of an acid solution, the beats have been lowered in force, they are quickly restored to the normal by an alkaline solution, and *vice versâ*. Dr. Gaskell has further ascertained that certain poisons act on the heart as does the alkali, while others act as acids. The antiarin (the poison of the upas tree) and digitalin act as do alkalies, causing an increased tone, irrespective of contractions—a tone which ultimately renders contractions impossible. Muscarin, on the other hand, acts as the acid. Pilocarpin also acts like the acid, while atropin acts in the same manner as the askali.

Further investigations have brought out the important fact that alkaline and acid solutions act upon the muscles of the smaller arteries in the same way as upon the cardiac muscle. The observations were made upon the mylo-hyoid muscle of the frog, after pithing, and division of the mylo-hyoid nerve, to eliminate all nervous influence. Solutions were sent through the vessels at a constant pressure, and provision made that the modification in the heart's action should have no effect on the pressure in the vessels. The lactic acid solution produced always an enlargement in the calibre of the arteries, and the flow through them was proportionately more rapid. The alkaline solution caused invariably a diminution in size, usually to absolute closure, with a corresponding obstruction to the flow through the vessels. Moreover, the same antagonism of the two solutions was found to exist for the vessels as for the heart. Although lactic acid was employed in these experiments, it was ascertained that the effect of acetic acid was exactly the same.

Hitherto, as we have said, the condition of the heart and smaller bloodvessels has been regarded as dependent solely on the influences exerted through the vaso-motor nervous system. These experiments show that local influences, the nature of the fluid surrounding the muscular fibres, also affect their condition. Their tonicity is augmented by the increased alkalinity of the fluid, is diminished by its lessened alkalinity. Functional activity is everywhere attended with vascular dilatation, by the mechanism, it has been hitherto assumed, of the vaso-motor nerves. But if the state of the muscular tissue of the vessels may be modified so largely by the fluid around them, may not the products of the activity of the organ determine, by local action, the dilatation of the vessels? Dr. Gaskell ingeniously argues that it is *à priori* probable that it may be so, from the structure of the vessels, the muscular fibres lying immediately *outside* the impermeable elastic lamina. It is in the highest degree probable that the lymph fluid of muscles is rendered less alkaline by the chemical products which result from muscular action. In the brain and pancreas the same conclusion is also probable from recent researches, and these facts suggest that it is true of all tissues. According to some investigations by Klug, oxygen strengthens, carbonic acid lowers, the cardiac pulsations, and alkalinity promotes oxidation. It is probable, then, that throughout the whole vascular system normal tone and rhythmical action are dependent in part upon the due oxygenation and alkalinity of the fluid supplied to its muscular tissues, while, on the other hand, the tonicity cannot be maintained or the rhythmical action continued, when that fluid is overcharged with such products of tissue metamorphosis as lactic and carbonic acid.

Besides its visible pulsations, the muscular tissue of the heart varies much in its condition of tone, as these observations demonstrate. If in the normal state the relaxation between the separate contractions is nearly complete, and the cavity closed for a definite time at each contraction, then with a greater tonicity the period of closure would be longer, the intermediate dilatation would be less complete. With less tone, the cavity would be closed for a shorter time, or incompletely closed at each contraction, and the diastolic relaxation greater. To the latter condition, long recognized theoretically in cardiac pathology, Beau many years ago gave the inexact term of "asystolie." When the ventricle of the frog is tied, atony is produced; the alkaline blood solution gradually improves its tonicity, as tracings show, until spontaneous pulsation result.

It is unnecessary to point out how immediate and important is the application of these facts to the physiology and pathology of the whole vascular system. It is clear that many phenomena now believed to be produced by the agency of the nervous system may be really independent of it. The vaso-motor nerves exert their influence, profound and extensive, but the tissue elements which they control have also a power of independent action. To determine the relative potency and place of the two modes of vaso-muscular influence, and the relation between their excitants, must be the next steps in the solution of the problems opened up by these researches. The facts already ascertained are of the highest importance and suggestiveness, and, elicited as they are with great care and by a most difficult investigation, their discovery does the highest credit to English physiology.—*Lancet*, Sept. 18, 1880.

Materia Medica and Therapeutics.

Recent Researches on the Action of Drugs.

The problem of the antagonism of poisons, which seems destined, for a long time, to be a *quæstio vexata*, has been re-examined by Mr. J. N. LANGLEY, at Cambridge, in reference to certain statements of Rossbach. The latter affirms that when a tissue has been paralyzed by any one alkaloid it can neither be stimulated nor restored to its normal condition by any other alkaloid. In the submaxillary gland, for instance, if the chorda tympani nerve has been paralyzed by atropin, no amount of physostygmin or pilocarpin can, according to him, make it again irritable. He holds that in glands there are two parts to be considered, the nervous and the glandular part, that small doses of alkaloids affect only the nervous part, while large doses affect the glandular part in addition. After atropin has paralyzed the chorda tympani, pilocarpin may still affect the gland cells, but they cannot be affected by it if the dose of atropin was sufficiently large to affect the glandular cells also. Langley has ascertained certain facts which militate strongly against this view. If a small quantity of atropin be injected, the secretion, which is arrested, can be restored by pilocarpin. If a stronger dose of atropin is injected, the same dose of pilocarpin will no longer restore the secretion. Hence, according to Rossbach, this large dose of atropin has affected the gland cells as well as the nerve. But Langley finds that a still larger dose of pilocarpin will again restore the secretion. Thus, whether the larger dose of atropin acts on the cells or not, the pilocarpin must have been antagonistic to it.

Certain recent researches into the effect of large doses of strychnia have brought to light some most remarkable facts. In poisoning by this agent the convulsions and toxic action are remarkably lessened by artificial respiration. This was first shown by Rosenthal, who asserted that double the ordinarily fatal dose was necessary, under these circumstances, to cause death. Experiments which, in the main, confirm these statements have been made by Leube, Pauschinger, and Buchheim. M. RICHET, however, has recently informed the Académie des Sciences of the startling fact that when artificial respiration is maintained, a dose of strychnine 100 times that which is usually fatal may be administered without causing immediate death, and that the effects are altogether different from those which result from ordinary doses. The quantity of strychnia which is fatal to a dog of ordinary size is two or three milligrammes. If one centigramme is injected beneath the skin, or into the saphenous vein, of a dog, in the trachea of which a canula has been placed, the animal is seized in about a quarter of a minute with a violent convulsive attack, which would be fatal were it not for artificial respiration. Under the latter, however, the attack ceases in a few seconds, and the heart, after a period of irregular action, resumes its normal pulsations. Still larger doses of strychnine can be thus injected without causing the death of the animal. The toxic phenomena vary according to the dose injected. There is first a tetanic period, and later a convulsive stage characterized by violent, incessant, spasmodic contractions of nearly all the muscles. A little later, when the quantity of strychnine injected exceeds one centigramme per kilogramme of body weight (say one decigramme, a grain and a half, for an average-sized dog), a stage occurs which may be termed choreic, marked by violent rhythmical shocks, recurring at intervals of three or four seconds, and separated by periods of almost complete resolution. When the dose exceeds four centigrammes per kilogramme of body weight (say half a gramme, or seven grains, to a medium-sized dog), the choreic shocks do not occur; there is a final stage of complete resolution, when reflex action is abolished, spontaneous respiratory movements have ceased, and the heart contracts with frequency but regularity. The pupil, dilated at the onset, becomes strongly contracted. Arterial blood pressure, raised at the commencement of the poisoning, gradually falls, and the rectal temperature varies correspondingly, rising during the convulsions to 105° or 106° F., to fall to 96° during the period of resolution. Dogs and rabbits, to which these large doses have been given, may be kept alive four or more hours by artificial respiration. If the latter is interrupted for a few seconds, say for half a minute, the heart stops, and the animal is dead. Loss of blood, even of a small quantity, will also cause death. In order to insure success in these experiments, the strychnine has to be injected with a certain slowness, an hour being given for the injection of half a gramme (seven grains). The artificial respiration must be vigorous, and success is more readily obtained with rabbits and small dogs than with larger dogs. If instead of these large doses, very small quantities are employed, say one milligramme per kilogramme of body weight, death occurs rapidly by syncope. The cardiac failure is not at first fatal, but after three or four attacks the animal dies. When the dose injected is fifty times as much these syncopal attacks do not occur, and it can then be ascertained that the pneumogastric has scarcely any action upon the heart. The muscles preserve their normal irritability. The action of the motor nerve is lessened, but is not abolished. Thus the complete absence of spontaneous movements is to be ascribed to the effect of the strychnia upon the spinal cord, rather than to the loss of the functions of the motor nerves, or of their terminations. The animal is in a condition analogous to that produced by chloral or alcohol. We cannot, from these experiments, derive much hope of dealing more successfully with strychnine-poisoning. As the poison is eliminated, and its dose thus lessened, its effect upon the heart increases, and death results from syncope. But in cases in which it is important to prolong life for a few hours, this might be effected by prompt tracheotomy and vigorous artificial respiration.

Bromide of ethyl has been found by M. Rabuteau to be an efficient internal remedy, chiefly as a substitute for chloroform, over which, however, it does not appear to possess special advantages. Given by the stomach, it was found to relieve gastric pain, without affecting the appetite. Inhalations readily relieve convulsive cough, and, introduced on cotton-wool into the external meatus, it relieves the pain of otalgia without causing any irritation. Claude Bernard showed that the vapour of chloroform and of ordinary ether hinder the germination of seeds, and M. Rabuteau has found that it is equally true of bromide of ethyl and of bromide of amyl. He finds also that all the ethers have the same effect. The experiments were made with cress seed. But the property of germination is merely restrained. Seeds kept for thirty-seven days exposed to the vapour of bromide of ethyl or bromide of amyl, germinated, when placed under proper conditions, in two days. The question then presents itself, Have these substances a similar action upon plants which are in full progress of growth? Growing cress was exposed for two hours to an atmosphere saturated with vapour of bromide of ethyl; it then appeared feeble, the leaves hanging down, and it continued in this condition for a day or two, and then revived, but exhibited considerable retardation in its growth compared with other plants of the same age. The leaves of heliotrope become brown, and die in the course of two hours. Acetate of ethyl is somewhat less powerful. Cress lives after it has been exposed to the vapour for three hours, but does not survive an exposure of six hours. Heliotropes are only killed by an exposure of three or four hours. The action of acetate of ethyl is also correspondingly less active in animals.

The effect of salicylic acid on muscular contractility has been studied by M. LIVON. Frogs poisoned by this substance present tetanic phenomena. Tracings obtained from the contracting muscles show that the salicylic acid causes an increase of excitability, followed by a considerable diminution and by an irregularity in the latent period. The tetanus which occurs may present two forms. One resembles closely that which results from electrical stimulation, and a second, altogether different, which presents a rhythmical character. In the latter the muscle is in the condition which has been termed "contracture," which continues until the muscle is exhausted, and will no longer respond to faradization of the sciatic nerve. This exhaustion is apparently not due to any effect of the drug upon the muscles; its action seems to be solely upon the nerve centres. The phenomena of the rhythmical tetanus lead M. Livon to believe that the rhythmical action of the heart is not due to any peculiarity in its muscular structure, but solely to its different mode of stimulation.

The inutility and even harmfulness of salicylate of soda in typhoid fever was well established, both in this country and in Germany, soon after the introduction of the drug. Objections to its use in this disease will not be lessened by a recommendation of it recently made by M. Hallopeau, since he had three deaths in twenty cases. M. Labbé has tried it in erysipelas and found it useless.

Sulphocyanide of potassium has been regarded as a "muscular poison," but this opinion is opposed by some experiments of Dr. J. V. LABORDE, the results of which have been described in a series of articles in the *Gazette Médicale de Paris*. He first ascertained that a relative tolerance could be established when the dose does not exceed a gramme; and then, by almost daily administration, he kept an animal under its influence for more than six months. The general health was but little disturbed until the end of the fourth month, when considerable emaciation occurred, and little food was taken. The condition of muscular contractility examined in the thigh or leg at different periods, never presented the least alteration appreciable by any ordinary means of investigation. The cardiac pulsations lessened notably in force and number in accordance with the depression of the nutritive functions. The animal appeared, however, to be in no danger of death, when it suddenly succumbed to a comparatively trivial operation, the intravenous injection of water. From this and many other experiments M. Laborde concludes that the muscular contractility is not primarily or directly affected by the sulphocyanide of potassium.

Euonymin is a drug which, although of some previous repute in America, was introduced to the profession in England mainly by Dr. Rutherford's investigation into its power as a cholagogue. It has been little employed in medicine, but a case in which pseudo-membranous colitis was treated by it successfully has been published by M. BLONDEAU. The case had resisted many courses of treatment, but disappeared in six days on five centigrammes of euonymin night and morning.—*Lancet*, Oct. 2, 1880.

Effects of Salicylic Acid on the Temperature.

Prof. DEPLATZ, of Lille, in a paper laid before the Académie de Médecine (*Bull. de l'Académie*, Sept. 7), arrives at these conclusions: 1. Salicylic acid, administered in sufficient doses to the subjects of fever, always has the effect of temporarily reducing the temperature. 2. This temporary reduction may be maintained and increased by the administration of new doses, and by aid of this agent we are enabled to moderate at will the temperature of the sick. 3. Doses of the acid hitherto considered as poisonous may be exceeded without danger, patients being able to take for several days in succession eight, ten, or twelve grammes. 4. The rectum is the best channel for the introduction of the acid, and each enema should not contain more than two grammes. These conclusions are based on five cases of typhoid, one of variola, one of puerperal peritonitis, and several of phthisis. They are also supported by experiments on animals.—*Med. Times and Gazette*, Sept. 25, 1880.

Homatropin Hydrobromate as a Mydriatic.

Dr. Henry S. Schell, Surgeon to Wills Hospital, has recently been making some observations upon homatropin hydrobromate as a mydriatic, from which the following conclusions appear to be justified:—

1. Homatropin hydrobromate is not well adapted to the treatment of inflammatory or traumatic affections of the eye, on account of the conjunctival irritation it produces.

2. It is especially adapted to the production of that temporary dilatation of the pupil and paralysis of the ciliary muscle which is so often required in examining the condition of the refraction.

3. The best solution to use is one containing sixteen grains to the fluidounce of distilled water. From one to five drops of such a solution may be required to produce the desired effect, according to the strength and activity of the ciliary muscle.

4. Under the influence of a full dose the pupil attains its maximum dilatation in about twenty minutes.

5. With a full dose the accommodation begins to fail in about twenty minutes, and is usually totally suppressed in a half hour, although exceptional cases may require an hour. This total suppression lasts about three hours; the accommodation then gradually recovers itself, and is fully in action again at the end of from ten to thirty hours from the time of the last instillation.

6. The local action of the mydriatic is not accompanied by any unpleasant effects upon the general system.—*Philadelphia Med. Times*, Oct. 9, 1880.

On the Application of Iodoform in Gynæcological Diseases.

Dr. Martin, of Berlin, communicates a paper to the *Centralblatt für Gynäkologie* (No. 14, 1880), in which he gives the results of a series of clinical experiments on the use of iodoform in various gynæcological affections. In the outset, he refers to the recommendations of iodoform made by Greenhalgh, De Marquay, and Völker, the former of whom was the first to recommend its employment in cancer of the cervix, whilst the latter praised its favourable effects in overcoming the pain and the distressing odour of the secretions in this disease. Next he mentions its employment by Kurtz as an absorbent in abdominal tumours. He then goes on to mention the paper of Kisch in No. 52 *Berlin. Klinisch-Wochenschrift*, in which he publishes the results of the local application of iodoform in over fifty gynæcological cases. Kisch had maintained that in these cases he had found iodoform an extremely active medicine, powerfully favouring the resorption of exudations, exerting a favourable alterative action upon the secretion of the diseased mucosa, and possessing an essentially lowering action on the exalted sensibility of the parts. Kisch employed a solution of one part of iodoform to ten of glycerine, with six drops of oil of peppermint well shaken up. A plug of cotton-wool is steeped in this solution and then applied to the vaginal portion. Some of the solution also was rubbed into the lower part of the abdomen. He affirms that it was especially useful in old cases of chronic metritis. In these, diminution of the hyperplastic swelling, healing of granulations, and arrest of the discharges and neuralgic troubles, accompanied its use. Further, in a few days unmistakable success followed its employment in chronic endometritis, and in papillary and follicular ulcers of the os. He also found it useful in chronic inflammatory affections of the pelvic peritoneum and pelvic connective tissue. In a later paper Kurtz has recorded his experience with it in the treatment of one hundred cases of chronic metritis, cervical ulceration, perimetritis, and parametritis; and claims for it valuable qualities as a sedative to pain and as a prompt agent in favouring the cure of chronic metritis, cervical ulceration, and stimulating the resorption of perimetric exudations. The author then proceeds to give the results of his own observations upon iodoform, which are by no means particularly favourable to the drug. The most satisfactory results were afforded by the application of iodoform in neuralgias at the climacteric period. The pains were distinctly lessened by external application only. In two cases they were completely cured, but it was only used in seven in all of such cases. It was also used in three cases of eczema vulvæ. Martin found it beneficial in cases of carcinoma of the cervix, especially as favouring granulation after operation, and preventing pain. He also found some advantage in cases of adhesive chronic kolpitis, and in kolpitis and endometritis of the neck during pregnancy. In eighteen cases of chronic endometritis there was no observable advantage from the use of the drug. In thirty-nine cases of chronic metritis, with unilateral parametritis or with perimetritis, real benefit followed the use of iodoform for a time. The benefit, however, was only temporary. Similar results followed its application in thirty-one cases of chronic perimetritis and parametritis. The author, in conclusion, regards iodoform as an addition to our gynæcological pharmacopœia, but considers that, so far as his experience leads him, its value ought not to be unduly estimated. The preparation he employs is composed of lard and vaseline mixed, with the addition of two or three drops of peppermint-oil, or some balsam of Peru. In that way the disagreeable smell is better corrected. In the case of some patients the use of the drug had to be given up on account of its disagreeable smell.—*Edinburgh Med. Journal*, Sept. 1880.

Medicine.

Salicylate of Soda in Typhoid Fever and Erysipelas.

At the last meeting of the Société Médicale des Hopitaux (*Gaz. Hebd.*, Aug. 20), Dr. HALLOPEAU read a paper on the above subject. In typhoid fever, he observed, two indications are pressing: to attack the infectious principle, the cause of the disease, and to combat the elevated temperature; and, in general, apyretic medicinal agents are also antizymotics. Liebermeister, of Basle, has treated a great number of cases by antipyretics, and, in place of a mean mortality of 15 per cent. in mild epidemics, he has obtained one of 11 per cent. He commenced with a gramme and a half of calomel, and with the use of cold baths according to Brand's method, and then gave from two to three grammes daily of sulphate of quinine, or from six to eight of the salicylate. He found the temperature rapidly became lower, and was maintained at between 38° and 39° C. Dr. Hallopeau, following this example, gave calomel the first day also, and then administered quinine and the salicylate alternately, only having recourse to the cold baths in great and menacing hyperpyrexia. Some observers have condemned the use of the salicylate after employing it in doses of ten, twelve, or even fifteen grammes per diem; but there is no proof that in smaller doses this salt acts at all mischievously. It should be given in doses of about two grammes a day, and never exceeding four grammes; and even then it should not be continued too long without interruption, and should be proscribed altogether when great dyspnœa is present, or a tendency to hemorrhage. It has been objected that the antipyretic effect of the salicylate is but slight, and even less than that of quinine: but all the thermal curves attached to Dr. Hallopeau's paper show a notable diminution of temperature after the administration of two grammes. He admits, however, that its action is fugacious, and may disappear at the end of two or three days; but then quinine may be administered, and the two agents alternated, avoiding thus an accumulation of the salicylate. In no case has he observed any ill effects produced upon the kidney; and if the salicylate be sufficiently diluted. neither ulceration of the pharynx and stomach nor diarrhœa will be caused. It has seemed in some cases to increase dyspnœa and the disposition to intestinal hemorrhage; and where there is a tendency to these conditions it should not be employed. It has been said that the diminution of the temperature has been the sole effect produced by this agent, without its exerting any influence on the course of the affection; but Dr. Hallopeau has found the disease less grave and of shorter duration than usual. In a series of twenty cases he has only met with three deaths, and in two of these not as a direct consequence of the disease; while in a second series of nine cases they all recovered.

Dr. Hallopeau has also given the salicylate internally, in doses of four grammes per diem, in erysipelas; and, basing his practice on the experiments of M. Bochefontaine, who has shown that this salt is absorbed by the skin and passes into the urine, he has also prescribed the application of compresses dipped in a solution of the salicylate (one in twenty). In an infant, eight months old, the subject of erysipelas of the leg from a slight erasure opposite the knee, after having employed compresses wetted with elder-flower water and sulphate of quinine, which were not tolerated, he obtained by means of the salicylate a rapid amelioration of the general symptoms, the arrest of the erysipelas which had invaded two-thirds of the thigh, and the cure of the little patient. In all the fourteen cases in which this substance was employed, the temperature, at the end of twelve, thirty-six, or at most forty-eight hours, had fallen to its normal height; and among the fourteen cases only one death occurred, and that in an old man who was also the subject of purulent pleurisy. Dr. Labbé stated that he also had employed the salicylate in erysipelas, but had not derived any advantage from it, even in large doses. In his opinion, the regular course of this disease, especially on the face, which had formerly led to its erroneous assimilation to eruptive fevers, entirely depends upon anatomical reasons, such as the disposition of the lymphatic network, or that of some of the cutaneous muscles of the face and neck. It lasts for a week on the face, and longer when it gains the trunk; but the use of the salicylate does not modify its course. In typhoid fever, Dr. Labbé gives enemata with three or four grammes of this substance, which always produce a marked sedative effect and sleep, while disinfecting the stools. Dr. Hallopeau replied that he also employed the salicylate locally in erysipelas, and in six of his fourteen cases, he obtained evident amelioration in twenty-four hours. The cases of erysipelas of the face so treated by him did not last a week.—*Med. Times and Gazette*, Sept. 4, 1880.

Local Treatment of Smallpox Eruption with Carbolic Acid.

Dr. SCHWIMMER, in the *Deutsches Archiv*, describes his method of applying Lister's carbolic acid paste, in smallpox, with the view of preventing pitting. The paste (acidi carbolici 4.0—10.0; olei olivæ, 40.0; cretæ trit. alb., 60.0) is applied to the face upon a linen mask, with openings for nose, mouth, and eyes. Strips of linen suffice for the arms and hands. These applications are left undisturbed for twelve hours, when fresh ones can be substituted. Suppuration is greatly shortened and the intensity diminished. While in parts without treatment the stage of desiccation appeared between the thirteenth and fifteenth day, on the face it set in by the ninth to eleventh day. There was no excessive suppuration upon the face. Upon the commencement of desiccation, the mask was usually removed. Ten to fourteen days after complete desiccation, the skin of the face was free from all traces of the disease; or, at the most, spots of pigment were visible that gradually disappeared.—*London Med. Record*, Aug. 15, 1880.

Break-bone Fever in Charleston.

Dr. F. P. PORCHER furnishes to the *National Board of Health Bulletin*, Sept. 25, 1880, the following account of the mild epidemic of break-bone fever which prevailed during the past summer at Charleston:—

It began, it appears, in the extreme northwestern portion of the city, above Calhoun, near Line and Columbus streets, in what was formerly called the "Neck." Afterwards it seemed to progress into the lower or oldest part, and there is every indication that it is now diminishing.

The earth had been disturbed in the paving of King Street, an extensive thoroughfare running north and south the entire length of the city; and the special section of the city where the first cases were noticed was not in as good a condition as others, being near the marshes and new streets having been opened there; but, though we were at first inclined to search for the causes of disease in these conditions, the simultaneous appearance of the fever in the West, and as we learn in Savannah and Augusta, must exclude such a supposition, and refer it to general and wide-prevailing atmospheric influences.

Besides our own experience, which has been limited on account of temporary absence, we have made diligent inquiries of many persons, of physicians as well as the laity, and learn the following particulars, which we present in default of a more complete report, which will doubtless be made in future.

The symptoms vary exceedingly—some being present and some absent—as follows: The disease generally begins with a feeling of coldness, or by a chill, followed by fever—this, with a temperature ranging from 100° to 105°, lasts generally from 24 to 48 hours, occasionally extending to four or five days, and even in rare cases to seven. Relapses occasional, specially in those who have gone out too early. Headache frequent, generally frontal, from the beginning. Miliary eruptions, sometimes elevated and red, like measles, and the occasional presence of *sudamina over the face, neck, and body;* sometimes the eruptions were confined to the body, and endured for days after recovery. We have seen some examples of slight desquamation—furfuratious or branny in character. Sweating profuse in many persons, though *often absent.* Hence, some physicians are inclined to consider the disease to be *suetle miliare* of a mild form. "Break-bone" is the best name, because pain in the bones and limbs is the most constant symptom. There is often great restlessness during the fever, and in some a feeling of tightness or congestion about the throat, with bleeding in a few cases known to us. Catarrhal symptoms are rarely present, although cough has occasionally existed. Bleeding from the nose not unusual in children, and also increase in the menstrual molimen has been observed. Pain in the back and limbs markedly present, but no decided swelling of joints, no carbuncular enlargements or boils, as in the epidemic of dengue, of 40 years since, or in that of "break-bone," which followed some years subsequently. Weakness and prostration have been very decided, but not nearly to such an extent as in previous epidemics. Some of the physicians consider that there has been a tendency to hepatic torpor or congestion, of no great severity however. We have heard of no cases of decided jaundice. Nausea and vomiting seldom occur.

The disease does not affect all the members of a household, oftentimes only one or two being seized, though we have known six to be taken in one house; in this respect differing from the dengue, as described by Prof. Dickson, and from the epidemic seen by us some thirty years since. Then 10,000 were down; no one was well enough or strong enough to help his neighbour, and one had to learn to walk over again.

It is difficult to calculate the number who have suffered, as very many have not employed a physician; from 2000 to 3000, perhaps, approximates the number.

Very little active treatment has been used; as far as we can learn, as follows: A mild laxative, saline or mercurial, hot teas, nitre, pediluvia, sinapisms, etc., and quinine during and after the attack, upon theoretical grounds, with occasionally mild stimulants. Several persons have recovered with no treatment whatever.

It has prevailed among both races, perhaps equally, and *not a single death is ascribed to this disease* as far as we can learn. The only disadvantage which accrues to those who take it is the time lost and the temporary pain and weakness from which they suffer.

Persons who were in the city and who visited the country had mild attacks. We know of four such; one of these had reached Asheville, N. C., where we saw him. Cases of the fever have occurred in Summerville, thirty miles off, on the line of the South Carolina Railroad, among persons who had never visited the city; others sickened there who had paid flying visits, remaining a part of a day only.

How different all this is from yellow fever, in which a fever of far less apparent intensity produces great changes in the blood and tissues, black vomit, albuminuria, and frequent deaths.

Action of Benzoic Acid in Rheumatic Polyarthritis.

Prof. SENATOR has previously called attention to the excellent results which follow the treatment of rheumatic arthritis with benzoic acid. He now brings forward a larger number of cases which confirm his original statements in regard to the action of this drug. In the earlier investigations, which were made in the beginning of the year 1877, the benzoic acid was employed not only in acute cases of rheumatic arthritis, but also in subacute cases without fever as well as in chronic ones; in the latter class, however, no results were obtained. Twenty-two cases out of a total of forty-six were treated solely by means of benzoic acid or sodium benzoate, which was given to the extent of 15 grams a day. The patients were relieved, in one case after two days of the treatment, in twenty cases after 3.7 days, and in one case, which was treated from the very commencement of the attack with small doses, after eleven days. No relapses or complications were observed in any case. In these cases it was clear that the favourable result was actually due to the benzoic acid, and this was further confirmed by the fact that in a second group of cases, four in number, the affection which had been futilely treated by salicylic acid, was really or apparently cured. In a third group, consisting of six cases, the author found that benzoic acid afforded no relief, whilst salicylic acid was of use. From these data, which are supplemented by fourteen cases in which salicylic and benzoic acids were both employed, Professor Senator concludes that benzoic acid exerts a distinctly favourable action in rheumatic polyarthritis, though it scarcely rivals salicylic acid. Benzoic acid possesses, however, the advantage that it may be given in very large doses. The author therefore recommends that the remedy, or its sodium compounds, be used in those cases in which salicylic acid has failed, and that, if necessary, it be administered in large doses.—*Practitioner*, Sept., 1880, from Frerichs's and Leyden's *Zeitsch. f. Klin. med.* 1, p. 243.

The Pathology of Epilepsy.

The subject of epilepsy appears to be, and in reality is, one of the most difficult that can be met with in the whole range of medicine. Though brought face to face with it in his daily life, the practitioner, as a rule, gives up all attempt to grapple with the problems connected with its pathology. It seems hopeless to try to analyze the strange phenomena which make up the "fit," with which every one is familiar; and his knowledge of the subject usually ends, as it began, by a recognition of the few obvious facts patent to all who are brought into contact with cases of this disease. To pass from this elementary stage to a stage worthy of the name of scientific knowledge, a great leap is necessary—so great a leap, indeed, that until recently few attempts had been made to bridge the chasm; and such as were made, resembled leaps in the dark, guesses at the unknown, rather than the result of the true inductive processes. A few of the grosser features of the intenser kinds of fits were seized upon in the endeavour to elucidate the nature of the fits; but these, though the most obvious, were by no means the most important phenomena present, and their very intensity increased the difficulty of forming a correct notion of the pathological processes which they represented. As time went on, an observer here and there began to analyze more fully the nature of these fits, and faint gleams of light were thrown into some dark recesses of the disease. The onward progress of knowledge was, however, slow and uncertain until Hughlings-Jackson began to make his observations on the slighter forms of fits, and to notice the less obvious characters presented by them. For years he worked at the subject, until he was able to throw a flood of light on the whole question, and to open up vistas, which are now calling for exploration at the hands of those who are devoting their studies in the direction of nervous diseases.

One of the very best contributions that have hitherto been made to the study of epilepsy—we may, indeed, say the best *résumé* that has yet appeared of the views of those who form the vanguard of the neuro-pathologists—is to be found in the three Gulstonian Lectures recently delivered by Dr. Gowers before the Royal College of Physicians. Dr. Gowers has had exceptional opportunities for becoming acquainted with the disease in all its protean forms, and he was able to base his lectures upon the careful personal records of no less than fourteen hundred and fifty cases that had come under his own notice. In dealing with these cases he chiefly adopted the numerical method of analysis, but he also availed himself of the method which has been of such great service in the hands of Dr. Hughlings-Jackson—that, namely, of analyzing carefully the symptoms present in single cases, and endeavouring, by tracing them down to their source, to form some idea of their real significance. The numerical method has been already very largely employed in connection with epilepsy, and the results arrived at by its help, though they have done much to elucidate the clinical history and the prognosis of the disease, have afforded but scanty aid in the explanation of its pathology. Although, therefore, there is much interesting information in those parts of the lectures which rest upon the percentage-frequency of certain conditions and certain symptoms in epileptic patients, it is in those portions in which Dr. Gowers deals with the significance of individual phenomena that we must seek for the more important additions to our knowledge of epilepsy. Some of those who are accustomed to employ the scalpel and the microscope only in their search after the ultimate causation of disease, may say that there is too much of the hypothetical element in the explanations of the pathology of epilepsy offered by Hughlings-Jackson, Gowers, and their school. To these it is only necessary to say that, so far as we are able to foresee, the microscope and the scalpel will afford us but little help in the investigation of epilepsy, and that the only way to arrive at an accurate knowledge of its pathology is to study its clinical features with the aid of physiology, rather than the post-mortem appearances with the aid of anatomy. This, in fact, it is which constitutes the chief difference between the so-called "functional" and the so-called "organic" diseases. In each case there is the physiological and the anatomical side of the disease; but in the one case the physiological side is the more easy of approach, while in the other the anatomical side lies so open for investigation, that it is to this that our chief attention is directed. As was remarked by Dr. Gowers in his first lecture, the convulsive disorders stand out pre-eminently amongst those which can only be studied by reasoning processes based upon accurate clinical observation.

Until quite recently it was almost universally held, in accordance with the teaching of Schroeder van der Kolk, that the seat of the primary lesion in epilepsy was to be found in a vaso-motor centre in the medulla oblongata, and that the fit was due to anæmia of the brain, resulting from the spasm in its vessels caused by some sudden morbid action in this centre. This is, indeed, the view still held by a very considerable number of authorities on the subject; and it is encouraged by the fact that there is a centre in the medulla, which, when experimentally irritated in animals, gives rise to universal convulsion. Universal convulsion is, however, very different from the multiform phenomena—mental, sensory, motor, and organic—which are met with, either separately, or grouped in an endless variety of ways, in epilepsy. The fact that nearly all the forms of action of which the brain is capable may be seen in fits, argues strongly against the hypothesis that epilepsy is due only to a lesion in an exceedingly circumscribed centre; whilst it points as strongly to the probability that the fits are due to some primary morbid condition of brain matter itself, in which case the characters of the fits would vary according as this primary morbid state is present generally throughout the brain substance, or is more or less accurately localized in different parts of the organ. It is scarcely necessary to add that the morbid state would, according to this hypothesis, affect the gray matter rather than the white, the function of the latter substance being merely that of a conductor—all the active power of the brain being seated in the former.

The next question that arises is this: Granted that epilepsy is due to some primary morbid action of gray matter, taking place either in the whole brain or in some portion of it only, what is the nature of this morbid action? The answer to this is fairly easy up to a certain point: The action is identical with that which takes place when the brain is performing its functions healthily; and the morbid nature of the action consists only of this, that it takes place in an irregular and uncontrollable manner. We may indeed borrow the celebrated definition of "dirt," that it is "matter in the wrong place,"—which, when applied to epilepsy, should read, "activity of brain at a wrong time." What the nature of this activity is, we are at present unable to say; nor is it easier to explain why it is thus set in motion without control. The first of these problems will be answered when the physiologists have fully determined the nature of "nerve-force;" the second will, probably, for a long time to come, afford matter for speculation to neurologists. A considerable portion of his last lecture was devoted by Dr. Gowers to the consideration of this question, and he elaborated a highly ingenious theory to explain the occurrence of fits; but this part of the subject can scarcely be considered ripe for discussion except amongst those who are devoting especial attention to the subject, and we therefore pass it over without further comment.

Dr. Hughlings-Jackson has defined epilepsy as "an irregular discharge of nerve-force occurring in any part of the gray matter of the brain or spinal cord." Taking the term in its widest sense, an "epileptic fit" may vary in intensity, from an involuntary twitching in one finger, or a sudden attack of tingling in one foot, up to those severe forms of the disease in which there is profound loss of consciousness and convulsion of every muscle of the body. This is the important fact to bear in mind in thinking over the pathology of the disease; and it will greatly facilitate the comprehension of this difficult subject, if it be thus, so to speak, reduced to its lowest terms. We believe that a very large number of medical men still look upon the expressions, "nervous discharge," "discharge of nerve-force," "discharging lesion," etc., as a mere jargon invented to conceal ignorance. It is possible that these terms may not be the clearest and most expressive that could be found; but if it be once thoroughly understood that they mean nothing more than the irregular action of some portion of the gray-matter of the brain, instead of being a jargon they will be found to contain the pith of the pathology of epilepsy so far as it is at present understood. In the detailed application of Hughlings-Jackson's definition to the various forms of fits, numerous and highly complex problems in physiology and psychology present themselves; but the first desideratum necessary for an intelligent study of the subject is to obtain a firm hold of the truth embodied in the definition, and to be able to apply it to the simpler phenomena of epileptic fits without difficulty. At present we fear the views held by the majority of medical men on the subject of the pathology of epilepsy are of a vague and hazy description. We know of nothing more likely to dispel this widespread darkness than a careful study of the Gulstonian Lectures of Dr. Gowers.—*Med. Times and Gaz.*, Sept. 4, 1880.

Treatment of Diphtheria.

Dr. CALLAN, in the *Proceedings of the Finland Practitioners*, quoted in the *St. Petersburg Med. Woch.* for August 7, states that he has derived so much benefit from the external and internal use of the sesquichloride of iron that he regards it as much a specific for this disease as quinine is in intermittent fever. Locally, he applies one part of the liquor ferri sesquichlor. with one or two parts of water, morning and evening, by means of a thick, short-cut charpie pencil, rotating it against the pseudo-membrane, which after some hours almost always becomes detached, so that the bleeding mucous membrane becomes cauterized. The nose is syringed with a solution of half this strength, and the throat is gargled with milk. From ten to fifteen drops of the sesquichloride are taken in six ounces of water, in teaspoonful doses, every ten or fifteen minutes in the day, and every quarter or half an hour in the night. Cold milk is the best food. The treatment is very troublesome for the attendants, but it is so successful that Dr. Callan states that, since the year 1861, of more than 150 patients he has not lost one. The treatment, however, should be begun early and strongly persevered in. Usually about the second or third day the pulse becomes slower and fuller, and the sticky sweat, which generally accompanies diphtheria, diminishes, together with the febrile temperature. Upon an average, nine days have been required for the cure. When this is accomplished, the greatest care is still required, as sudden movement of the child may cause fainting or even death. [The employment of the perchloride of iron both locally and internally, in diphtheria, is nothing new, though Dr. Callan's energy of employment is perhaps new. Certainly his success is. We transcribe his statement because it is so positive; but it certainly seems strange that, as in Russia diphtheria is depopulating some regions, he has not taken more pains to make so certain a cure known. His own cases, he admits, were mild ones.]—*Med. Times and Gazette*, Sept. 4, 1880.

The Treatment of Pleuritic Effusions.

A physician to a foreign hospital generally has the advantage over an English hospital physician in the number of beds at his disposal. If you want to study a certain class of disease, you are more likely to have the opportunity with a hundred beds than with twenty. Thus we doubt whether a member of any English medical staff could illustrate his remarks on pleuritic effusion by the results of 123 cases treated in his own wards, as Dr. GOLTDAMMER, of the Bethany Hospital, Berlin, does in a lecture delivered before the Berlin Medical Society (*Berlin Klin. Wochenschrift*, Nos. 19, 20, 1880). Of these 123 cases, which were operated on in all 200 times, 19 were purulent effusions, 49 were primary sero-fibrinous pleurisies, and 55 were secondary effusions in patients with phthisis, pneumothorax, typhoid fever, carcinoma, and tuberculosis of the pleura, heart disease, and nephritis. Passing over the cases of empyema for the present, we will speak first of the primary serous effusions. These Dr. Goltdammer divides into abundant, where one whole side of a chest is full of fluid, and moderate and small effusions. The former he invariably taps, not waiting for the onset of dyspnœa, but endeavouring to tap early enough to prevent it. The relief given is immense, and there is often no return of the fluid, especially when the tapping is done early. This was true of eight out of twenty-two such cases treated by him, while in nine others which were tapped in the second, third, and fourth month of their existence, there was a considerable re-accumulation. It is very exceptional, however, for the fluid to attain its former level. The general rule is, that a re-ascent amounting to the breadth of one or one and a half intercostal spaces is detected a few days after the tapping. Dr. Goltdammer takes no account of the presence of fever, not having been able to convince himself that it affects the result of the tapping in the least. It should be noted that he scarcely ever *aspirates* large serous pleuritic effusions, but evacuates them with a trocar guarded by a valve of goldbeater's skin; aspiration he reserves for small collections of fluid. The almost exclusive indication for its use in the latter is protracted absorption. He waits until about eight days after all fever has disappeared, and then, if the effusion shows no diminution, aspirates. Most of the cases of this category, twenty-seven in number, were operated on during the second month; they, as well as the forty-nine cases of extensive effusion, all recovered, and in not a single instance did the serous fluid become purulent. This happy result Dr. Goltdammer ascribes, no doubt correctly, to the care he takes to disinfect his instruments, and to avoid pressing the contents of the syringe in aspiration, back into the pleural cavity. He mentions two cases of secondary effusion where rapid septicæmia followed the tapping; in one of these it was certain that to remedy a partial stoppage of the needle the handle of the syringe had been pushed in, driving part of the fluid in the latter, contaminated by the old oil, etc., of the piston, which it is impossible to disinfect perfectly, into the pleura; in the other case the infection could not be proved, but no other rational explanation of the catastrophe could be found. Dr. Goltdammer observes that he is surprised that the conversion of serous into purulent exudations is not more often met with in practice, seeing how little care is taken by practitioners to use clean instruments. We cannot too strongly emphasize this remark. The great indication for tapping in the fifty-five cases of secondary effusion was dyspnœa, and relief was generally obtained. Some of the patients earnestly begged for the operation to be repeated, and Dr. Goltdammer did not notice that the repetition at all weakened them. The amount of albumen is very small in the comparatively trifling collections of fluid met with in secondary pleurisy. In two cases of phthisis a single aspiration caused complete disappearance of the effusion. In five cases of pneumothorax the fluid aspirated was serous, and not, as is generally the case, purulent. In two of these the lung completely expanded after the tapping. Dr. Goltdammer has also aspirated with success several cases of effusion secondary to hemorrhagic infarcts in the lungs. One point on which he lays great stress is, never to evacuate the whole of the fluid at once. In secondary effusions he does not withdraw more than from half a litre to one litre, and the onset of paroxysmal cough or tensive pains in the chest is always an indication to cease aspiration. In the 200 operations he has altogether performed he has only once had a case of collapse, and this recovered, and not a single case of sudden death. He therefore considers the dangers of tapping and aspiration much exaggerated.

The treatment of empyema is still one of the vexed questions of the day. Antiseptic surgery has done much to render success more certain; but the antiseptic dressing of an empyema and the insertion of a drainage-tube give trouble, and a simpler plan has been long a desideratum. The siphon trocar as used by Dr. Douglas Powell and others, is sufficiently simple, but is open to the objection that if the chest is washed out after drawing off the pus, the same tube being used for both operations, septic matter is liable to enter and infect the pleural cavity. Most of Dr. Goltdammer's cases were treated by incision under the spray and antiseptic dressing, resection of part of a rib being performed in several. The last case, however, to which he refers in his lecture was treated by a new method recommended by Dr. Kashimura, assistant to Professor Baelz, of Tokio, Japan (*Berl. Klin. Wochenschrift*, No. 3, 1880), and which is the simplest imaginable, consisting in puncturing and evacuating the pleural cavity, washing it out freely with an antiseptic liquid, and *then allowing the opening to close*. The instrument (figured by Dr. Kashimura) consists of a canula provided with a stopcock, which closes its outer end after the withdrawal of the trocar, and with two lateral openings to which India-rubber tubes are attached with spring clamps, so that either can be closed or opened at pleasure. Before tapping, these tubes are filled with thymol-water and clamped. When the instrument has been introduced, the stop-cock is closed, and one of the tubes, which dips into a vessel of thymol-water, is opened, and the pus allowed to escape. The first tube is then clamped, and the second, which communicates with an irrigator containing warm thymol-water, is opened, and the antiseptic allowed to enter the pleural cavity. It is then evacuated by the first tube, and the process is repeated until the wash-water returns uncoloured. The canula is then withdrawn and the opening closed. Of course the whole of the instrument is assumed to be thoroughly disinfected before use. The cases hitherto treated by this plan, though not numerous, are eminently satisfactory; all have recovered. Dr. Goltdammer tapped a woman aged forty-one, in a state of great prostration, with an empyema of a month's standing, and removed 700 to 800 cubic centimetres of pus. About two litres of thymol-water were used to wash out the cavity. She was operated on, on February 19, 1880; *eight* days afterwards all traces of the effusion had disappeared and there was no return of it later on. The patient, who had entered the hospital with extreme cyanosis, and with orthopnœa, ascites, extensive anasarca, and slight albuminuria, as well as an unresolved pneumonia of the right base, to which the empyema was secondary, had entirely recovered, even to the restoration of clear percussion and vesicular breathing over the whole right side, on April 10. It is needless to enlarge on such a result. A few years ago, however, we may remark in passing, it would have been considered miraculous. Now, thanks to the antiseptic method, whose beneficent effects are making themselves felt in every part of the field of surgery, we scarcely wonder at it. We recommend the special mode of its application above described to the attention and imitation of our readers.—*Med. Times and Gazette*, Sept. 4, 1880.

—

Fœtal Endocarditis.

The recognition of fœtal endocarditis during intra-utarine life is a diagnostic achievement worthy of note. A girl aged seventeen was admitted into Professor Peter's ward at La Pitié near the end of her pregnancy. An active fœtus could be felt in the uterus. The double sound of the fœtal head could be heard in the usual situation, but instead of the customary *tic-tac*, the first sound was replaced by a blowing murmur, almost immediately succeeded by a sharp sound like the normal second sound, and this was followed by a brief silence. The series was repeated about 130 times a minute. At first the interne, M. H. BARTH (who records the case in *La France Médicale*), thought that the murmur was that described by Naegele as due to the compression of the umbilical cord, but its precise limitation to the area in which alone the sounds of the fœtal heart were heard, and the absence of any uterine contraction which could cause the compression of the cord, convinced him that the sounds must be due to a lesion of one of the cardiac orifices. The murmur was again heard next day, when the labour was actually commencing. The child was born dead, having apparently died during the last period of labour. The child was well-formed, and the organs were healthy, with the exception of the heart, which was enormously hypertrophied, and seemed alone almost to fill the thoracic cavity. It was nearly globular in form, the right half being much larger than the left. The valves on the left side of the heart, and those of the pulmonary artery, were healthy, but the tricuspid valve was the seat of a "plastic vegetative endocarditis," the free edge being thickened, covered with projections, and its surface being uneven. The chordæ tendineæ were shortened and thickened, maintaining the valves in contiguity to the walls of the ventricle, so that it was impossible for them to fulfil their normal function. The right ventricle was dilated and greatly hypertrophied.

The case has a practical lesson. The labour offered no difficulties to which the death of the child could be ascribed, and it was doubtless due to the cardiac lesion. In such a case, in which fœtal endocarditis has been diagnosed, the acceleration of the labour by all possible means is desirable, to afford the child a better chance of life. The mother, it may be noted, had never suffered from rheumatism, and presented, in her history, nothing to which the fœtal condition could be ascribed. Whether she had suffered from syphilis is not noted.—*Lancet*, Sept. 4, 1880.

—

Parasitical Hæmoptysis.

Japan presents, apparently, a fruitful field to the pathologist. We lately chronicled the discovery of a new form of endemic fever by Professor BAELZ, of Tokio, and now, from the same observer, comes a description of a new form of hæmoptysis, of parasitical origin, the symptoms of a disease which Baelz proposes to call "gregarinosis pulmonum." The disease is not only undescribed, but it is apparently unknown even to the native practitioners. Its chief symptom is hæmoptysis. Individuals, who are otherwise healthy, cough up bloody sputa, either continuously or at intervals, for many years. The hemorrhage has no apparent connection with phthisis or any other discoverable lung affection. Beyond the cough and expectoration, no morbid symptom, objective or subjective, is to be detected, even after the disease has lasted ten years. The affection appears to be a common one, for Baelz has already met with nineteen cases, twelve in the last year, and it is probable that thousands of Japanese suffer from it. All the cases hitherto seen have been in men, and for the most part between the ages of fifteen and twenty-five years. It is met with throughout the whole of Japan, but seems to be somewhat more frequent in the south. The sputa have a characteristic dirty-red aspect, and are thin. The red colour depends solely upon blood. A specific parasite is always to be found in it. This is met with in two forms: (1) as yellowish-brown, ovoid bodies of .13 mm. long, and .07 mm. wide. They have a double contour from a translucent wall .02 mm. thick, which, in different positions, appears greenish or reddish, and at the larger end is a kind of cover, at which the cyst opens. The contents consist of delicate jelly-like material, in which are embedded three or five aggregations of smaller bodies. The latter consist (*a*) of spherules about twice the size of a white blood-corpuscle, colourless, with sharp outlines. Around these spherules, and more or less inclosing them, is (*b*) a coarsely granular material, scattered through the jelly, and in it molecular movements may often be seen. When the spherules have left the cyst, they show for a time the same movements, and then become invested with the granular substance, and become motionless. The larger ovoid bodies are clearly psorosperm cysts, and the young spherules seem to be psorosperms similar to those which Waldenburg and Eimer have found in the intestine and liver of the mouse and rabbit. Since these and other observers have ascertained that the bodies we call psorosperms are only a stage in the development of gregarinæ, Baelz proposes to call the disease gregarinosis pulmonum, and the parasite gregarina pulmonum, or, from its colour, gregarina fusca. No opportunity has apparently occurred for investigating the pathological anatomy of the disease.—*Lancet*, October 2, 1880.

Pulmonary Syphilis.

Dr. Reginald E. Thompson, of London, has recently studied sixty well-marked cases of pulmonary syphilis which had occurred in his practice. In all the signs of pulmonary disease of a peculiar character were present; they were associated with symptoms of syphilitic cachexia, and were relieved by antisyphilitic remedies. The signs might be distinguished from those of other pulmonary diseases, and were sufficiently peculiar to establish the nature of the disease. Briefly, these physical signs were dulness of percussion, and a peculiar alveolar rustle (resembling the crumpling of thin paper), with bronchial respiration and bronchophony of varying degree. These signs were not to be classed under the signs of phthisis, and the pulmonary condition indicated by them was notable for an absence of signs indicating destruction of lung-tissue. There was marked dyspnœa occurring after exertion, especially in raising the body upstairs or uphill. Hæmoptysis of small amount was frequently present, and the expectoration was sometimes abundant. These characteristics of the disease were accompanied with thoracic tenderness and other evidence of syphilitic complications. The pathology of the disease was very obscure, inasmuch as the disease was very chronic, and seldom, if ever, fatal; only one necropsy having been made by the author, and in this case death was due to other causes. The morbid condition of the lungs in this case was given in detail.—*British Med. Journal*, Aug. 28, 1880.

—

Syphilitic Disease of the Bloodvessels.

Dr. KARL HUBER, of Leipzig, relates the following case (*Virchow's Archiv.* Band 79, Heft. 3, 1880, p. 537). A woman, aged 22, had enjoyed good health until fourteen years old, when she suffered from scarlatina. In 1876, when she was twenty, she had an attack of left-sided pleurisy. On September 13, 1878, the patient was admitted into the hospital at Dresden with syphilitic ulcers of the genitals, psoriasis palmaris, mucous patches in the mouth, and other symptoms. She left the hospital on December 13, but was again under treatment in January for other syphilitic affections. On both occasions the symptoms disappeared under mercurial inunction. On February 8, 1879, the patient noticed that her urine was thick, and that her legs were swollen. On February 11, she was admitted into the Leipzig hospital, when there was considerable general œdema, and there were also signs of fluid in the thorax and abdomen. The œdema became slightly less under treatment, but soon returned, and remained more or less until death. The urine was always scanty, pale, and turbid, and contained a considerable quantity of albumen, as well as pus-corpuscles, and sometimes casts. Vomiting, diarrhœa, and prostration afterwards came on, and the patient eventually became comatose, and died on May 19th. The post-mortem examination revealed a general diseased condition of the bloodvessels, with wide-spread calcification, which was most marked in the arteries. The liver was lardaceous and fatty. The spleen, great intestine, mesenteric glands, and right kidney were lardaceous. There were pyelo-nephritis of the left kidney, and inflammation of the ureter; cystitis, ascites, and anasarca, with fluid in the thorax and pericardium; embola in the arteries of the lungs; thrombi in the inferior cava and right femoral vein; ulcers of the great intestine and larynx; cheesy deposits, and recent inflammatory infiltrations, with œdema of both lungs. The changes of the vascular system were more extensive in the arteries than in the veins, but all the arteries of the pia mater and brain, and the coronary arteries, were healthy. The other arteries, beginning at the aorta, and extending to the small arteries of the hands and feet, were more or less altered by whitish or yellow patches of thickening, and by calcification, some of the arteries of the extremities being converted into chalky tubes. The lumen of the arteries, in many places, was completely blocked, this blocking being due, in some instances, to the morbid condition of the vessel, in others to thrombosis as well. In the veins there were patches of thickening in the larger branches of the upper and lower extremities, but more in the latter than in the former. The portal veins, and several branches of the pulmonary artery, were also similarly affected. There was calcification, to a limited extent, in the middle-sized veins, but more extensive in the small veins of the extremities, especially of the lower extremities. Some of the smaller branches of the pulmonary arteries were calcified to a slight extent. In some remarks on the case, the author states that the extensive disease of the bloodvessels could not have been caused by age, nor were there any grounds for suspecting the influence of chronic alcoholism. In the absence of other causes to account for it, he considers the vascular change must be looked upon as due to syphilis, although differing widely from the changes hitherto regarded as syphilitic. Dr. Huber, however, admits the difficulty of accounting for the escape of the cerebral vessels, supposing his view to be the correct one.—*London Med. Record*, August 15, 1880.

Obstinate Epistaxis dependent on Cirrhosis of the Liver.

M. **Garnier** relates a case which he observed in Prof. Verneuil's service. A robust man was admitted on account of an epistaxis which had continued for two days, having been arrested from time to time by means of the plug. Prof. Verneuil plugged the nostrils before and behind, and, supposing that it might be a case of intermittent epistaxis, prescribed quinine. The hemorrhage persisted, and ergotine given internally and injected into the ala nasi proved of no use. Digitalis arrested the bleeding for two days, when a minute examination of the man having revealed the existence of cirrhosis of the liver, a large blister was applied over the hepatic region, and the epistaxis was definitely arrested.—*Med. Times and Gazette*, Sept. 4, 1880.

On the Cause and Treatment of the Bad Odour sometimes associated with Excessive Sweating of the Feet.

Dr. **George Thin** has recently made a fruitful investigation of this subject, the report of which is published in the *British Medical Journal* for Sept. 18, 1880, and from which the following is abstracted:—

The patient who has afforded me the opportunity of investigating the cause of the smell is a young woman, aged 22, who has suffered from evil-smelling feet, with soreness of the heels, for several years. Her hands are usually moist, or even wet, but are always odourless. The smell from the feet is not constant, disappearing in dry bracing weather, and reappearing when the weather is moist and depressing.

The first experiment I made was to subject the soles of the stockings and boots to the action of an antiseptic solution. The success was complete, the odour being entirely banished. The antiseptic precautions having been soon neglected, the smell returned, and I took the opportunity of investigating its cause more minutely.

The sole of the stocking, a few hours after it was put on, was found to be quite wet; and a stocking, if worn for a whole day, was so extremely offensive that, when held close to the nostrils, its overpowering fetor was comparable to that of putrid blood. The inside of the boot was equally wet and offensive; but, at the very time that the stocking and boot smelt so strongly, the heel itself, exuding moisture profusely, had no disagreeable odour. The sole of the heel was reddened and tender, and macerated around the edge, like a washerwoman's palm.

The reaction of the moisture in the stocking and in the sole of the boot was alkaline, that of the moisture exuding from the skin of the sole of the heel faintly alkaline, whilst that of the perspiration of other parts of the body was acid.

The fluid from the sole of the heel was thus shown to be not pure sweat, the faintly alkaline reaction being doubtless due to the serous discharge accompanying the eczema set up by the local hyperidrosis.

The fluid in the sole of the stocking was found to be teeming with bacteria forms, the nature and development of which I have carefully investigated. These investigations have produced results of some scientific interest, which I have communicated to the Royal Society.[1] The rapid development of bacteria in the fluid which exudes from the soles is doubtless favoured by the alkaline reaction produced by the mixture of serous exudation with the sweat.

The treatment instituted in this case is as simple as it has been effective. The stockings are changed twice daily, and the stocking-feet are placed for some hours in a jar containing a saturated solution of boracic acid. They are then dried, and are fit for wear again if it be desired. The boracic acid effectually destroys the smell. But to kill the bacteria in the stocking is not enough. The leather in the bottom of the boot is wet and sodden, and smells as vilely as the stocking. This difficulty is got over by the use of cork soles. I directed my patient to get half a dozen, which she finds sufficient. A pair must only be worn one day unchanged; at night, they are placed in the boracic jar, and are put aside the next day to dry. If these directions be accurately carried out, the evil smell is perfectly destroyed.

---

[1] On Bacterium fœtidum: an organism associated with profuse sweating from the soles of the feet. Proceedings of the Royal Society, No. 205, 1880.)

The boracic acid solution is an excellent application to the painful skin in these cases. When the tender skin of the soles is washed with it, a sensation of coolness succeeds the feeling of heat and tension which are the usual accompaniments of the eczematous condition associated with the smell, and the skin becomes harder and loses its abnormal redness.

The bacteric fluid would seem to act as a direct irritant to the skin. My patient assures me that, if she wears stockings which have been dried without being disinfected, irritation is speedily felt; and that the cork soles, if worn a second day without having been purified, act in a similar way.

Surgery.

Case of Syphilis of the Conjunctiva.

Dr. Jules Galvani, of Athens relates (*Gazette Hebdomadaire*, May 21, 1880) the case of a man, aged 40, who complained of trouble in his left eye, which had come on gradually. On examination, the eyelid was found to be swollen and partially closed. The ocular conjunctiva was œdematous, and the cornea, with the exception of its central part, was hidden by the chemosis. The visible portion of the cornea was quite healthy. There was no watering of the eye, nor photophobia, but slight headache, worse at night, was complained of. No improvement in the eye occurred under scarification, quinine internally, etc.; and the pain in the head increased. The author now looked for signs of syphilis, and found a well marked syphilide on the face, breast, and arms, and enlarged lymphatic glands. Under mixed treatment, the local affections rapidly disappeared, and the patient regained his usual health.—*Lond. Med. Record*, Aug. 15, 1880.

Therapeutics of Strabismus.

M. Boucheron read a paper before the Academy of Medicine in Paris (*Le Progrès Médical*, July 10, 1880) on the therapeutics of strabismus, in regard to the cure of the affection by mydriatics without operation. Basing his argument on the physiological fact that accommodation for short distances is governed by the convergence of the eyes, M. Boucheron proposes to combat the excessive convergence of hypermetropic eyes, and the consequent convergent strabismus, by temporarily suppressing accommodation through paralysis of the mechanism of accommodation with atropin. This plan of treatment was brought before the Academy of Sciences in March, 1879, and the results which have obtained from it may be thus summed up. The *sine quâ non* of success is the intermittent character of the strabismus, since this indicates that the internal recti have not yet undergone that retraction and shortening which is a consequence of their habitually vicious position. The instillation of sulphate of atropin (3 centigrams to 10 grams of distilled water) should be made on the first appearance of the squint.

before there is any alteration in the convergent muscles. Atropin should be dropped into both eyes, to such an extent as is required to paralyze the mechanism of accommodation in each. One or two drops of the solution recommended above dropped in morning and evening will be sufficient to produce the required effect. The atropin should be employed until the squint has disappeared when the child looks closely at anything. This treatment puts a hypermetropic squinting child into the same condition as one who is hypermetropic but does not squint. The length of time during which the atropin must be used, is therefore dependent upon the age of the child when the treatment was commenced, as well as upon the duration of the affection. The strabismus as a rule disappears in two or three weeks, but it exhibits a tendency to recur for several months. In the cases which have been observed the atropin causes no inconvenience, but if it is not well borne, it should be replaced by other mydriatics, as for example, duboisin. In some cases also, myotics, such as eserin, which render accommodation mechanism immovable by causing contraction of the ciliary muscle, may modify the relation which exists between accommodation and convergence to such an extent as to cause cessation of the strabismus. Mydriatics appear, however, to yield more certain results than do myotics. In nine cases of intermittent convergent strabismus occurring in children, in eight this method of treatment gave successful results.—*Practitioner*, Sept. 1880.

A New Method of Iridectomy for Secondary Cataract.

M. Gayet, of Lyons, reminded his hearers at the late meeting of the French Association for the Advancement of Science, that, after extraction of the crystalline lens by operation or lesion, the iris became inflamed, infiltrated with plastic products, and formed as it were a kind of veil, which prevented the rays of light from reaching the retina. Ordinary iridectomy was impossible when the iris was thus indurated. On the other hand, it was known that the iris was not isolated, but belonged to the ciliary system, and was continuous with the processes. At this point it was thin, and tore when touched; but when it had become inflamed, and it adhered frequently to the neighbouring parts, the iris only tore by traction; this became transmitted to the ciliary organ; and it was well known that rough treatment of this region was liable to bring on sympathetic ophthalmia or other serious accidents. These considerations had long been known; and the importance of making an artificial pupil, and the difficulties of accomplishing it, had long been recognized. Cheselden's needle-method gave too small an aperture, and there was danger of wounding the crystalline lens and bringing on a fresh cataract. Von Gräfe's process gave a large opening in the pupil; it was a good plan, but frequently brought on a small hemorrhage, which showed that the ciliary body had been detached. M. Gayet had endeavoured to avoid that inconvenience. The knife being directed obliquely backwards, the blade forwards, he punctured the cornea and the iris; then turned the handle of the knife backwards, and carried it behind the iris. When he reached the other end of the anterior chamber, he directed the handle of the knife backwards, and brought the point outwards. The tension of the iris caused the knife to cut it in proportion as it advanced; the operation was then ended, as soon as the cornea was opened at two points. M. Gayet had performed this operation four times successfully, without difficulty or consecutive accidents.—*British Med. Journal*, Sept. 18, 1880.

Removal of the Nervus Vagus with a Tumour of the Neck.

Prof. Lucke, of Strasburg, relates (*Centralblatt für Chir.*, Sept. 4) the case of a woman, aged twenty-eight, who, having had a cancroid tumour removed from the right submaxillary region in 1878, presented herself in February, 1880, with a relapse, a tumour having formed in the cicatrix, and a large one under the right sterno-cleido-mastoid. On removing the latter, he found it intimately connected with the muscle. The carotid artery was easily separated from it in its whole length, but the jugular vein and nervus vagus were closely united to the tumour. The vein was tied close to the clavicle and above the tumour, and this last was removed with the vein and the nervus vagus attached to it. The bleeding was inconsiderable, and the portion of the nerve measured about twelve centimetres. No remarkable effects were produced on the respiration or pulse at the time of dividing the nerve. The nerve was found to be four times its natural thickness, but no effects were produced on the respiration during the healing of the wound. The patient presented herself in the July following, and manifested only an easily excitable respiration, which in other respects was normal. The right side of the face was in a hypertrophied condition.—*Med. Times and Gaz.*, Oct. 2, 1880.

—

Treatment of Aortic Aneurism by Electro-Puncture.

Dr. Dujardin-Beaumetz records (*Bullet. Gén. de Thérap.*, July 15, 1880), two fresh cases of aneurism of the aorta which he has treated in this way, and in doing so presents an interesting account of his method of employing the electric current for this purpose, and a review of the results of electro-puncture in France generally. He uses only Gaiffe's battery. The needles he recommends have no head, and vary in thickness from five to seven-tenths of a millimetre. The conditions which determine the thickness of the needle to be employed are these: The length of time during which the current is to be passed, and the presence or absence of coagula in the sac. He has noticed that if a current traverses, for ten minutes, a needle less than five-tenths of a millimetre in diameter, there is a risk of breaking the instrument in extraction, and leaving its point in the aneurism. On the other hand, thin needles must be used at first, in order to avoid risk of hemorrhage, if the sac be found to be thin and pulsating strongly; subsequently, however, when repeated *séances* have led to the formation of coagula of greater or less thickness, needles of greater diameter should be introduced. The needles are of soft iron, and are covered with an insulating coating, except at their two ends. The wire connecting the needle with the battery is extremely thin, to permit the needle to oscillate slightly when in position in the sac. The needle is introduced by means of an apparatus designed for this purpose by Gaiffe; this enables the operator to regulate with precision the depth to which the needle is entered, saves much suffering on the part of the patient, and prevents the insulating coating from being rubbed off—an accident which favours caustic action and sloughing on passing the positive current. The needle should also be withdrawn by means of Gaiffe's retractor, an instrument which slowly twists it out. The author thinks the employment of these two little instruments of Gaiffe's of great importance; forceps should never be used instead, as their use involves the putting forth of more force, gives more pain, and is apt to break the needle, which is already thinned and weakened by the action of the current. The negative pole is represented by a large flat plate placed on the thigh; this plate is pierced by a number of holes, and covered with chamois leather; it is moistened when applied, to lessen the smarting which this pole always produces. The strength of the current may be accurately regulated by means of Gaiffe's galvanometer, the needle of which should point to about 54 on the scale. M. D. has been a strong advocate, ever since 1877, of the practice of having only the needles representing the positive pole in the aneurism. With regard to the number of needles to be inserted, and the duration of the current, the author at first followed Ciniselli's practice of introducing four needles, and of passing a positive current through each for ten minutes, at two applications of five minutes each. Now he never uses more than two needles, and most often only one; a longer period of action might lead to deep corrosion of the needle, and cause it to break in extraction. (It is here suggested, as matter for further investigation, whether it might not be of service to pass the current for a longer time, in order to destroy completely that portion of the needle which is left unprotected by the insulating covering. Might not the particles of iron so detached act as centres round which coagulation of the blood in the aneurismal sac would go on? And, further, not only is the oxide of iron formed under these circumstances, but very probably also the chlorides; and these have a coagulant action on the blood.) While the author thus limits the number of needles, and the duration of the current, he advises the more frequent repetition of the operation—every eight to fifteen days; nevertheless, if the intervals are unduly shortened, pain and inflammation result. No anæsthetic, local or general, is used; the ether spray has an unfavorable influence on the coagulation of blood in the sac; chloroform also in such patients, often causes grave syncope, and this occurs the more readily as those suffering from aneurism usually suffer also from aortic insufficiency. Neither ice nor collodion is applied to the puncture holes after extraction of the needles.

M. D. has followed this method of operating for three years, and neither in his own cases, nor in those of his friends, has it been attended by any accident. In one case, however, the passing of the current caused fainting; but this patient had, for years, been subject to such attacks, and they occurred on very slight provocation, such as on being informed of the nature of his disease, and again, when a cardiographic tracing was being taken. The pulse of another patient, a man of excessively nervous temperament, fell markedly when the current was started; though it was thought better to interrupt the operation then, nothing of the kind occurred at subsequent *séances*.

The electric current acts as an irritant to the sac, producing inflammation of its walls, a curative endarteritis, determining the formation of adhesive coagula; it has also a directly coagulant action on the blood. The fact that the clot so produced is an adhesive one is strongly insisted on; the author has never observed anything of the nature of embolism, though he has operated twice on aneurisms of the innominate artery; in the first instance, there was temporary improvement, and in the second, operated on in February, 1879, the improvement then effected still continues. It has, nevertheless, been observed that the clot so formed may split up, and admit of the entrance of blood between its layers, in such a way that just as a complete cure seems to be established the aneurism suddenly shows signs of further extension; this is what occurred in a case recorded by M. Bucquoy.

Positive and lasting cure of aneurism by this means, if an instance of this kind has yet been observed, must of necessity be very rare, as we are able to attack the sac only at very few points on its whole extent—namely, those which in front or behind come into direct contact with the walls of the chest.

Dr. Petit has collected, in the *Dictionnaire Encyclopédique* (Article *Galvano-puncture*) no fewer than 114 cases of thoracic aneurism treated by electro-puncture. In 68 of these decided improvement was obtained, this improvement lasting at least a year in 35 instances, at least two years in 11 cases, and in 3 cases, three four, and five years respectively. Petit's statistics also show the great advantage of operating before the aneurism forms an obvious external swelling; improvement resulted in 73 per cent. of such cases while in those cases in which there was an external tumour, improvement was noted in only 51 per cent.

M. D.'s experience, however, is all in favour of electrolysis in thoracic aneurism; even in instances in which the progress of the disease is not checked, it brings about marked amelioration of pain and of the feeling of throbbing.

In the first of the two new cases here recorded, the patient, a man of 53, had been confined to bed for nine months, suffering intolerable pain, which was kept in check only by subcutaneous injections of morphia, and these had to be increased in number every day; he had also had repeated arterial hæmoptyses. Here relief was so marked that after five *séances* he was able to get up and walk about with ease; pain was lessened to such a degree that he needed only half a syringeful of the morphia solution per day; the patient's general health underwent remarkable improvement; the swelling diminished notably in volume, became harder and firmer, while the movement of expansion of which it was the seat had greatly decreased.

In the second case the patient was robbed of sleep, had incessant cough, intense dyspnœa, great pain, could not rise from bed, while the tumour was increasing daily in size. After five operations he slept comfortably, his pains disappeared, he could rise and walk without difficulty, and was about to set out for the country well satisfied with the progress he had made.

The author concludes with the statement that electro-puncture is a most rational method of treatment for aneurisms of the aorta, and that if it is capable of effecting the cure of the disease only in very exceptional cases, it rarely fails to give substantial relief, even in conditions when every other mode of treatment is powerless, and that without the least danger, if the directions above laid down are scrupulously followed.—*Glasgow Medical Journal*, Sept. 1880.

Results of Treatment of Aneurism of the Aorta by Galvano-Puncture.

M. L. H. Petit, at the late meeting of the French Association for the Advancement of Science, read a paper based upon the study of 114 successful cases of this nature. In 111 cases, continuous currents were employed; in three cases, interrupted currents (Zdekauer, Piedagnel). Of the 114 cases, three were improved; 38 patients died without any notable amelioration; in three cases, there were no results; in four, they were doubtful; 39 patients survived less than a year, though much improved, and 10 from one to two years. The others survived from two to five years. In those patients who had been followed up long enough to have their deaths verified, rupture of the aneurismal sac was noted in about forty. After the disappearance of the immediate symptoms, or even immediately after the application, amelioration had shown itself in a certain number of cases by the diminution of the pains and pulsations, by increase in the consistency of the tumour, and its progressive diminution. This retrograde progress of the disease continued in twenty-four cases after a single application, and lasted from two to seventeen months; in others, three, four, and five applications had to be made; in others, even so many as eleven or even twelve; but that was because the improvement did not last long after each of them. The persons forming this category all died soon after the last application of galvano-puncture. Intrathoracic aneurisms had yielded thirty successful and seven unsuccessful cases. Those which had made their way outwards yielded thirty-six successful and one unsuccessful cases. It was, therefore, evident that, if the proportion of successes were greater when the aneurism was still contained in the thorax, good results might be hoped for in about half of the cases of aneurism of the aorta with external tumour. In 114 cases, 292 applications were made, which were thus classified as to the immediate results: improvement, 186; aggravation, 61; *status quo*, 14; not exactly indicated, 31. Improvement had specially been apparent in the relief of pain, the cessation of paroxysms of angina pectoris, the return of sleep, appetite, etc. Amongst the symptoms by which the aggravation had been characterized, augmentation of the size of the tumour, inflammation in the course of the needles, circumscribed sloughing, somewhat persistent hemorrhages, etc., had been noted. These accidents were observed especially when the needles were put into communication with the negative pole; on the contrary, they were very rare when the positive pole was employed. M. Petit, therefore, concluded, with McCall Anderson, Dujardin-Beaumetz, Teissier, etc., that positive galvano-puncture was the best proceeding hitherto employed.

M. **Potain** believed that the improvements which supervened after the employment of electrolysis in the treatment of aneurism was wrongly attributed to coagulation. In support of this opinion, he quoted the following fact: A man, attacked with an aneurism of the aorta with secondary tumour, was treated by M. Dujardin-Beaumetz. After two or three meetings, the patient was so much relieved, that he was able to leave the hospital; the secondary tumour had considerably diminished. But, after some time, the improvement disappeared, and the patient came back into M. Potain's wards, where he was treated with iodide of potassium and milk-diet. The improvement was as soon marked as after the treatment by electrolysis, and the patient again went home; but, as on the first occasion, the improvement was only temporary. He came back into hospital with pneumonia, of which he died. At the necropsy, a rather thick layer of fibrine was found lining the wall of the aneurism, but no clot. M. Potain likewise believed that it was very fortunate that there should be no clots in cases where the aneurismal sac communicated largely with the aorta, and where the clots might give rise to embolism.

M. **Onimus** maintained that the action of the current was of secondary importance, and that the coagulation of the blood was not the cause of the improvement; besides coagulation, the current exercised over the tissues a vital molecular action which was the true cause of improvement, the chemical action being very feeble. When a clot was found in an aneurism, it was wrong to ascribe it invariably to electrolysis, for clots were found in cases where this plan was not employed.

M. **Heurot**, from a case which came under his notice, maintained that electrolytic action produced clots. In his case, the external tumour became solid and hard, and the pains were remarkably relieved.

M. **Ollier** remarked that statistics had the great disadvantage of not being complete. Successes were published, but not failures. Statistics could not, therefore, be taken as a basis to ascertain how far recovery might be anticipated. On the other hand, M. Ollier did not believe that a complete and permanent cure had been observed. Finally, large clots had been supposed to occur after galvano-puncture, but these clots melted in some way, or they might be displaced by the needles. For these reasons, M. Ollier preferred milk-diet and iodide of potassium. Cases of spontaneous cure of external aneurism had been observed, and there was nothing to prove that the same thing did not occur in the aorta.

M. **Leudet** remarked that all cases of failure had not been made known; for instance, he had operated on two patients whose cases had not been published.

M. **Henrot** pointed out that galvano-puncture was specially a palliative means; and, from this point of view, it was very valuable. It had been specially employed in desperate cases, when rupture of the sac was feared, or existence was unbearable to the patient on account of the acute anguish of dyspnœa, etc., and had always improved the patient's condition.

M. **Petit** replied that, in the majority of the cases collected by him, coagulation of blood in the aneurismal sac, and diminution of the pulsation, *souffle*, etc., had been noted. He was aware that, as a rule, statistics mostly recorded the successes, and that the failures were passed over in silence; but, his statistics being for the greater part compiled from the complete statistics of Ciniselli, Verardini, Duncan, Anderson, Althaus, and Dujardin-Beaumetz, he was scarcely open to that reproach. Complete cure had scarcely been observed in more than two or three cases, but improvement had lasted a long time in a large number of others.

M. **Denucé** had recently treated two cases of aneurism with galvano-puncture. In the first case, there was aneurism of the aorta of two or three years' standing, with a large external secondary tumour; the skin was attenuated, and the pains very acute. A first application of Gaiffe's pile of ten or twelve elements, making use of the positive current applied with three needles during ten minutes, caused immediate cessation of the pains; the tumour became indurated, and the pulsations diminished. After some days, a tendency to dissolution of the clot, and return of the pains and pulsations, were observed. A second application with only two needles had the same result as the first. M. Denucé had made four applications, and the benefit rendered by galvano-puncture to the patient was very considerable. In the second case, an aneurism of the brachio-cephalic artery, as large as a child's fist, and prominent above the clavicle and sternum, was treated in the same way. But, after the first application, there was no induration of the tumour; on the contrary, it increased rapidly, and in five or six days, rupture of the aneurism was apprehended. M. Denucé then tied the common carotid and the subclavian arteries. The tumor then became more tense, and diminished twenty days afterwards. The wounds of the ligatures were cured, but the tumour remained *in statu quo*, and everything pointed to the probability of its speedy rupture.—*British Medical Journal*, Sept. 18, 1880.

—

Multiple Thrombosis and Gangrene.

MM. **Labbé** and **Bruchet** relate (*Union Méd.*, Aug. 26) a case occurring in Prof. Verneuil's service which they regard as probably unique. A miserable-looking little man, aged thirty-six, with no antecedents of syphilis or alcoholism, was admitted complaining of violent pains in all his extremities. These pains especially localized themselves in the right great toe, where there was a little sphacelus, and in the two median fingers, the pulse on both sides being somewhat feeble. Examination detected no visceral alterations nor any cause for what had occurred. Gangrene invaded the foot at five or six intervals, being accompanied by the most dreadful pain. Amputation of the leg was performed by means of the thermo-cautery, with antiseptic precautions, not a drop of blood being lost. Immediate relief followed. There was no fever, the general condition was improving, and the appetite had returned. On the eighth day there was a slight hæmoptysis; and next day there were signs of internal hemorrhage with sphacelus of the flaps, and death took place. The examination of the amputated limb had exhibited thrombosis of the two tibials, and the same lesions were now found in the tibials of the sound side, and in the two ulnars, and in one of the two radials, although no symptoms had announced these lesions. Not less than a litre of blood was found in the stomach, and near the small curvature were two round ulcers, one of which had opened into an arteriole of about two millimetres in diameter. No other change was observed except slight atheroma of the aorta. The arteries affected with thrombosis presented endarteritis, which extended to the middle coat inclusively. Virchow has stated that simple ulcer of the stomach results from limited arteritis, and this case confirms his opinion.—*Med. Times and Gaz.*, Sept. 4, 1880.

Case of Laparotomy for a Singular Cause.

A man, three weeks before being brought to the Vienna General Hospital, had introduced a varnishing brush, seven inches long, into the rectum in order to relieve constipation. When the brush had entered deeply, the handle slipped from his hand, and he continued for three weeks to keep the body in the abdomen, in the hope that it would be discharged at stool. Violent pains then coming on, he was brought to the hospital, and a diffused peritonitis was found to exist. An exploration of the rectum by Simon's method was practised without the body being detected; and, as the patient was quite positive that the brush was still in the abdomen, Hofrath Prof. BILLROTH performed laparotomy. It was found that the brush had penetrated as far as the sigmoid flexure, about twenty-five centimetres distant from the anus, and there had penetrated the intestinal canal, producing a diffused peritonitis. The man died six hours after the operation.—*Allg. Wien. Med. Zeit.*, August 17. [In the same journal for August 31 is related by Dr. WALSER, of Graz, a very similar case, which, however, having been seen much earlier, had a more fortunate termination. A man, three days before his admission to the hospital, had passed the handle of a hammer, twenty-five centimetres in length and two and a half in breadth, into the rectum in order to arrest a diarrhœa, and while doing so it slipped from his hand and disappeared. The abdomen was moderately distended and only slightly sensitive; and, on making firm pressure over the umbilicus, a hard, movable body could be felt, having its end exactly in the middle of the epigastrium. It could not be followed downwards, but seemed to have entered the pelvis. The general state of the patient was satisfactory, but he resisted exploration by the rectum so much that he was put under anæsthetics. Although the body could not be felt in the rectum, by pressure and manipulation of the upper end, Dr. Walser was at last able to get hold of it with a lithotomy forceps and slowly remove it.]—*Med. Times and Gazette*, Sept. 25, 1880.

Operations for Umbilical Hernia.

In a communication to the Société de Médecine (*L'Union Méd.*, Sept. 5), M. POLAILLON related two cases of strangulated umbilical hernia occurring in women, forty-one and forty-four years of age, both of whom recovered promptly after operation. He observed that these facts, taken with others which have been published, are of interest, as showing that umbilical hernia, when small or of medium size, may be operated upon with pretty much the same chances of success as in other forms of hernia. The excessive mortality which had attended the operation, and which led many surgeons to proscribe it altogether, was observed before antiseptic treatment was introduced, and was due to suppurative peritonitis being so frequently set up. Under the antiseptic method immediate union usually takes place, and this danger is rendered very slight.—*Med. Times and Gazette*, Sept. 18, 1880.

On the Progress in the Treatment of Stricture of the Urethra.

At the late meeting of the British Medical Association Sir HENRY THOMPSON introduced in the Surgical Section a discussion on the treatment of stricture of the urethra with the following interesting and instructive remarks:—

The most important changes in relation to the treatment of stricture of the urethra, during the last thirty years, in this country may, I think, be classified under five heads.

1. A general recognition of the principle, that a delicate and gentle manipulation of any instruments in the urethra is alone trustworthy or permissible, in the

place of that which was formerly greatly prevalent—viz., that urethral obstruction might often be overcome mainly by force.

2. The substitution of very pliable and taper instruments for silver and stiff gum-elastic instruments in much of the treatment, both in ordinary and in continuous dilatation.

3. A more general acceptance of the doctrine, that—given time, patience, and gentle handling—very few strictures should be met with which cannot be fairly and successfully traversed by an instrument passed through them into the bladder. At the same time, an undoubted improvement is to be noted in the mode of operating for those exceptional cases in which the surgeon fails to accomplish that object.

4. A more general acceptance of the doctrine, that dilatation of the urethra, whether with or without incision, may be carried with advantage to a somewhat higher degree than had for some time previously been regarded as desirable.

5. The substitution of internal urethrotomy in some form for the application of caustics, and for external urethrotomy on a guide.

All these may, I think, be accepted, and will be generally accepted, as illustrations of advance in the treatment of stricture.

I propose to make a remark or two on each of the topics named, at the same time venturing to indicate anything which may appear to me to be a sign of retrograde movement at any point.

I need say little on the first subject—viz., the substitution of gentleness and more careful modes of manipulation for those which were previously in vogue. Men of the present generation, however, scarcely know how rude, and, in some hands, almost barbarous, was the method of handling formerly employed in the treatment of urethral disease. The term "forcing a stricture" was then, as it had long been, an accepted surgical term both here and abroad, and denoted simply the systematic application of violence to an organic obstruction—the result of which, in nine cases out of ten, was, and could only be, the laceration of the canal and the making of a false passage. I suppose I am right in saying that such a proceeding is no longer a surgical one; and, if ever adopted, is intended to be an exceptional occurrence, and not within the limits of the rules of our art. If there was one thing more than another in the treatment of stricture which, at an early date, appeared to me unwarrantable, not to say shocking, it was the sight of a surgeon, firmly grasping a solid instrument and pressing its points with rigid arm against an urethral obstruction until something gave way, and the point was made to advance—somewhere. From the earliest time to the present, I have invariably taught, not merely that a narrow stricture can only be traversed by gentle means, but that nothing prevents success so much as a deviation from this rule; and I believe that the constant advocacy of it has not been without its influence in suppressing the dangerous practice which formerly was but too common.

The substitution of modern flexible instruments, chiefly of French origin, for the silver catheters almost invariably used thirty years ago, when the old wax or plaster bougies had fallen, somewhat undeservedly, perhaps, into disrepute, has been an advance of enormous importance. I first learned the value of flexible instruments many years ago in Paris, and have used them ever since, and still desire to speak in high terms of their practical utility in most of the varied forms and kinds in which they are presented. To a certain, although limited, extent, some of them have aided us to achieve that very considerable advance in the treatment of stricture which was set on foot by the late Professor Syme, and consisted in the doctrine (first distinctly taught and illustrated by him), that impermeable stricture is a condition of extreme rarity. In other words, he proved that almost any stricture, however narrow, if urine passes outwardly through it, is permeable also to instruments in the hands of a careful, patient, and practised surgeon—provided only there is no crisis of actual retention present demanding immediate relief. The gain accruing to the patient through this doctrine has been very great; since, thirty years ago, a dissection through the perineum for so-called "impermeable stricture" was a comparatively common operation in our hospitals; and one, moreover, which was frequently fatal. Very rarely, indeed, ought such a proceeding to be heard of now, since, with time and patience, a fine instrument can almost invariably be carried safely through any stricture into the bladder.

But these instruments are invaluable also in prosecuting the ordinary treatment known as "dilatation." Notwithstanding the small value set upon this method by some surgeons, who profess to regard it as scarcely worth the name of treatment, and desire to substitute urethrotomy in almost all cases of stricture, whether recent or confirmed, I see no reason whatever for discarding it. If the cutting operation necessarily conferred a cure, in the sense of preventing return of the disease, even in a bare majority of cases, the propriety of employing dilatation might perhaps be called in question. This point will be considered hereafter; meantime, there can be no doubt that such complete relief is afforded and on terms which are easy, by the use of simple flexible bougies, or by the same supplied with lead cores, and, lastly, by well-polished tapering metal sounds, that I believe it to be in the patient's interest to employ dilatation only so long as it is quite efficient; and then, as soon as it ceases to be so, and mostly not until then, to adopt other methods of a more serious kind.

To revert for a moment to the occasional existence of an "impermeable stricture," which has just been referred to, it may be briefly said that when, as sometimes happens, the surgeon fails, after adequate trials, to pass any instrument, however small, through a narrow or tortuous stricture, the method known as "perineal section" sometimes proves a valuable resource. Like other proceedings, it has been rendered more easy and efficient, and is a far safer operation than that which was done fifty years ago. Since that time, various little improvements have been added to the details of the performance, so as to facilitate the finding of the narrowed passage.

The "calibre" or "diameter" of the urethra, or the amount of its dilatability, is a subject which has come again to the front during the last few years: this time, from attention paid to the subject in America. This is one of those points relative to which our figure of the pendulum is in some measure applicable. It has always been a subject affording matter for discussion throughout the history of urethral surgery, relative to which, had we time, I could give you some curious illustrations. The different measurements made by anatomists at different epochs —and their name is legion—are remarkable chiefly for their diversity; and the rules of practice pursued by different surgeons have similarly varied. This is a fact which need not excite surprise, considering the complex nature of the passage, the relations of which have been so largely studied. The question is one of sufficient importance to be worth considering, perhaps, more closely. A good deal of the apparent discrepancy in the measurements, in the use of terms, and consequently in the practice of different surgeons, is due, in my opinion, to a certain failure among many to recognize what are the natural physical conditions of the passage in question. We hear of its size, of its diameter, of its calibre, as if the urethra were a tube of constant capacity—as if it resembled an artery, a bronchial tube, or an intestine. But in fact, the urethra has no constant quality comparable with that which we call "size" in any sense in which that term applies to the passages just mentioned. Indeed, the urethra has no "size" or "calibre" when it is not used as a canal; and it is only thus used during a few minutes, one might rather say seconds, during the twenty-four hours, and also when artificially opened by the passing of a foreign body into it. It is simply a long chink, the sides of which are maintained in close contact by organic muscles, and traversing a mass of complex structures, which, like itself, are susceptible of great physical changes under different circumstances. Second to its natural contractility, the most distinguishing mechanical quality of this closely shut passage is its dilatability—a still undetermined, and, I may add, an undeterminable, quality; for its dilatability naturally varies greatly in different parts of its course, in consequence of the variety in the nature of the surrounding structures; while its own delicate walls and subjacent tissues are almost indefinitely extensible under the influence of continued pressure.

During the first third of the present century, there was a strong tendency, both here and in France, to regard the urethra as a passage of greater size than the surgeons of the preceding epoch had assigned to it, and to use larger instruments in the dilatation of stricture. Boyer advocated them, and, later, Mayor of Lausanne employed them, sometimes with much force. In this country, Pearson, who had a large experience, made a point of carrying dilatation as a cure for strictures to Nos. 18 and 20, English scale, equivalent to about 28 to 32 of the French scale. One of his instruments has long been in my possession, and is here for your inspection. A good deal of mischief followed what may have been the indiscriminate use of these large bougies; hence a reaction took place, and smaller sizes were adopted, with less beneficial influence, perhaps, upon the stricture itself, but also with less evil on the constitution of the patient. Within the last few years, Dr. Otis, of New York, has revived the theory of "the large diameter of the urethra," and has advocated larger instruments; besides recognizing as examples of organic stricture very slight deviations from what he conceives to be the normal "calibre," or what I should regard as the possible extent of dilatability possessed by the passage. I have no intention of formally examining the views which he has enunciated relative to this matter, having no allotted time or space in this paper for the purpose. But I will venture to say, in connection with this subject, that we, on this side, may perhaps have erred somewhat during the period of reaction referred to, in not sufficiently availing ourselves, especially in the practice of lithotrity, of the large degree of dilatability which the urethra undoubtedly possesses; and that we owe to our American brethren an advantage which the latest assertion of that fact has pointed out to us. And I desire hereby to record my sense of the value of that lesson by assuring them how gratefully I receive and profit by it. But I cannot say thus much without also saying, in the same breath, that it is a very easy thing to damage irreparably some individuals by overdistending the urethra, and that such damage I have of late witnessed in several instances. I must oppose, also, another doctrine which is associated with the proceeding, viz., that stricture of the urethra is permanently cured by complete division of all the diseased tissues affecting the passage. I have seen too many examples of return of narrowing in cases thus operated on, to admit that at present we possess any certainty of being able so to act on a confirmed organic stricture, as to insure its non-appearance in after-life. Further, I have carefully followed many of Syme's cases of external division in his and in my own hands, where the diseased structures constituting stricture have been entirely divided, and in a way more certainly complete than any internal urethrotomy can offer; and am compelled to avow that, in very few instances indeed, has the thus divided stricture not reasserted itself after the lapse of time. Nevertheless, it is an important truth that, when any portion of the stricture escapes division, the narrowing speedily returns.

For that operation, I have myself substituted internal urethrotomy in the treatment of obstinate cases, during a period of now considerably more than twenty years, having ceased to perform Syme's operation, as a rule, in 1857. Since that date, I have performed the internal operation at University College Hospital and elsewhere some hundreds of times. My experience leads me to regard it as a far safer proceeding than Syme's in relation to life, and one which is quite as efficient in relation to the general results.

But, at the date named (1857), internal urethrotomy was rarely, if ever, employed in this country; the method best known here, viz., that advocated by Stafford, had lapsed through its inadequacy to render any important service, and dilatation and caustics constituted the treatment for the great majority of cases. Like many of my brethren, therefore, I tested other proposals which appeared soon afterwards, such as by splitting the stricture, which attained a considerable popularity for a time; overdistension, etc. Like others, too, I believe that there are good grounds for the conclusion that, for those examples of the disease which are so confirmed as to defy dilatation, those methods are inferior in permanency of effect to a well performed, that is, to a complete, division by internal urethrotomy.

Nevertheless, regarding the many methods of performing internal urethrotomy which have been proposed and practised, I doubt whether it is possible for any one to pronounce which is absolutely the best. In every one, the object is, or ought to be, the same, viz., the complete division of the morbid tissue; but varied mechanical means of accomplishing this are originated by different minds, and different modes suit the hands of different surgeons. Each one probably prefers to accomplish the object with the instrument with which he is most familiar, and that method will generally be the most efficient in his hands. At the same time, many of the modes employed to accomplish internal urethrotomy will not insure the complete division of the strictured portions of the urethra, and such methods must be regarded as defective.

The principles which govern a sound procedure are more essential points for the surgeon to discover and to teach, than a consideration of small details. These principles may be briefly stated, I think, as follows:—

1. The necessity for a physical examination before operating, to detect and estimate the narrowed portions of the urethra. This is best accomplished, in my opinion, by means of a series of metal bulbs on slender stems, taking care not to regard as diseased changes those points at which the urethra itself is naturally only slightly dilatable. These bulbous exploring sounds I have invariably used, advocating them as essential to diagnosis in my first work, twenty-six years ago; and I still prefer them to any other, as safer, less irritating, and not less efficient, than more complex instruments which have been devised.

2. The necessity for accomplishing a complete division of all the morbid tissue constituting the stricture, by an incision carried through it; no matter what part of the urethra, or how much of it, is involved in the disease. As a general rule, this is, I think, most efficiently completed by a slender blade, carried beyond the stricture, and made to cut from within outwards; this latter proviso being, however, an open question. The important point, however, is, that any alleviation of the patient's condition attained by operation will be transitory if any part of the narrowing be left undivided.

3. I regard it as essential, after such division, to place at once a full-sized catheter for some hours in the bladder, to insure a free outlet for the urine, and prevent all possibility of extravasation of urine into and through the incisions thus made.

4. The necessity for passing full-sized bougies subsequently, at occasional in-

tervals, in order to effect free distension of the walls of the urethra, which lie in almost constant apposition, and so to prevent reunion of divided surfaces by the first intention.

The foregoing may, I believe, be held to embody those general principles which most experienced surgeons at the present day agree—with a few dissentients, I am aware—ought to guide us in practice. That there are different modes of carrying them out, is, as I have before intimated, a matter no less of notoriety than of necessity, as inherent in the nature of things. Such a circumstance may be regarded as one fraught with some advantage for us here, in providing scope for discussion, and so eliciting a comparison of ideas and methods among the many experienced observers who honour the Section with their presence this day. I shall, therefore, very briefly offer my own views as to the best mode which a long familiarity with the operation in practice has led me to adopt.

In respect of the instrument to be employed, I unhesitatingly avow a preference for one which, in principle of construction, resembles a slender knife with a long handle, in order that it may act completely in obedience to the impetus given to it by the hand. Concealed within a bulb at the end of the instrument is the blade; so that, before this is unsheathed, the urethrotome itself is an efficient bulbous-ended explorer (like those already employed in the previous exploration), and is used as such to identify the stricture again at the very moment of operating. With such an instrument, the incision is directed solely by intelligence, and is limited or extended according to the sensations experienced by the operator's hand, of resistance or the reverse; just as happens in the analogous instance of division of tissues which are not visible, in the case of contracted tendon in club-foot.

To my mind, having had some little experience of the last-named proceeding many years ago, when surgeon to the Marylebone Infirmary, the two operations much resemble each other, and alike require a skilled and unrestricted hand to accomplish a satisfactory division of the constricting tissues; the right amount, neither too little nor too much.

All urethrotomes in which the blade can only move in a grooved director, and this is undoubtedly the most common mode of constructing them, produce a more or less uniform mechanical result, and are incapable of effecting any variation in depth and extent of incision, often necessary to accomplish adequate division in the varying conditions requiring operation. This is what I am compelled to regard as a serious defect, and explains my preference for the bulbous-ended instrument described. It is right to say, however, that the following objection to the latter is sometimes raised, viz., that very few strictures requiring operation are sufficiently narrow to permit the introduction through them of an urethrotome, the bulb of which is equal to No. 5 or 6 of the English scale. That may be quite true; but I have never seen a case of stricture, however obstinate or narrow, which could not be temporarily brought to the size required by tying in a slender gum-elastic catheter; and I think the advantage of operating in the manner described well worth the delay of a day or two devoted to such preparation of the urethra. Still, I am quite ready to concede that an instrument which cuts by means of a blade advancing from without inwards, on a guide previously passed, may be a safer one in some hands, especially if they be not thoroughly practised in traversing the urethra. My experience of internal urethrotomy, which has been thus conducted throughout, that is, on the same principle and with the same instruments, has been from the first exceedingly satisfactory. The operation itself is fraught with very little risk; the durability of the relief afforded is the chief question to ascertain. The last twenty years have enabled me to watch the history and course of a good many cases; and, speaking in general terms, I may say that the first three or four years after the proceeding, often more, are very comfortable for the patient; after which, at earlier or later dates, say from four to seven years afterwards, he often finds himself reluctantly compelled to retreat a number or two in the size of the bougie, which he has been accustomed to pass once or twice a month. Instead of 11 to 13, English scale, he must be content with 9 or 10, or less; but he has no symptoms to complain of. At an interval, varying in different cases from seven to twelve years, the condition in some cases becomes troublesome, and the patient finds No. 7, 6, or 5 perhaps, frequently necessary, and also that some of the old symptoms have returned. In such circumstances, I do not hesitate to advise another operation, and have occasionally performed it a second time. It so happens that I did this for one of my medical brethren only last week, having previously employed the same proceeding in 1867, thirteen years ago. I passed a No. 17 English, about 28 French, with ease, immediately after the incisions, and he is now doing admirably. In one case only, I have done the operation three times for the same patient. There is no reason why it should not be repeated, if necessary, just as we crush a second or a third calculus which may be formed after the first. In the case last referred to, the best result followed the third operation, and occasional dilatation has been quite sufficient to maintain a highly satisfactory state of the urethra ever since, although the date of that operation is at least eight years ago. I am very certain that the plan I have followed is one of great value for cases in which dilatation does not afford adequate relief; and I certainly think we are more prone to err in withholding the operation than by recommending it too generally. Inadequate relief to the stricture involves irretrievable mischief to the ureters and kidneys; and many a life has been sacrificed to persistence in painful and inefficient attempts to dilate, which might have been saved by free division of the stricture or strictures. The formation of a free passage for the urine is the necessary safeguard for the secreting organs, and there should be no loss of time in accomplishing it by internal urethrotomy, so soon as the stricture is no longer readily amenable to the action of dilatation. But when the operation is adopted, nothing less than a free and complete division of all the obstructing tissues should satisfy the operator. It cannot be too often repeated that on this depends the success of the operation.

The great desideratum of the present time unquestionably is the discovery of a mode of treatment which shall permanently restore to the strictured passage its original dilatability. I cannot say that a thoughtful consideration of the pathological condition which constitutes organic stricture, emboldens me to hope that such a result can be insured by the application of any principles of action at present known to us. If this be so, a large and important field for labour and for speculative inquiry is open in this direction. May it fall to the lot of some abler successor to this office of mine to-day, to record the accomplishment of this great achievement before another thirty years have expired.—*British Med. Journal*, Aug. 28, 1880.

Fat-Embolism in Fractures.

The subject of fatty embolism in cases of fracture, though it has attracted considerable attention in Europe, has not been much noticed in this country, therefore the particulars of the following case reported by Mr. F. A. SOUTHAM, Medical and Surgical Registrar, Manchester Royal Infirmary (*Lancet*, July 10, 1880), in which this condition was found to be present after death, will be read with interest.

A man, aged forty years, was admitted into the Manchester Royal Infirmary about 11 A. M. on February 27th, suffering from a severe compound comminuted fracture of the bones of both legs about their lower third, caused by a railway wagon passing over them. Amputation of both legs below the knee was performed antiseptically immediately after admission by Mr. Heath. The patient bore the operation very well, and was kept under the influence of opium afterwards. The evening temperature registered 101.2°. He passed a good night and expressed himself as feeling very comfortable the following morning. Temperature 103°; pulse 132; his general condition appearing altogether very satisfactory considering the severe injuries he had received. About 3 P.M., however, the same afternoon, a sudden change was observed; he became very restless and excited, his countenance of a somewhat dusky hue, with increased frequency of the pulse and respiration; no rigors nor marked dyspnœa were observed; later on he became delirious and his condition was quite hopeless. At 9 P.M. the temperature was 105°, the pulse too quick and weak to be counted. There was slight discoloration of the integuments of the stumps discernible above the dressings, and a faint odour was perceptible, showing that putrefactive changes had been set up in spite of the antiseptic measures employed in the operation. At 10 P.M. death took place. (Strange to say, both the patient's arms had been amputated above the elbows about nine years previously for injuries of a similar character.) A post-mortem examination was made by Dr. Bradshaw, pathologist to the hospital, but no morbid changes of any importance were perceptible to the naked eye. As from the nature of the injuries it was thought not improbable that fatty embolism of the lungs might be present, a portion of those organs was kept for microscopic examination.

Sections of the lung were afterwards made by Dr. Bradshaw, and on staining them with a solution of osmic acid, the presence of fatty matter in the capillaries and minute arteries was at once detected by him. It presented itself as minute globules and irregular masses of various sizes and shapes completely blocking up the vessels. Unfortunately none of the other organs were kept for microscopic examination.

In this case it is difficult to say whether the fatal result must be attributed to the plugging of the minute vessels of the lungs by particles of fat, or whether it was due to a condition of acute septicæmia which so often suddenly sets in about the middle or end of the second day after the receipt of a severe injury, and which usually causes death in the course of a few hours. The symptoms of this acute form of blood-poisoning are described by Billroth as "collapse with cyanosis" suddenly setting in. "The patients appear as if suddenly poisoned after having perhaps felt quite well during the first twenty-four hours after the operation." In this case death was at first attributed to this latter condition, and the rapid rise of temperature to 105°, along with the state of both stumps, would certainly be strong arguments in favor of it. On the other hand, the fatal result may have been due to the plugging of the vessels of the lungs, for the clinical symptoms of fatty embolism, as hitherto described—viz., collapse, more or less sudden, accompanied by the general signs of shock, though usually coming on shortly after the receipt of the injury, may be delayed for twenty-four hours or even two or three days, the patient in the mean time appearing comparatively well. The taking up of the fat by the open vessels from the medulla of the bone begins immediately after the receipt of the injury, and where an interval of time elapses before the symptoms of pulmonary embolism suddenly appear, may it not be explained on the supposition that the fatty matter, temporarily arrested or stranded in the vessels in the neighbourhood of the wound, is, after a time, when the patient has recovered from the shock of the injury, and when reaction has set in, suddenly carried on with the blood-stream under the influence of the renewed circulation, until it is arrested in the vessels of the lungs?

Fatty embolism of the lungs, though most commonly observed in compound, has also been found in cases of simple fracture. A very interesting case was reported by Dr. Hamilton, of Edinburgh (*Brit. Med. Journ.*, October, 1877), where this condition was found in a patient after rupture of a fatty liver, and it is not at all improbable that it is present to a greater or less degree when life is suddenly terminated by severe injuries, and especially in those cases attended by lesions of the osseous system.

In a paper published by Prof. Sanders and Dr. Hamilton, which appeared in the *Edinburgh Medical Journal* last year, particulars are given of a case of diabetic coma, in which, after death, fatty embolism of the lungs and also of the kidneys was observed. In the former organs, "not only were the small vessels plugged with the oily embola, but in the larger and middle-sized arteries the oil-globules spread themselves out on the wall of the vessels and adhered to it." A peculiar condition of the blood was observed, and this has also been found to exist in other cases of a similar nature. It presented the characteristic odour of acetone, and on standing a milk-white stratum collected on its upper surface, which on microscopic examination was found to consist of a fine chyle-like emulsion of oil, the globules being minutely divided.

Though numerous cases have been described on the Continent, these are, as far as I am aware, the only two hitherto recorded in this country in which on post-mortem examination fat-embolism of the lungs has been found to exist.

The most recent researches on the subject of fat-embolism are, I believe, those of Wiener (*Arch. fur Experim. Path.*, vol. xi.), who made a number of experiments on different animals (dogs, rabbits, frogs), injecting pure olive oil into the serous cavities, veins, and subcutaneous tissue.

In a first series of experiments, he found that when oil was injected into the pleura or peritoneal cavity, extensive fat-embolism was found in the capillaries of the lungs in the course of a few hours. When the oil was injected into the subcutaneous tissue the pulmonary embolism, which was much more limited, did not appear until the third or fourth day; this he proved was due to the intervention of the lymphatic glands, which retained and probably at the same time partly emulsified it. The conclusion he draws from these results is that the fatty matter can be taken up not only by the veins (as was formerly supposed), but also by the lymphatics, even when they are intact, and that the intervention of lymphatic glands does not, as has been suggested, altogether prevent fat-embolism in the lungs.

In a second series of experiments Wiener found that changes in the lungs, consisting of ecchymoses and pulmonary œdema, due to the presence of fat-emboli, were only present when very extensive fat-embolism existed; hence he infers that as a rule fat-embolism is perfectly harmless and does not give rise to the symptoms of dyspnœa, convulsions, shock, etc., which have been observed in man in cases of fat-embolism occurring after fractures. This view is supported by the fact that many of the animals experimented upon remained perfectly well, and yet when killed fifteen to twenty days after the injection, showed extensive fat-embolism of the lungs.

In a further series of experiments with respect to the ultimate destruction of the fatty emboli, he found that this condition was present in many organs, but especially in the brain and kidneys; few, if any, emboli were found in the liver, as in this organ the fatty matter seems to pass very readily through the walls of the capillaries, becoming deposited in the form of large fat-drops in the hepatic cells. In the kidneys the fat is found in the glomeruli, in the vasa afferentia, and in the tubuli themselves; from these facts, coupled with the appearance of large masses of fat in the urine soon after the injection, Wiener infers that the greater portion of the fat injected is carried with the blood into the kidneys, where it is eliminated in the glomeruli, and passes away with the urine. At the same time no doubt another portion by becoming emulsified is taken up by the lymphatics. Finally, he found that in moderately strong dogs all the fat injected appeared to become eliminated in from three to four weeks.

As illustrative of the facts observed by Wiener with respect to the part played by the liver in cases of fat-embolism, I may refer to a case of diabetic coma which was a short time ago in the Manchester Infirmary, under the care of Dr. Dreschfeld, and in which, both before and after death, the blood was found to contain large quantities of fatty matter. On post-mortem examination, Dr. Dreschfeld found no evidence of fat-embolism in the lungs nor in the liver, but in the latter organ he observed extensive and well-marked fatty infiltration of the hepatic cells.

As a complication of simple fractures, fat-embolism must not be confounded with those cases of venous thrombosis starting from the neighbourhood of the injury, and where death sometimes suddenly results from detachment of a portion of the clot and its lodgment in the pulmonary artery or one of its large branches. In the *Lancet* of March 1, 1879, I published particulars of two cases of this fortunately very rare complication of simple fractures of the lower extremity, where, on post-mortem examination, embolism of the pulmonary artery was found, causing sudden death.

The whole question of fatty embolism is still involved in much obscurity, and from the importance it possesses both in its clinical and its pathological bearings, it is one well worthy of further investigation.

Treatment of Sprains.

MR. R. DACRE FOX, Surgeon to the Manchester Southern Hospital, in a communication to the *British Medical Journal*, Sept. 25, 1880, makes the following interesting observations on the treatment of sprains:—

The frequency with which sprains occur in general practice, and the somewhat unsatisfactory results of the treatment ordinarily adopted, induce me to bring forward a method that I have used in a great many cases with considerable success. Sprains may be broadly divided into two kinds, mild and severe; the former consisting merely of a temporary overdistension of the parts around a joint, which rest and anodyne applications usually soon cure; the latter involving, as I believe, much more serious pathological results, which the following plan is specially contrived to obviate.

The effects of a severe sprain are, that the fibrous ligaments controlling the movements of the joint and binding the tendons in their grooves become overstretched, swollen, and softened; the cellular tissue about the ligaments and in the tendon-grooves becomes œdematous; and plastic material is exuded; while, as a consequence of these changes, the tendons are displaced in their beds. If this condition be not actively treated, it may, and often does, lead to continued lameness, due, in all probability, partly to a diminution in the calibre of the tendon-groove, with impaired muscular action, and partly to the torn ligaments and bruised cellular tissue having undergone changes which render them incapable of adapting themselves to the movements of the joint, which are consequently impeded. I believe this result may be prevented by the application of firm direct equal pressure, applied manually at first, and kept up and controlled by pads placed in the line of the tendons, and kept in position by properly-shaped plasters and bandages, and sometimes by splints. This pressure helps to disperse the œdema, to replace the tendon in its normal position, to hasten the absorption of any plastic exudation, and thus to prevent diminution in the calibre of the tendon-groove. I cannot say this is a novel method of treatment; but I think it is one not usually practised, partly because it entails the expenditure of much time and trouble, and partly, I feel sure, because there is and has been a tendency to underestimate the inconvenience and distress arising from a badly sprained joint.

The common practice, in treating a sprain, is to put on a bandage, telling the patient to take it off if the joint becomes painful, and to substitute warm-water fomentations. When the swelling has subsided, if the injury be not so slight as to be already cured, a liniment or the application of iodine is generally ordered. Very frequently the tight bandage causes inflammation, while the rubbing and painting are practically useless. There are numbers of cases of slight sprain, indeed, which will get well with comparatively little treatment or none at all; but in that more severe form where, after an inflammatory or at least exceedingly hyperæmic stage, swelling takes place with the results I have described, the application of these remedies does not prevent the joint from being left rigid, painful, and unfit for use for a very long period. Now it is, as I have said, in preventing all this, that the plan of treatment by direct, equal, and continuous pressure will be found exceedingly valuable; for, where it has been properly carried out, I have always found that the joint returns quickly to its normal condition—pain being speedily relieved, and rigidity prevented. The treatment may be divided into two stages; the first lasting from a day to a week or longer, during which the treatment has to be directed to averting inflammation by rest, warm applications, anodyne lotions, etc.; the second commencing when the joint has become cold, swollen, and painful on movement—in fact, when the injury has assumed a more or less chronic character. It is during this second period that I believe the active treatment I advocate ought to be employed. It is important not to commence this until the surface-heat is normal; for undoubtedly, when any tendency to inflammation exists in the tendon-sheath, pressure aggravates it, and I have known it to lead to untoward results.

It is of course impossible, within the limits of this paper, to describe the special adaptation of this method to each joint; but I will take as an illustration the ankle. If a wire be passed round the joint so as to impinge on the two malleoli and the tendo Achillis, it will define three or four well-marked hollows: one on each side of the tendo Achillis behind each malleolus, one in front of the fibula, with a fourth shallower one in front of the tibia. When the ankle is severely sprained these fossæ become obliterated, and are filled up with effusion, overstretched ligaments, and displaced tendons.

Observation has led me to believe that there are very few sprained ankles in which muscular displacement to some degree does not take place. It most commonly occurs in front of the outer malleolus, involving the outer part of the annular ligament, the extensor longus digitorum, and the anterior fasciculus of the external lateral ligament; next, perhaps, the posterior peroneo-tarsal ligament and structures behind the external malleolus. Cases of similar overstretching and displacement on the inner side of the ankle are happily rare; but in gravity they bear much the same relation to the former as a Pott's dislocation does to a simple fractured fibula. I will assume an ankle-joint has sustained a severe sprain all round, and has arrived at the chronic stage: modifications of the treatment of such a case will meet all that are likely to occur. To carry out the first principles of treatment by direct, *equal*, and continuous pressure, it is clear the fossæ mentioned above must be filled, or rather their sites covered by pads so as to cause the retaining plasters, bandages, and splints to exercise equal pressure everywhere. By making pressure with the thumb from below upwards in the line of the fossæ, a good deal of the œdema may be squeezed away and the displaced tendons in some degree restored. I make, as a rule, five pads (of tow and lint or leather): two about four inches long by one inch wide (one a little shorter than the other, so as to be better adapted to the curve extending upwards from the dorsum of the foot to the crest of the tibia); another shorter, broader, and thinner, to place over the tibialis anticus and extensor proprius pollicis; and two, three, or four inches long, and bolster-shaped, to fill in the posterior fossæ on each side of the tendo Achillis. It is often advisable, in old-standing cases, to supplement the pads by strips of plaster to insure firmer pressure. Both pads and strips of plaster should be made exactly to fit, as, if too large, they are useless, from the pressure being too diffused; and, if too small, they exercise too little pressure. A moment's consideration will render this obvious. If too large a pad, for instance, be placed over the outer postmalleolar fossa, its edges rest on the tendo Achillis and outer malleolus like the piers of an arch, leaving the fossa itself untouched. To keep these pads in their place, I use a long extended half-moon-shaped piece of plaster (emplastrum saponis spread on leather), long enough for the ends to overlap in front when the heel is placed in the centre, and a narrow oblong piece above this, placed round the lower part of the leg, to cover the upper part of the pads. The handiest way to apply the pads is to place an India-rubber band above the ankle, to slip the pads under it, and then, planting the heel in the centre of the curved plaster, to bring the two ends across the front of the joint so as to overlap. The pads having been secured in position, the elastic ring is to be cut, and the oblong piece of plaster put on so as to encircle their upper ends; lastly, the whole ankle is to be firmly bandaged. Amongst the working classes, or in the case of an uncontrollable patient, it is advisable to apply two thin splints over the anterior pads, keeping them in position by a long strip of adhesive plaster. Where there is much superficial ecchymosis, where there are bullæ, or where there is unhealthy-looking skin, instead of using soap-plaster, the pads may be kept in position and pressure maintained by a piece of lint on which ointment has been spread. Calamine ointment made stiffly is clean, and not uncomfortably greasy. If, as occasionally happens, even this should cause irritation, warm wet lint, covered by oiled silk, may be advantageously used over the pads, and secured by a firm bandage; but neither of these applications can compare in efficiency with the soap-plaster spread on leather.

Midwifery and Gynæcology.

Sterility; Excision of Anomalous Membrane; Conception.

Dr. E. D. Mapother reports (*British Med. Journal*, Sept. 4, 1880) the following interesting case: In October, 1878, a lady, aged 28, and married seven years, consulted Dr. Kidd and Dr. Mapother concerning sterility. She was a person of great beauty and large frame, and with full breasts. A symmetrical and evidently congenital membrane was found to cross the vagina at right angles about three inches beyond the myrtiform caruncles. There was a central circular aperture, about two lines in diameter, and a sound passed through it found a cavity about an inch long before the cervix. The front of the membrane being smooth and convex might be mistaken for this part, save for the very different shape of the opening. At its circumference posteriorly it was thick enough to suggest the possibility of there being a peritoneal inflexion. There was no other abnormality, and the patient and her husband had been quite unaware of any. The possible risk above named having been explained, Dr. Kidd wholly excised the membrane with the aid of the scalpel and the forceps usually employed in paring vesico-vaginal fistulæ. A perfectly normal cervix and os uteri were disclosed. A glass dilator was worn with intervals for five weeks. The lady was now in the last month of pregnancy. Dr. Mapother regretted he had not searched for muscular tissue, which might have, sphincter-like, excluded spermatozoa. As the aperture in the membrane was above the level of the os, apposition of the meatus with the latter could not occur, and the expulsion of cervical mucus which probably preceded, and the aspiration which succeeded, the ejaculation of semen, would be interfered with. Embryology scarcely explained the existence of such a symmetrical partition in a vagina of otherwise normal form, for the hypothesis of the suppression of one Müllerian canal above, the other below, would be far fetched. While no record of this precise condition existed, cases of double uterus and vagina of the marsupial type, from want of fusion of the Müllerian canals, were pretty frequent. The very dilatable sphincter between the urogenital canal and the vestibule in the monotremes was somewhat similar.

A New Dressing for the Navel.

DORHN recommends (*Centralblatt für Gynäkologie*, No. 14, 1880) the following arrangement in order to avoid the evil effects which occasionally follow the separation of the cord when dressed in the usual fashion. The newly-born child, after having its navel-string tied and cut, is first washed in the usual manner, after which it is laid on a table, and the remains of the navel-string, as well as the parts round about the navel, washed with a 2½ p. c. solution of carbolic acid. The cord is now tied a second time with a ligature which has been duly carbolized, and the superabundant portion of navel-string cut off with its previous ligature attached to it. A layer of carbolized wool is applied over the stump of the navel-string, and over all a portion of sticking-plaster about the breadth of the hand is firmly fastened. This dressing is allowed to remain till the seventh day without being aired or renewed. On removing it then, the remains of the navel-string will be found either nearly or entirely separated. In the former case it is cut off with a scissors. The author declares that he has found this dressing satisfactory in twenty-eight cases.—*Edinburgh Med. Journal*, Sept. 1880.

Etiology and Treatment of Rupture of the Uterus.

Dr. R. FROMMEL states (*Zeitschrift f. Geb. u. Gynäk*, v. 2, 1880) that by palpation of the uterus during a pain, proceeding from above downward on its anterior aspect, he finds that, at a point more or less above the symphysis, the hard, contracted tissue of the uterus ceases to be felt, the portion below this level being soft and flaccid. To recognize this state of things, it is necessary that the voluntary action of the abdominal muscles be kept in abeyance, for which purpose the use of an anæsthetic is sometimes necessary. That the soft tissue below is really a portion of the uterus is shown by the fact that the presenting part of the fœtus can be felt to be contained in it, and also by conjoined examination after delivery; that the condition is not due to pressure against the pelvic inlet is shown by its presence in those primiparæ in whom the head is already within the pelvis before labour begins. This line of demarcation between the contraction and the flaccid portions of the uterus (which Bandl supposed to correspond to the os internum, but which seems to be situated in the proper body of the organ, and which, after Schröder, the author prefers to call the "contracting ring") is generally two or three finger-breadths above the symphysis, often midway between the latter and the umbilicus, and in some instances almost as high as the navel. Where the last-named condition obtains, the intervention of art is needed to prevent excessive distension of the lower segment and consequent rupture, as described by Bandl. The behaviour of the round ligaments is of material aid in diagnosticating this condition of distension.

One of them can usually be seen and felt to stand out more prominently than its fellow during a pain, and it indicates that the distension is greatest on that side—generally the side at which the occiput is situated; the line of demarcation will then be found to run obliquely from below on the side of the least, to a higher point on the side of the greatest, distension.

Seven cases are given in which laparotomy was performed after rupture. They all ended fatally. An eighth case is related in which the rupture took place during the operation of turning by the feet, and in which, before the operation was undertaken, the child was recognized as being almost wholly contained in the over-distended lower segment of the uterus. A drainage-tube was passed into the abdominal cavity through the rent. By virtue of the most painstaking after-treatment, the patient finally did well.

The author considers laparotomy indicated where the fœtus has been expelled into the abdominal cavity; where the secretions are already ichorous; and where there is so much hemorrhage from the rupture as to make it necessary to close it with sutures. Where, on the other hand, the child is living or but recently dead, and it seems possible to deliver *per vias naturales* without inflicting too much injury, and where but a short time has elapsed since the rupture took place, drainage should be the method of treatment. For the first two days we must depend upon the drainage-tube, but, after a wall of exudation has formed, the resulting cavity is to be treated with antiseptic injections.—*New York Med. Journal*, Oct. 1880.

Discutient Treatment of Myomata.

At the recent meeting of the French Association for the Advancement of Science, M. **Courty** read a paper upon this subject. Some myomata, he said, were general, and were treated with tonics, alteratives, and iodide and bromide of potassium; while others were specially in relation with the uterus. M. Courty relied on the following methods: 1. Injections at as high a temperature as the patient could bear (about 113° Fahr.) of water mixed with carbolic acid at the rate of twenty-five *grammes* per *litre;* this was an excellent anticongestive and antihemorrhagic means; 2. Subcutaneous injections of ergotin; 3. The electrolytic action of the continuous current applied by regulated intermittences with a metronome. M. Courty was of opinion that good results were certain if this method were used in the treatment of uterine fibro-myomata.

M. **Verneuil** believed that this method was only successful in about a third of the cases treated. Excellent in cases of fibroma of the congestive type, it had no effect on old-standing fibromata. In cases where profuse hemorrhage was noted, and in which one or two painful points were found in the tumour corresponding to the ovaries, subcutaneous injections of morphia soothed the pain, and also arrested the hemorrhage.

M. Courty allowed that cure could not always be obtained, but said that his method procured, in every instance, real and considerable relief of the suffering. In answer to a question by M. Millard, M. Courty said that an exaggerated value had been attributed to the employment of saline mineral waters in the treatment of uterine fibro-myomata. Alkaline waters were often useful in certain general conditions of the patient.

M. **Denucé** thought that, of all the methods pointed out by M. Courty, the injection of morphia seemed to him the most effective; and he related the particulars of a case of complete resolution of a fibroma obtained in three or four months by this method.—*British Med. Journal*, Sept. 18, 1880.

MEDICAL NEWS.

THE LESSON OF MEMPHIS.

Great calamities like great orators use indeed the same words and inculcate the same wisdom with lesser ones, but speak with an eloquence which carries conviction to a far wider circle of auditors. Hence it is not perhaps too much to hope that the events of the past two years in Memphis will instruct thousands of towns and villages throughout our country in regard to the danger of drinking impure water, especially when contaminated by sewage, and at the same time point out remedies against the virulent and widely diffused disease germs, which cost us in the United States not far from fifty thousand cases of typhoid fever annually.

Every one doubtless remembers the terrible fatality of yellow fever in Memphis during the summer of 1878, and when last year the pestilence reappeared in its limits and was declared epidemic early in August, few thinking men or women failed to reflect that there must be some local cause to account for the unusual prevalence and virulence of the disease in the first instance, and its exceptional recurrence in the second. Thanks to the judicious and energetic labours of our National Health Board under whose auspices a thorough inspection of the "Bluff City" was performed last winter, we have now a positive knowledge of just what was this local cause, which so fearfully intensified the malady; and happily, thanks to the same beneficent organization, the sanitary condition of Memphis has so wonderfully improved that instead of being such an object of abhorrence that its complete abandonment and destruction were to be urged as was done in 1879, the ephemeral press actually recommended it last summer as a health resort.

According to the report of the committee charged with making a sanitary survey of Memphis (Supplement No. 3 *National Board of Health Bulletin*, Washington, D. C., March 1, 1880), the population on January 1st was 30,659 persons grouped in 7384 families occupying 5584 dwellings. The death-rate for three years previous to 1878 was 35 per 1000 (that of Philadelphia being now 17.17), for the first yellow fever year 114 per 1000 and for last year 51 per 1000. Adjoining this record of frightful mortality, which even in non-epidemic years is more than double that of our city of "Healthy Homes," is found the statement that within the city limits were discovered 6000 sub-surface cess-pools in use. These cess-pits were frequently shallow holes without any lining. More than two-thirds of them were in dangerous proximity to living rooms, many being actually excavated in the cellars of occupied dwellings. Besides these cess-pools, there was a large, probably an equal number of disused but unemptied vaults, the contents of which were but imperfectly covered by a thin layer of ashes or refuse. In close juxtaposition to these leaky privy vaults which must necessarily contaminate the soil for at least 30, 50, or perhaps 100 feet around their margins, were situated nearly three-fourths of the wells and cisterns which supplied the inhabitants of Memphis with a larger part of the water they consumed during their brief and feverish existence.

No student of sanitary science will, we presume, attempt to dispute the assertion that such an excessive death-rate, and such an extraordinary degree of water pollution, stand to each other in the relation of effect and cause, or could any doubt exist upon this point it must be dissipated by the positive and gratifying results already attained through the wise measures adopted by the city authorities at the recommendation of the National Board of Health. The precautions thus instituted comprised among others, the cleaning out, disinfecting, and filling up with fresh earth of all privy vaults, both used and abandoned, and the subsequent strict prohibition of any method of dealing with excreta which may cause the contamination of the surrounding soil and resulting pollution of the drinking water in cisterns and wells; the condemnation and destruction by fire of numerous houses, many of them shanties, in the lower districts, the materials of which were so saturated with disease poisons as to render them *foci* of contagion, dangerous to the public health; the enforcement of a system of building regulations providing for the alteration of existing dwellings and the erection of future edifices in accordance with the dictates of sanitary science in regard to ventilation, disposal of excreta, etc., and most important of all, the introduction of a system of sewerage substantially as advised by the well-known expert Col. Waring.

This plan of sewerage, the novel features of which particularly recommend it among communities where economy is an important object, excludes rain-water and subsoil water from the sewers, makes use of earthen pipes instead of brickwork, the dimensions of the conduits being so regulated as to secure a constant flow through them without their being at any time more than half full. According to it the sewers are to be flushed by the flow of a hundred and twelve gallons of water along each branch at regular intervals of every twelve or twenty-four hours, and must be ventilated by freely communicating pipes of their own diameter (4 inches) carried above the roof of each house which they serve to drain.

Such are the warnings which he who runs may read in the colossal letters relating the mournful story of fever-stricken Memphis, but the same sad lesson of preventable disease and death from polluted air or water is told in feebler accents by the sanitary history of a thousand small towns, ten thousand villages, and a hundred thousand country farm-houses throughout our country. In fact until public attention is fully awakened to this wide-spread danger, the philanthropist cannot too often repeat the caution of a distinguished British hygienist, that every case of typhoid should be looked upon, by the owner of a house in which it occurs, as an indication that there is something wrong with the water supply, or else with the method of disposing of the sewage; even if we do not reiterate the sterner *dictum* of another authority "that for each death from typhoid fever, *somebody* ought to be hanged."

—

Yellow Fever on the Lower Mississippi.—A suspicious form of fever made its appearance in the early part of August in Plaquemine Parish, La., on the Lower Mississippi, and by direction of the National Board of Health, Surgeon George M. Sternberg, U. S. A., was detailed to examine the cases and determine the nature of the disease, and as the result he positively asserted the existence of yellow fever of a mild type, with a low rate of mortality, except when the disease was aggravated by vicious local conditions. In the area where this prevailed Dr. Sternberg also found a malarial fever, attributed by the local physicians to exposure in the rice harvest, which they called rice fever.

Drs. Bemiss and Mitchell, of the National Board, endorsed Surgeon Sternberg's conclusions, to wit:—

1. That yellow fever (about 100 cases) existed between August 1 and September 10 in Plaquemine Parish, Louisiana.
2. That the outbreak had its origin in the immediate vicinity of the Mississippi River quarantine station, the first case, August 1, occurring directly opposite the point where the infected bark Excelsior was detained from July 11 to August 16.
3. That while the type of the disease was generally mild, vicious local conditions existed which aggravated it into the most fatal form, four dying in one family out of five attacked.

The National Board of Health immediately placed at the disposal of the Louisiana State Board of Health ten thousand dollars for use in the necessary measures to prevent the spread of the disease. The latter, recognizing only the existence of the so-called rice fever, declined the offer of the National Board, and claimed to have "instituted such measures as it deemed necessary."

—

Mr. Holmes's estimate of Antiseptic Surgery.—Mr. TIMOTHY HOLMES, Surgeon to St. George's Hospital, in his Address in Surgery, before the British Medical Association, paid a high tribute to Dr. Wm. Fergusson's efforts in behalf of Conservative Surgery—the excision of bones and joints, and made the following remark on the obligations of all surgeons to Fergusson's successor, at King's College, Mr. Lister. "It is not necessary," he said, "to believe in all Mr. Lister's theoretical views, in order to admit that no one has had more splendid success in the great object which he proposed to himself—the diminution of the mortality of surgical operations and injuries—and that no one has better deserved the abundant honours bestowed on him from every quarter, and now, I am glad to see, from this University also. When that great career has become a thing of the past, and some worthier orator shall discourse on the services which Mr. Lister has rendered to the world, he will be able to appreciate the value both of the theory and of the practice. The time has not come, I think, to pass any judgment on the former; but I regard it as my duty, as I am sure it is my very great pleasure to take every opportunity of saying that the practice which Mr. Lister has introduced has been eminently successful, and has been the chief cause of the great advance which operative surgery has made in recent years. It is the enviable privilege of King's College Hospital to have been served by two successive Professors of Clinical Surgery who have done more to advance that highest of all the developments of our art than any other men of their generation. Let us mingle with our reverence for the memory of the dead our gratitude for the services of the living."—*British Med. Journal*, Aug. 14, 1880.

—

Medication through the Uterus.—Dr. Robert Barnes, in a recent clinical lecture (*Lancet*, July 24, 1880) calls attention to medication through the genital mucous membrane. He says: "Of late years a method practised by Harvey of washing out the uterine cavity when charged with noxious matter has come into vogue. The favourite agent at present in use is a solution of carbolic acid, and thus we get the twofold good of clearing the uterus of foul matter and of modifying the surface which produced it. But we may, I am persuaded, obtain a third good. We may, by throwing carbolic acid, or, better still, iodine or quinine, or sulphite of soda, into the uterus, chase the septic matters through the tissues and vessels by which it entered. We may thus, whilst cutting off further supply of poison to the system, do much to neutralize the action of that which had already entered."

—

Dangerous Toys.—A plentiful and cheap supply of toys will, it is generally considered, contribute to the happiness of children and the tranquillity of their parents. The recent action of the authorities in Paris suggests, however, that this result may not always be ensured. A toy producing the symptoms of lead-poisoning is not so conducive to the diversion of children and the peace of their parents as the Parisian itinerant vendor of these wares would have us believe. A number of boxes, loaded with toys, painted in brilliant colours, elastic balls coloured and varnished, lead soldiers in every variety of uniform, have been seized by the French police. It has been proved that the colour would easily come off, particularly if the children put the toys to their mouths, a habit which seems inherent in every child's nature. These playthings, painted with poisonous colours, had been imported from Fürth, in Bavaria, and a committee of the manufacturers of that town have recently held a meeting on this subject. A circular was at once issued to all the toy manufacturers, urging them to use non-poisonous paints, and reminding them that according to the German law they had exposed themselves to penalties—fines and imprisonment. The *Gesundheit* of Frankfort justly remarks that but for the repressive measures adopted in Paris the German authorities would still neglect to enforce the German law. This apathy, according to the German papers, is all the more reprehensible as the Fürth manufacturers send their toys all over Germany, and may therefore poison the children of the fatherland as well as the little Parisians—a consideration which, in the Teutonic mind, must greatly accentuate the gravity of the question. To us the matter is not less serious. It is well known that the majority—in fact, nearly all—of the cheap toys sold in England are imported from Germany, and we regret that it is to the Parisians rather than to the English authorities that we must attribute the honour of seizing these dangerous playthings. We trust that no time will be lost in following this excellent example, and that a more strict watch will be kept to prevent the importation from abroad of poison for the nursery.—*Lancet*, Aug. 7, 1880.

—

Prize Essay on Hydrophobia.—The prize of £100, offered by Mr. V. F. Bennett-Standford, for the best essay on Hydrophobia, its nature, prevention, and treatment, has been awarded to Mons. Bourrel, of Paris. It will be remembered that, at Mr. Bennett-Standford's request, the Royal College of Physicians undertook the responsibility of awarding the prize, and that they appointed a very competent committee to examine and report on the essays that might be sent in. The College, when publishing the conditions of the competition, set out several questions as especially needing investigation: such as, namely—the history and origin of outbreaks of rabies, especially in the United Kingdom and its dependencies; the best mode of prevention of rabies; the characteristics of it during life, and the anatomical and chemical changes associated with the disease, particularly in its commencement; the origin of hydrophobia in man; the chemical and anatomical morbid changes observed in the subjects of the disease; with special reference to any such changes in the nervous system, and in the salivary glands; the diagnosis of the disease in doubtful cases; the alleged prolonged latency of the malady; and the subjects of treatment, prophylactic and curative. Nineteen essays, some of them of very considerable length and fulness of detail, were received; and the labour of examining them critically must have been anything but a light one. But the adjudicators have, within a very reasonable time, presented their report, upon which the prize has, as stated above, been awarded to Mons. Bourrel.—*Med. Times and Gazette*, Aug. 21, 1880.

—

Remedies for Tænia.—Dr. BERENGER FÉRAUD, as a result of trials on a large scale of the different remedies for tænia, comes to the conclusion that the most powerful and certain of these is pelletiérine, the active principle of pomegranate bark.

—

A Munificent Bequest.—FRANCESCO RIZZOLI, Professor of Surgery at the University of Bologna, who died recently, has bequeathed his vast wealth, estimated at nearly 6,000,000 francs, to the Municipality of Bologna, with the stipulation that it should be devoted to the completion and maintenance of the Model Orthopædic Hospital on his estate at San Michele, in Bosco, an institution on which he had, during his lifetime, expended a sum of 2,000,000 francs.—*Lancet*, Sept. 18, 1880.

—

Cremation.—A memorial in behalf of cremation was largely signed at the Cambridge meeting of the British Medical Association. Mr. Spencer Wells has it in charge.

—

Bad Food at Bellevue Hospital.—The House Staff at Bellevue Hospital complain in the *New York Tribune*, that their food is of such wretched quality, and so badly cooked that it is impossible to live on the hospital fare alone, and that as a result of the diet, about one-half of the staff are worn out and sick upon the expiration of their term of service at the hospital.

—

Hospital Sunday.—The London Hospital Sunday Fund of the present year has reached upwards of $130,000.

—

Canada Medical Association.—The thirteenth annual meeting of this association was held at Ottawa, September 1st and 2d, Dr. R. P. Howard, of Montreal, President, in the chair. The Americal Medical Association was represented by Drs. Brodie, of Michigan, and Brush and Goodwillie, of New York. The following officers were elected for the ensuing year: President, Dr. Caniff, of

Toronto. Vice-Presidents, Drs. J. A. Mullin, G. E. Fenwick, McNeil Parker, and J. Christie. General Secretary, A. H. David, M.D., of Montreal. The next meeting will be held at Halifax on the first Wednesday of August, 1881.

American Academy of Medicine.—The fifth annual meeting of the Academy was held at Providence, September 28th and 29th. Dr. F. D. Lente, of New York, President, in the chair. Twenty-four of the one hundred and nineteen members were present. Dr. Lente delivered the annual address upon the Higher Education of Medical Men, and its Influence upon the Profession and the Public.

The following officers were elected for the ensuing year: President, Dr. Edward T. Caswell, of Providence, R. I. Vice-Presidents, Drs. H. O. Marcy, of Cambridge; W. T. Taylor, of Philadelphia; Howard Pinkney, of New York; and Horace Lathrop, of Cooperstown. Secretary and Treasurer, Dr. R. J. Dunglison, of Philadelphia. The next meeting will be held in New York, on the third Tuesday in September, 1881.

The American Public Health Association will hold its eighth annual meeting in New Orleans, December 7th, 1880, under the Presidency of Dr. John S. Billings. Papers will be presented on Abattoirs, Epidemics, Life Insurance in its relation to the Public Health, The Storm-water question in City Sewerage, The Sanitary Engineering problems of the Mississippi River, The Hygiene of Emigrant Ships, The prevention of Venereal Diseases, Voluntary Sanitary Associations, etc. etc.

The special questions suggested for discussion at this meeting in addition to those connected with the papers above referred to, relate to methods of preventing the spread within a town or city—after they have once been introduced—of such contagious or spreading diseases as Diphtheria, Scarlet Fever, Yellow Fever, Measles, Smallpox, etc., and are as follows:—

1. What are the best means of securing prompt and reliable information as to the presence and location of cases of such diseases?
2. What are the best means of securing isolation of the first or of single cases of such diseases, and what are the chief difficulties in securing such isolation?
3. Under what circumstances is it proper to declare such diseases epidemic in a place?
4. Under what circumstances is it proper to recommend the closure of schools on account of the prevalence of such diseases?
5. What precautions should be taken at the termination of each case as to—
    a.—Care and disposal of the dead?
    b.—Disinfection and cleansing of the room and house?
    c.—Period of time at which it is safe to allow the convalescent to return to school or society?

Removal.—The *Editorial* office of the *American Journal of the Medical Sciences* and of the *Medical News and Abstract* has been removed to No. 237 South Eighteenth Street, Philadelphia.

To Readers and Correspondents.—The editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

HAMILTON ON FRACTURES—New Edition—Just Ready.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. By **Frank H. Hamilton**, M.D., LL.D., Surgeon to Bellevue Hospital, N. Y., etc. Sixth edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5 50: leather, $6 50; half Russia, raised bands, $7 00.

The demand which has so speedily exhausted five large editions of this work, shows that the author has succeeded in supplying a want, felt by the profession at large, of an exhaustive treatise on a frequent and troublesome class of accidents. The unanimous voice of the profession abroad, as well as at home, has pronounced it the most complete work to which the surgeon can refer for information respecting the details of the subject. In the preparation of this new edition, the author has added a chapter on General Prognosis; that on Fractures of the Patella has been entirely rewritten, in order that the results of a recent exhaustive study of this subject might be given, and, in fact, the entire matter of the book has undergone most thorough revision. A number of illustrations have been omitted to make place for new ones, and a few have been inserted from the German edition, published at Göttingen in 1877.

WELLS ON THE EYE—New Edition—Just Ready.

A TREATISE ON DISEASES OF THE EYE. By **J. Soelberg Wells**, late Professor of Ophthalmology in King's College Hospital. Third American, from the third English edition. Thoroughly Revised, with copious notes and additions, by **Charles S. Bull**, M.D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with over 250 engravings on wood and six colored plates, together with selections from the test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50.

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science. The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

SOLD ONLY BY SUBSCRIPTION.

REYNOLDS'S SYSTEM OF MEDICINE. Revised Edition. Complete in 3 Vols.

A SYSTEM OF MEDICINE. Edited by **J. Russell Reynolds**, M.D., Prof. of the Principles and Practice of Medicine in University College, London. With notes and additions by **Henry Hartshorne**, M.D., late Prof. of Hygiene in the Univ. of Penna. In three large and handsome royal octavo volumes, containing 3052 closely printed double-column pages, with 317 illustrations.

PRICES.

	Cloth.	Sheep.	Half Russia.
Per volume	$5.00	$6.00	$6.50
Per set	15.00	18.00	19.50

Reynolds's System, as a work of reference in medicine, is unexcelled and unequalled, and should be in the library of every physician. Dr. Hartshorne, the American editor, has contributed articles on cholera morbus, cholera infantum, trichina spiralis, bronchocele, pernicious anæmia, and spermatorrhœa, besides making such additions to many other articles as the progress of medical science since the volumes first appeared, required. The task he undertook has been well performed, and the thanks of all American physicians are due to the American editor for affording them the opportunity of obtaining at a reasonable price such a magnificent cyclopædia of the practice of medicine, embodying as it does the views of the most learned members of the medical profession of Great Britain. We earnestly advise all our readers to buy the volumes and *read them.—Canadian Journal of Medical Science*, October, 1880.

Regarding the work as a whole, we give it our earnest commendation. It places within the reach of the average physician a series of monographs, written by some of the most eminent men of the age, upon an extremely wide range of subjects. It is the latest and best cyclopædia work on practical medicine written in our language.—*St. Louis Clinical Record*, August, 1880.

Valuable as the work was when issued in England, the labors of Dr. Hartshorne have added very greatly to its worth, and it can now but be regarded as the best encyclopædia of medicine extant.—*American Practitioner*, August, 1880.

These three ponderous volumes contain a vast amount of valuable information; as works of reference in the library of the discriminating practitioner, the medical investigator, and the medical teacher, they are of real value.—*Chicago Medical Journal and Examiner*, August, 1880.

It gives us pleasure to recommend most cordially this System of Medicine, not merely to the student, but also to the busy practitioner of medicine.—*Amer Journ. of Med. Sciences*, August, 1880.

In style, economy of space, clearness, and brevity; in comprehensiveness, excellence of description, and practical utility, it is admirable.—*Chicago Med. Review*, July 20, 1880.

HENRY C. LEA'S SON & CO., Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing the fourth year of its second half century, the publishers of the "American Journal of the Medical Sciences" have much pleasure in assuring its wide circle of readers that at no future period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "The Medical News and Abstract," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of Five Dollars *per annum.*

The "News and Abstract" consists of sixty-four pages monthly, in a neat cover. It contains a Clinical Department in which will be continued the series of Original American Clinical Lectures, by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "Monthly Abstract," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an Editorial and a News Department, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "News and Abstract" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "American Journal of the Medical Sciences," to all who remit Five Dollars in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The American Journal of the Medical Sciences, published quarterly (1150 pages per annum), and The Medical News and Abstract, published monthly (768 pages per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The American Journal of the Medical Sciences, when not paid for in advance,	Five Dollars.
The Medical News and Abstract, invariably in advance,	Two Dollars and a Half.

⁂ Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the Journal (two annually) and the News and Abstract (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "Journal" and "News and Abstract" may be made at the risk of the publishers by forwarding in registered letters. Address

MEDICAL NEWS

AND

ABSTRACT.

A CONSOLIDATION OF THE "MEDICAL NEWS AND LIBRARY" AND THE "MONTHLY ABSTRACT OF MEDICAL SCIENCE."

EDITED BY

I. MINIS HAYS, A.M., M.D.

PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1880.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1880, by HENRY C. LEA'S SON & Co., in the Offi
of the Librarian of Congress. All rights reserved.

NEW MEDICAL BOOKS, IN PRESS.

FLINT'S PRACTICE—New Edition.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE. designed for the Use of Students and Practitioners of Medicine. By **Austin Flint**, M.D., Professor of the Principles and Practice of Medicine and of Clinical Medicine in Bellevue Med. College, N. Y. Fifth edition, thoroughly revised and much improved. In one large and closely printed octavo volume of about 1100 pages.

EXTRACT FROM THE AUTHOR'S PREFACE TO THE FIFTH EDITION.

In preparing the fifth edition of this treatise, the author has been thoroughly mindful of the progress of medicine since the publication of the fourth edition, in 1873. Time and labor have not been spared in the endeavor to bring the work, in all respects, up to the present state of medical knowledge.

Dr. William H. Welch, lecturer on Pathological Histology in the Bellevue Hospital Medical College, has contributed in Part I. the first seven chapters, embracing the general pathology of the solid tissues and of the blood. He has also revised, and in great part rewritten, the descriptions of the anatomical characters of the diseases considered in the rest of the volume. It is believed that these portions of the work will serve as a digest of the essential facts pertaining to general and special pathological anatomy, as far as this important branch of study bears upon practical medicine.

In the other portions of the treatise many changes will be found, which have somewhat enlarged the size of the volume, in spite of the omission of a considerable amount of matter, and the rewriting of many portions with a special view to condensation. Among these changes may be mentioned numerous improvements in the arrangement, including the classification of the diseases of the nervous system on an anatomical, in place of a symptomatic basis, and the consideration of various diseases not embraced in previous editions. In short, the eliminations, substitutions, and additions, render the present edition virtually a new work.

In making changes, the author has not been influenced by any sense of obligation to maintain consistency of views with the previous editions of this treatise, or with other works which he has written. If statements be found to vary from those made at a prior date, the simple explanation is that the latter, in the light of more recent reflection and enlarged knowledge, seem to him no longer tenable. He has endeavored to regard his own past writings in this point of view, divested of the partiality of authorship, and to subject them to as critical an examination as if they were the writings of another.

BRYANT'S SURGERY—New Edition.

THE PRACTICE OF SURGERY. By **Thomas Bryant**, F.R.C.S., Surgeon to Guy's Hospital. Third American, from the second and revised English edition. Thoroughly revised and much improved, by **John B. Roberts**, M.D. In one large and very handsome imperial octavo volume of over 1050 pages, with 672 illustrations.

The marked success of this work on both sides of the Atlantic shows that the author has succeeded in the effort to give the student and practitioner a sound and trustworthy guide in the practice of surgery.

In preparing a new edition, it has seemed best, in order to adapt the work more thoroughly to the needs of the native student, that it should receive the benefits of a revision by an American editor, who should not only incorporate the most recent discoveries, but also the modes of procedure which must necessarily vary with the practices of different countries.

The work is now confidently presented as worthy a continuance of the very distinguished success which has marked the reception of the previous editions.

ALLEN'S ANATOMY—Shortly.

A SYSTEM OF HUMAN ANATOMY: INCLUDING ITS MEDICAL AND SURGICAL RELATIONS. For the Use of Practitioners and Students of Medicine. By **Harrison Allen**, M.D., Prof. of Comparative Anatomy and Physiology in the Univ. of Pa. With an Introductory Chapter on Histology, by E. O. **Shakespeare**, M.D., Ophthalmologist to the Phila. Hospital. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text.

In this elaborate work, which has been in active preparation for several years, the author has sought to give, not only the details of descriptive anatomy in a clear and condensed form, but also the practical applications of the science to medicine and surgery. The work thus has claims upon the attention of the general practitioner as well as of the student, enabling him not only to refresh his recollections of the dissecting room, but also to recognize the significance of all variations from normal conditions. The marked utility of the object thus sought by the author is self-evident, and his long experience and assiduous devotion to its thorough development are a sufficient guarantee of the manner in which his aims have been carried out. No pains have been spared with the illustrations. Those of normal anatomy are from original dissections, drawn on stone by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, after the manner of "Holden" and "Gray;" and in every typographical detail it will be the effort of the publishers to render the volume worthy of the very distinguished position which is anticipated for it.

CLINICS.

Clinical Lectures.

ON COLOUR BLINDNESS.

A CLINICAL LECTURE DELIVERED AT THE JEFFERSON MEDICAL COLLEGE.

BY WILLIAM THOMSON, M.D.,
PROFESSOR OF OPHTHALMOLOGY IN THE JEFFERSON MEDICAL COLLEGE, ETC.

GENTLEMEN: The serious optical defect which I shall describe to you to-day has recently evoked a discussion throughout the civilized world, which has gone far beyond the limits of our profession, has excited the attention of the public everywhere, and has produced an agitation which has led to important legislation in Europe and America, and will not cease until, by the aid of experts in our profession, codes and laws have been enforced to permit ships to sail our rivers and cross our oceans without fear of collisions; and trains on our railways to rush over our land, by day or night, under the protection of wise, scientific regulations for the avoidance of preventable accidents.

The ships of all nations are compelled by law to expose, on the port side, a red light, and on the starboard a green light, from sunset to sunrise, to indicate beyond doubt the course of the ship. No other colours can be used, and these are the ones most likely to be confounded by those colour blind, so that accidents must have been, and will again be, caused by the mistake of one ship manœuvring to avoid a collision with the other under the idea that it was receding when it was approaching, the result being to bring them into contact. The law compels all steam vessels to avoid the sailing craft, and makes the former liable in damages for all losses; and I have been informed by a prominent lawyer in Baltimore, who is counsel for several steamship companies, that he is satisfied that many cases in which he has defended his companies for injuries done to sailing vessels in Chesapeake Bay, could be accounted for in no other way than by supposing that the look-out on one or other boat was colour-blind.

In the railway service the most important orders are transmitted by colours, and the safety of an entire train depends upon whether these instructions are recognized and obeyed at once. A white light, flag, banner, or other object, indicates *safety*, and is a permission to the engineer to proceed with speed. A green colour indicates *caution*, and directs him to be on guard, and to run slowly, and to be notified that there is danger; whilst a red signal orders him to stop at once. Where the "block signal" system is in use the road is divided into short sections by stations with telegraphic operators, and each section is protected by the red signal, which bars that section so long as a train is passing between that and the one next to it; when the second station is passed, the operator telegraphs back to the first one, the white signal is displayed, and the next train can proceed. This seems the only way to avoid those collisions that yet occur on the double track roads when trains are passing in the same direction. The last serious accident of this kind, in which thirty people lost their lives, occurred by the over-crowding of the rear platform of a car at the end of a train, held at a block station, so that the danger signal of red lights could not be seen by the engineer of an advancing train just leaving a depot. Whilst these signals are used, the engineers are willing to obey the stern demands of the public that they shall be hurried over the roads at the greatest speed, and with the least loss of time. All these precautions are rendered unavailing if an engineer, knowing of no imperfection himself, has the defect called colour blindness, and is hence unable to understand the sentiment conveyed by the colour, and confuses hopelessly the perhaps soiled white or gray of safety with the precautionary green, or the green of danger, with the peremptory halt of the red colour.

Three monographs have been published on this affection—one by Prof. Wilson, of Edinburgh, in 1855, now out of print; another by Prof. Holmgren, of Sweden, on "Colour Blindness, and its Relations to Railways and Marine," partly translated by our Smithsonian Institution; and a third, the most complete, by Dr. B. Joy Jeffries, of Boston, in 1880, on "Colour Blindness; its Dangers and its Detection." And to the latter I would refer those who desire to acquaint themselves minutely with all that is known historically and scientifically of this now important subject. To the energy and the wise and well-directed labours of Dr. Jeffries we owe all of the efforts that are now being made to influence the General Government at Washington, the Legislatures of States, and the Managements of our great steamship and railway companies to perfect and insist upon the examinations of all persons who are placed in positions where the safety of life and property may be endangered by a defect in the colour perception.

To his Majesty the King of Sweden belongs the credit of having promptly shown his practical good sense in adopting and applying in his country the proposals and methods submitted by Prof. Holmgren, and his example has been followed by the most important continental nations. No action has been taken by the English Government, but under the advice of scientists most of the important railways have instituted examinations for themselves. Here, the Army, the Navy, and the Marine Hospital service have taken independent action, but have not, as yet, adopted any general standard. All recruits for the army are now examined for colour blindness, and although this is not a cause for rejection, those found defective are disqualified for service in the signal corps. The cadets at West Point are also examined previous to their admission. The Surgeon-General of the Navy has ordered examinations by the medical officers of all persons in the navy; and in the merchant marine, all persons applying for a license as pilot must submit a certificate from a physician that the colour perception is good. This is a step in the right direction, but Dr. Jeffries has been urging Congress, aided by petitions signed by prominent ophthalmic surgeons and other scientific gentlemen, to aid in calling, in conjunction with foreign governments, an interntional congress, to which should be referred the task of establishing international standards of visual acuteness and colour perception. These advances are in response to the action of the ophthalmic section of the British Medical Association, which has passed resolutions, and forwarded them to the British Government, and to the International Ophthalmological Congress which recently met at Milan. It is to be hoped that our government may take favourable action this winter, and appoint persons to represent our interests at that congress.

You may well ask me now, What is colour blindness? It means that, with the most perfect sharpness of sight for "form," a person may be unable to distinguish between two colours as pronounced as bright red and pure green; to whom the crimson cherries on a tree, although perfectly recognized, would have the same colour as the green leaves. Remember, there is no blindness proper—all coloured objects are seen; but these colours are not recognized as the normal-eyed persons see them. The colour-blind see yellow and blue or violet with normal perception perhaps, but are unable to see any violent contrast between green and red, and would, perhaps, match a red with a green colour. I speak, now, of what we call, practically, colour blindness, since I must say that more scientifically it means one class who are green-red colour-blind, and so numerous as to number four in every hundred men; and a second class, viz., violet-yellow blind, so rare as to be seldom observed; so that hereafter we will be understood when we speak of men colour-blind, to include those who see only yellow and blue, but have the green and red tints undistinguishable. It must also be remembered that the colour-blind are often ignorant of the defect, that they see coloured objects, and distinguish them by the same names that others not colour-blind do, and that their defect cannot be ascertained by asking them to give names for colours, but that all our tests, therefore, are now based upon their inability to select colours to match those that are submitted as tests. Dr. Jeffries sums up this subject by stating that "the colour sense of colour-blind may be described as follows: The red-blind sees all objects of this colour of a darker hue than they are. The same of the green-blind as to green. Both confound these colours with each other and gray. A mixture of white and black in proper proportions to represent the luminosity of any shade of red or green will give the colour-blind the same sensation as that shade. The violet-yellow-blind will do the same in reference to all colours containing either of these two. Violet blindness is so extremely rare, and not causing danger on land or sea, we may omit special discussion of it."

Imagine, now, a beam of white light decomposed by a prism into the spectrum, and projected on a screen; where the normal eye would perceive the violet, indigo, blue, green, yellow, orange, and red, in all their purity and beauty, the colour-blind see it where the violet, and blue, and the yellow colours exist; the green is light-gray, and the orange and red are gray and brown, and hence all objects which reflect green and red are to them nearly alike in tint or colour.

The theoretical discussion of this defect would lead us too far, and would involve many theories of physiological and mathematical laws of light, which can be found in the book of Dr. Jeffries. But I will only say, that we believe that this defect is due to a congenital want in the retina of those minute nervous elements which are stimulated, and which respond to those vibrations of light which we call red and green.

It may interest you to know that we are all in a measure colour-blind, inasmuch as our retinæ are so constructed that we have the full colour perception only at the fovea, or yellow spot, where the acuteness of vision also is the highest. We all know that without moving the eyeball we have but a small portion of the field of vision where we can perceive small objects. In reading a line of print we are obliged to move the ball so as to bring one word after the other into view, and are unable to grasp more than a small area with perfect fixation. When we experiment with coloured objects we find that the colour sense diminishes from the centre to the periphery of the field of vision in the same way that the colours of the spectrum are arranged. All the colours are seen in the small central point of view, but as we move a coloured object away from this point, without altering the point of view of the eye, the red colour is lost first, then the green, and, finally, the blue. The retina then consists of zones of different power of colour perception in the normal eye, and we are thus able to convince ourselves, by placing a vivid red a short distance from the point of fixation, that it is soon devoid of its intense colour and becomes a dusty brown; green can be recognized as a tint still further, and blue can be seen at the periphery of the field.

Is this defect frequently observed? The reports of the testing of thousands and thousands of men leave no doubt whatever that one man in every twenty-five is colour-blind as to red and green. These statistics include men of all ages—the old, and the young in schools. Dr. Jeffries alone has reported 18,000 examinations, and the percentage is always found to be a little over 4 per cent.

Its cause is congenital, frequently inherited, and is, so far as we now know, entirely incurable. Acquired colour-blindness is known to be one of the signs of inflammation of the optic nerve, ending in atrophy and blindness, and is also produced by the abuse of tobacco and alcohol, or may follow injuries affecting the head or eyes, disease of the brain, or long-continued illness, such as typhoid fever.

The most curious and unintelligible aspect of this strange defect is its rarity in the female sex, since but 1 woman in nearly 4000 was found completely colour-blind as reported in the statistics of Dr. Jeffries, against 1 man in 25.

Accept this fact, that 1 male in every 25 is born colour-blind, and is incurable, and you will realize how important it is that all males in our schools should be carefully examined before selecting any of the various trades or pursuits in which a full colour sense would be necessary for success. It is to insure safety to the growing numbers of travellers by land and water, however, that I urge upon you an acquaintance with the facts in regard to this defect, and its detection, which has now been rendered very simple.

Since the colour-blind see tints and learn to give them the names we all use, it is simply impossible to detect the colour defect by showing colours and asking them to name them. The test now accepted as the most prompt and practical is the one which Prof. Holmgren has introduced, and which is based upon the power of the normal eyes, to select from many colours offered them those to match some given test colour.

The apparatus needed then is a collection of skeins of ordinary worsted, about one hundred and fifty in number, including shades of every colour from white, through the tints of the spectrum to black; and three large test skeins: I. of pure green, light in tint; II. of rose or purple, a mixture of red and blue; and III. of pure red. This selection has been well revised, and can be obtained from the dealers in optical apparatus. These colours mingled together, placed on a white cloth in a good light by daytime (since no examination can be made by the yellow flame of a lamp, candle, or gas-burner) should be exposed to the view of the person examined, and he should be told to select any tints which would resemble the test skein No. I. light green, which should be placed by itself at a short distance away. The selection should be continued until a number of skeins have been chosen and thrown aside, and if only green are taken we may proceed to the next test. Where colour-blindness exists skeins of light or darker gray, light brown, or even red may be selected with test I.

Test II. is a rose or purple, and, as it is composed of red and blue, the red blind see it only as blue, and match the rose with blues, whilst the green blind select greens.

Test III., the pure red skein may then be used, and these colour-blind will select from the mass of worsteds the browns, sages, or greens, and thus betray their defect, not only by their failure to match, but by the fact that they overlook and put aside or reject colours which do match. The tints which the colour-blind select to match the large test skeins are called "colours of confusion," and they become well known to the surgeon who makes much use of this method.

Briefly, those who, with the *green* test, select grays, light browns, tan-colours, or light reds or pinks are colour-blind; but we desire to know whether they are to be classed as red or green blind, and for this purpose we notice the shades selected for the *rose* test; those who select blue and violet tints are completely *red blind;* those who select gray and green tints or any of them are completely *green blind.*

Finally, to convince any who doubt, although it is not even necessary to decide if the defect be red or green blindness, test III., the *red,* is presented, a vivid colour, like the flags used on the railways, and the examination should continue until all the tints of this colour, or a number of "confusion colours," have been placed aside; the red blind will choose, beside red, green and brown shades, which seem to the normal sense *darker* than red; on the contrary, the green blind will select opposite shades, which seem lighter than red.

Although we may classify the colour-blind into red and green blind, yet practically they both show an inability to distinguish between these, the two colours which after long experience have been selected for the important signals on land and sea; and no one can witness the examination of a person colour-blind for the first time without a deep conviction of the danger that would be incurred by leaving the safety of a ship or train to a person so unfortunately defective.

Observe now the movements of this patient when directed to look at the test I., or light green, placed three feet away, and to match the colour from the confused mass of coloured skeins placed before him on the table. He turns over the tints, looks again and again at the test, selects slowly a green, which I silently place on one side; he again with a curious movement of his hands, which betrays his defect, pushing aside the greens, which we all recognize in the worsteds, and failing to pick them out, he chooses this gray skein—now this tan colour—now another green—now a gray—now a darker tan; so we now present you his selection, which may well cause you surprise. Let us now ask him to match test II., this purple skein, and you perceive he selects now more promptly either purple, since they look the same, or these blues, for the man is red blind and cannot see the red colour in the mixture of red and blue which makes the purple of our test skein. Had he been more green- than red-blind he would have picked out some green and gray tints to match the purple. No one can doubt his inability to understand what we mean by colours. But we will finish by asking him to match this bright red test, No. III., and you see he selects about half his skeins of red, and the rest of dark brown.

There are perhaps ten other and more complicated methods for diagnosis of colour defect, but that of Holmgren is universally regarded as the most simple, and as giving prompt and decisive results, and for this reason I will not detain you by their descriptions.

Having been requested to aid the Pennsylvania Railway in having their employés examined, I have been compelled to devise an instrument, based on Holmgren's system, which would enable the test to be applied without the presence of any medical man, and the facts of the matching to be recorded for future reference. This became necessary from the fact that it has been found requisite to ascertain not only the colour sense, but the acuteness and range of vision, the field of vision, and the hearing, of all the employés; and as these numbered about thirty-five thousand, scattered over twenty-five hundred miles of road, and as there were not available a sufficient number of ophthalmic surgeons to make the examinations and to decide judicially and finally, therefore some other means were necessary to collect all the information, and bring it before the person who would take the responsibility of deciding upon the fitness or unfitness of the employés. A general system has been perfected and has been used for over two thousand examinations, which has fulfilled the above indications, and will soon be put in force over the entire road, by which, upon a blank, all the facts requisite for a decision can be placed by any intelligent non-medical person.

For the colour perception I have used an instrument composed of two narrow, flat sticks hinged together at one end, and fastened by a catch at the other, between which are forty buttons attached to one stick, but capable of easy removal or transportation, and each one numbered from 1 to 40, the numbers being concealed by the second stick. To each button is attached a skein of worsted arranged on the following theory: Experience has taught me the "confusion colours" for the three *test* colours, viz., green, rose, and red; and I have used in my arrangement only the real colours like the *tests*, and the "confusion colours," omitting all the others and reducing the number from 150 to 40. The first twenty buttons have attached on the odd numbers various tints and shades of green, and on the even numbers the known "confusion colours," grays, tans, light browns, etc.; and this half is for the diagnosis of colour blindness. The second series, from 21 to 30 have the rose or purples on the odd numbers, and blues on the even; and the third from 31 to 40 have alternately reds and the proper confusion colours for red, viz., browns, sages, and dark olives.

A man is now placed before this instrument and told to select ten tints to match the *green* test, and if he has colour sense perfect, he promptly turns up over the stick the ten green skeins; a clerk then examines the numbers on the ten buttons, and he will find and record on a blank only odd numbers; the second, *purple*, test is then similarly treated, and next the *red*, and if no defect is found nothing but odd numbers are recorded. When colour-blindness is found the confusion colours, with all the tests, are on the even numbers on the buttons, and a glance at the record enables an absent supervising officer to know that the man must be colour-blind, and to verify the examination by referring to a similar instrument in his own possession.

It would be a fault if an examination should show with Test I. even numbers between 1 and 20, or any number beyond 20, for a colour-blind might select a red between 30 and 40, to match the green test; with purple test anything recorded between 20 and 30, except odd numbers, or any number below 20, or beyond 30, would indicate colour defect, and in like manner anything but odd numbers between 31 and 40 for the red test, would proclaim the defect. No great skill, and no professional knowledge is needed to make this record, and the theory of the arrangement is so simple that a glance enables one to know, from the written report of the examination, the exact colours that were selected, and to decide if they were indicative of colour blindness. I have been compelled to use this plan, or give up the hope of having these examinations made on our large railways, and that it has been entirely successful in the hands of several different examiners, whose reports have all been carefully scrutinized, is known by the fact that over four per cent. of the men have been found colour-blind, although the instrument was then less complete than it is at present, thus giving the percentage to be expected from the labours of other careful and professional observers. Many of these men were also tried by the banners and flags by daylight, and by coloured lamps by night, such as are daily and nightly in use on the road, and they made the mistakes that would be predicted from their test examinations, being unable to distinguish at once and infallibly between the soiled white (gray) flag and the green, or between the green flags and lights and the red ones.

We may conclude by the brief statement that one male in twenty-five is colour-blind, and perhaps does not even suspect it; that it is largely hereditary and congenital, and when so incurable, but may be caused by injuries, illness, or abuse of alcohol and tobacco; that he cannot correctly see the signals when dependent on colours; which experience has shown must be employed on the water and on railways, and that he is necessarily incapable of service on railways or on shipboard where his defect might lead without any doubt to the most serious disasters. The methods of examination have been rendered easy and sure, and it remains for us as protectors of the public health and safety, to do all in our power to aid the management of our railways and ships to eliminate this danger from the risks of travel.

PART OF A CLINICAL LECTURE ON AUDITORY VERTIGO.

Delivered at the National Hospital for the Epileptic and Paralyzed.

By J. HUGHLINGS JACKSON, M.D., F.R.S., etc.
Physician to the Hospital.

GENTLEMEN: We are occasionally consulted by patients for attacks of vertigo. Sometimes the attack is epileptic, and then the case is infinitely serious; sometimes, at least many think so, it is owing to dyspepsia only, and then it is a thing of comparatively little gravity. Vertigo occurs occasionally as a result of sexual excesses. Some weakly people are giddy and totter if they get up quickly from the recumbent position, but here the attack, if we may call it one, is artificially produced. There is another kind of vertigo which has long been known, but which is not yet widely known—auditory vertigo, or as it is often called, Ménière's disease. It is quite certain that paroxysms of exceedingly severe vertigo occur with ear disease. No experienced person can deny that, even if he denies that there is a relation of cause and effect. Whilst auditory vertigo is the most distressing to the patient, epileptic vertigo is infinitely the most serious of all paroxysms of vertigo. Epileptic vertigo, I must tell you, is often used as a name for a very slight attack of epilepsy—for cases in which there is no true vertigo. I think it would be better to use it as a name for vertigo in slight epileptic paroxysms, or at the onset of severe ones. Thus, if a patient has, in a slight paroxysm of epilepsy, or at the onset of a severe one, the sensation of external objects moving, or of himself moving, I call that sensation epileptic vertigo. I do not call a very slight attack of epilepsy epileptic vertigo if there be neither of these sensations. In no case, indeed, do I conclude that a patient has vertigo unless I learn from him that objects appear to him to move, or that he feels to move.

The diagnosis of the nature of an attack of vertigo is not always easy. We ought to investigate the simpler cases first. There is a very important vertigo we have yet to mention; one, however, which does not come on in attacks; it comes on when the patient walks. I mean vertigo from paralysis of an ocular muscle, or of several ocular muscles. To study vertigo in cases of paralysis of ocular muscles is the most methodical way of beginning the study of vertigoes in general. I think it is unwise to study auditory vertigo and epileptic vertigo before carefully investigating the much simpler case of vertigo from paralysis of ocular muscles.

Our subject to-day is auditory vertigo.[1] The term does not suggest the whole symptomatology of the affection it names, there is much more than giddiness with ear disease in a severe attack. The patient consults you for attacks of giddiness with vomiting, but the symptomatology is usually very much wider than this even. He will tell you that suddenly things seem to move—to move to one side, or to whirl round, or that he himself feels lifted up or pushed forwards. He is unsteady, and his gait is a reel, if walking be possible at all. Even when lying down he feels unsafe, and will grasp the sides of the couch. If he moves his head he is worse. The above vertigo, with reeling, is only one-half of the patient's condition. We may call the two symptoms we have mentioned locomotor symptoms. Vertigo is on the physical side incipient or rudimentary disorder of locomotion. The following additional symptoms we may call "vital." We see that the patient is pale and haggard, that there is profuse perspiration. He tells us that he feels sick, and he may vomit. He has horrible depression, he may say that he feels as if he were going to die. and not unfrequently compares his condition to that in sea-sickness. Another symptom is pain in the head.

The paroxysm may last an hour or more. I have described what occurs in a severe attack; there are minor attacks, such as a little transitory giddiness and unsteadiness. There are also still severer attacks; sometimes the patient loses consciousness. A medical man told me that the first attack occurred in the streets in London. He was taken to a hospital unconscious, and remained so for three hours. Such a seizure would give us a hard task in diagnosis from epilepsy. Subsequently he had attacks without loss of consciousness.

---

[1] Brown-Séquard in his lectures, "Physiology and Pathology of the Central Nervous System," 1880, p. 195, and also in "Experimental and Clinical Researches, etc.," 1853, drew attention to the serious disturbance resulting from lesions of the uditory nerves.

In these cases there is "something wrong with the ear," or ears. Sometimes the patient has been long deaf of one ear before any attack; occasionally it happens that he is rendered deaf at his first attack; there is in other cases great noise in one ear when the paroxysm sets in, or an increase of a noise which exists betwixt the paroxysms.

In these cases the ear is the part in fault. But manifestly all the symptoms we spoke of as locomotor and vital are owing to something wrong with nervous centres. We may put it that the ear is in fault, and that the centres suffer. But this is not, I think, without qualification. Borrowing an idea from Sydney Ringer as to diminished resistance of centres in cases of migraine, I would suggest that any general lowering of health will be a factor in the production of auditory vertigo; the resistance of nervous centres being diminished, they more readily give way to the "irritations" by the ear. In another way of putting it we may say that the nervous centres are healthy in auditory vertigo, except, perhaps, for a defect in their nutrition in common with the rest of the body. They are, nevertheless, as healthy as any of the other centres, but they alone give way, they alone being worried *ab extra*. There is no reasonable doubt that the starting-point is ear disease; these particular paroxysms would not occur even in ill-health unless there were the particular defect, ear disease. I find, however, that some patients consider the diagnosis to be nonsensical. A patient may reply that he has long been deaf, and that he does not care about his ear, that he does not come to you for *that*. (Sometimes, however, he does not know himself to be deaf of one ear.) He evidently supposes you are "thinking too curiously," that you are neglecting obvious causes and explaining the ailment by far-fetched and vague theoretical reasoning. The obvious cause to him is usually stomach and liver derangement; very naturally, for he vomits and may bring up much bile. He cannot see what an old aural affection has to do with a recent sudden paroxysm of vertigo, with urgent vomiting, and great prostration. He would be better satisfied, doubtless, by being told that his attack was due to "suppressed gout," to "liver derangement," etc., for these terms are familiar to him, if the explanations given in them are not really more intelligible. Then he may tell us, in confirmation of his hypothesis, that alterative aperients put him right again, not seeing that, the affection being in its nature transitory, he must come right after a time. What Buzzard says of treatment of batches of lightning pains in tabes dorsalis applies here.[1] I don't blame the patient, although I have to combat his notions. Not many years ago I did not know that ear disease was a cause of the symptoms I have mentioned, and I do not doubt in the least that my then erroneous, but quite conscientious, explanations appeared more rational to my patients than those I give now.[2] You must not suppose that an advance in your knowledge of disease will necessarily make you more fitted to obtain your patient's confidence; it fits you to treat him better, and you must get your satisfaction out of that. If you tell a man who sees perfectly well that he has a grave condition of his optic nerves, he is often the reverse of being assured that you understand his case. The ophthalmoscopical examination which you make, simply because he has intense headache and perhaps vomiting, naturally seems to him quite irrelevant. If you told him that he was suffering from severe biliousness he might be satisfied. He may, indeed, reply to the expression of your opinion that he *knows* it to be "all liver," and, perhaps, may add that he was always very bilious. One great thing you wish to do is to prevent his becoming blind, but if your iodide of potassium makes him "more bilious" very likely you do not see him again. In intense headache we should always use the ophthalmoscope, and if, as very often happens, you discover nothing wrong in a patient's eyes, he evidently feels that he scores one; he *knew* there was nothing wrong with his eyes. Similarly he often *knows* that there is nothing the matter with his heart, lungs, and kidneys, although we are obliged to examine the chest and urine as a matter of routine. If you get to know that hypermetropia is an occasional cause of severe head trouble, totally incapacitating the subject of it for study, you are in error if you suppose that a correct diagnosis founded on such knowledge will always be acceptable to the patient. Very naturally when he finds that, for a time at least, he can read small type, such an explanation of his symptoms appears to him simply absurd. Many of our patients seem to wish to have a conversation on their cases on some basis (gout, liver, rheumatism, etc.), which makes them feel that they follow the doctor in his investigations, and understand his conclusion. They cannot appreciate a scientific medical investigation. If a patient "who knows something of medical matters" consults you for amaurosis (simple optic atrophy), he naturally thinks you are wandering when, after looking into his eyes, you ask about pains in his legs, and then "tap his knees." If you took his view that the lightning pains in his legs were rheumatic, and that his failure of sight was owing to rheumatism of the optic nerves or their centres, he would be more in harmony with you.

---

[1] The Lancet, Feb. 14, 1880.

[2] My attention was first thoroughly drawn to the subject by a masterly paper by Knapp, Archives of Ophthalmology and Otology, vol. ii., No. 1. I gave a short *résumé* of previous opinions on this disease, *Med. Times and Gazette*, Aug. 17, 1872. Charcot has published one of the most important cases of Menière's disease. I have given an account of this in the *London Medical Journal*, April 22 and 29, 1874. A brief account of Ménière's disease is given by Ramskill, in Reynolds's System of Medicine, the first account by a physician in the country, I believe.

Even medical men who have aural disease very often totally reject the proffered explanation of their attacks of vertigo; many of them also ascribe the ailment to digestive troubles. A medical man had deafness of his left ear, with occasional slight vertigo. One day, walking in his garden, he had pain in his head, was very giddy, fell in some shrubs, and vomited. This was plainly ear-vertigo, as he himself knew. But he had had the following diagnoses made of his case by other medical men—(1) Nothing, (2) Nervousness, (3) Deranged stomach.

Be very careful how you interpret acute digestive symptoms. They may be effects, not causes. I imagine that in at least one in five cases of epilepsy the first paroxysm is erroneously put down to stomach derangement. Migraine, unquestionably a nervous affection, is very often similarly explained, and indeed goes under the unfortunate name of "sick headache." Besides, it is very common for cases of fatal brain disease to be explained away in their earliest stages as being caused in this simple manner. It is quite true that as we get older in practice we attach more and more importance to the state of our patient's alimentary system, for plainly our operations are often based on its condition. We always inquire nowadays about our patient's digestion and regulate his diet, whatever ailment he may have, just as we examine his urine, heart, and arteries. But for my part I attach less and less importance to abnormal states of the digestive system as direct *causes* of definite nervous symptoms. Very often there is no other warrant for the diagnosis of liver affection in cases of intense headache, of vertigo, and of transient loss of consciousness, than sickness and vomiting, with the appearance, perhaps, of bile in vomit. If any one from any cause vomits long enough and strongly enough he will bring up bile; indeed, I should take a plentiful supply of bile in the vomit as evidence that the liver was working well. Vomiting is a very general symptom. I mean that it occurs under very many different circumstances —"shock," passage of a biliary or renal calculus, tubercular meningitis, tumour of the brain, migraine, ear disease; then there are the "gastric crises" of tabes dorsalis (Charcot). You do quite right, of course, to note the "stomach symptoms" in auditory vertigo, but you should inquire as to the state of digestion in the intervals of the attacks, when it is often quite good. When the digestion is right in the intervals the "dyspepsia" is paroxysmal, is part of the paroxysm, and no doubt depends on something wrong, not at the stomach end, but at or acting on the central end of the pneumogastric nerve. In a masterly article on "Vomiting in Connection with Cerebral Disease,"[1] Ferrier brings evidence to show that in cases of vomiting from cerebral or any other disease or morbid condition, irritation of the vagus, centrally or peripherically, is the one thing in common to all. I think it is a good piece of work to make a comparative clinical study of the paroxysmal dyspeptic symptoms of migraine, auditory vertigo, and of those in some cases of tabes dorsalis ("gastric crises" of Charcot).

There is, however, described a "stomach vertigo," and as one of the describers of it is Trousseau, we must consider this matter with great respect. If you will read what Niemeyer calls Trousseau's "life-like description" of it, you will find that he does not really make out a strong case. He says that the attacks generally come on long after digestion, that sometimes a small quantity of food prevents an attack or stops it if it has begun, that stomach vertigo does not differ greatly from auditory vertigo, that the "slightest cause" may bring it on, as a sudden movement of the head, or looking at a range of bars, a trellised wall, or a striped pattern in the hangings of a room. I will read an extract from Niemeyer's well-known work. "As above mentioned, Trousseau believes that these attacks of dizziness depend on dyspepsia; at the same time he acknowledges that in many cases the signs of dyspepsia are so slight as to be readily overlooked. He relates cases of the successful treatment of 'vertige stomacale' by the alternate administration of infusion of quassia and a composition of carbonates of the alkalies. Even from this prescription I have never seen any benefit, and while I must acknowledge that the first attacks of dizziness affecting the patients that I have seen usually occurred after an indigestion, and were accompanied by dyspeptic symptoms, still in none of them were there evident signs of indigestion during the subsequent attacks, which often continued for years. I believe the repetition of the attacks of dizziness to be due to psychical causes." Observe how cautiously Niemeyer writes "usually *occurred after* an indigestion," and "were *accompanied* by dyspeptic symptoms;" he does not say "caused by." Curiously, some people deaf of one ear do not know it until it is pointed out to them. Hence Gowers has well said: "The fact that the patient may be unconscious of a most significant auditory defect lessens the value of former observations as evidence of the definite character of stomachal vertigo."[2] I think Gowers will turn out to be right in what he has further written: "My own conviction is that, in the vast majority of the cases in which a vertigo of definite and uniform character is apparently excited by gastric disturbance, an auditory defect will be discovered on careful examination." I confess that I do not believe that a sudden and severe attack of giddiness would occur from dyspepsia, if there were not some flaw elsewhere. Of course, common sense leads us to treat dyspepsia whenever we meet with it; all would agree in this. But we must be careful lest we treat for it when it does not exist; and if there be dyspepsia, we must not neglect to care for other conditions which may not depend on the dyspepsia, or only very indirectly depend on it. I do not deny that ordinary dyspepsia, nor the dyspepsia artificially induced by over-indulgence, may be a factor. I think that dyspepsia, or any other cause of lowering of general health, is a factor in producing or allowing paroxysms both of migraine and auditory vertigo. This was in principle admitted when we referred to Sydney Ringer's opinions. Gowers has put the question very clearly: "In persons the subjects of ordinary vertigo, whose equilibrium nerves and centres are damaged, a primary gastric disturbance seems sometimes to excite a paroxysm of the special vertigo to which they are liable, and the gastric disturbance which thus brings on the attack is naturally regarded as its only antecedent." An admirable observer, Dr. Russell of Birmingham, has described the case of a woman who had symptoms of gastric ulcer and paroxysm of "definite" vertigo, and no sort of ear affection; but he says that "some proclivity in one of the vaso-motor centres, or in some other part of the nervous tract involved, must be presupposed."[1]

---

[1] Brain, Part 6, July, 1879.

[2] Brit. Med. Jour., April 7, 1877.

To return to our special topic. No one need diagnose ear vertigo when there is nothing aural to get hold of. On any view, we should note the presence of ear trouble, if there be any, whether it is accepted as causative or not. This we are bound to do. If any one believes that a patient's attacks of headache are really owing to deranged digestion, he is bound to take heed of any retinal projections there may be in the paroxysms (vibrating air, fortification outline, etc.), and of the mode of their progression over the field of vision. He has to hold his hypothesis, not by ignoring these "definite" projections, but after fully considering them. Then, as Gowers points out, we have to note the kind of vertigo. To use again an expression of his, it is often "definite." Is it likely that when it is so particular that objects appear to be displaced to one side that stomach derangement is the cause of it? Is it not, on the contrary, more likely to be owing to some local lesion in the centres, even if not to disturbance of them by ear disease? And if there were no deafness, it would be rash to say there was no ear disease. I spoke also of retinal projections in some cases of migraine as being "definite." Is dyspepsia or any ailment affecting the nervous system generally likely to be the cause of a migraine with projections creeping over the field from one side towards the other? I entreat of you to inquire into the state of the ear in all cases of paroxysmal vertigo. I am ashamed to confess that I nearly made a very great diagnostic blunder recently by neglecting what I am now urging on you. Of course, you must not put down all paroxysmal affections, even starting with giddiness, as a matter of course to aural affection, even when there is such affection. Some attacks of epilepsy begin by noise in one ear;[2] in some cases of epilepsy and of epileptiform seizures there is organic ear disease, and probably a causative relation. These two kinds of cases differ *toto cœlo* from one another, and each also from cases of Ménière's disease.

I will now recapitulate and also adduce further evidence showing the relation betwixt ear disease and paroxysm, in which there is vertigo with vital symptoms, or in which there is ear disease with a slight and transient vertigo which is often definite. (1) There often is ear disease in the severest cases of vertigo. (2) Often the patient becomes deaf at his first seizure, and remains so afterwards. (3) When deaf of one ear (either before or after his first attack), suddenly turning the head in one direction may make him slightly giddy. (*a*) Thus one of my patients whose ear disease was right was a little giddy when he turned over to the left in bed. He had severe paroxysms also. (*b*) A medical man, whose ear disease is right, tells me in a letter, "The third attack was brought on by a sudden turn from right to left when lying in bed, when the giddiness and confusion lasted for eight or ten days. I have still difficulty in lying on the left side, and could still make myself giddy by turning quickly from right to left when lying. I can turn quite well any way when in the upright position. Auscultating with the right ear a patient lying in bed, the throwing the head to the right is apt to make me a little giddy, this does not occur when the head is thrown to the left." (*c*) Buzzard reports of a patient *subject to paroxysms of auditory vertigo*:[1] "The patient, deaf of the left ear and with noise in it, kept his bed three or four months, unable to turn his head to the left." These facts are, I believe, to be trusted. I must say, however, that the statements of patients as to side of body turned to or side affected in paroxysms of any kind are not to be confidently relied upon. (4) Some patients deaf and subject to attacks may make themselves a little giddy by pressure on the ear. Schwabach reports a case of discharge from the left ear, in which pressure above and below the left auricle caused the eyes to oscillate horizontally to the left side, and slightly downwards—that is to say, the pressure produced a physical condition for vertigo; moreover, the patient felt giddy. I take the following from a paper by Maas:[2] "Of late E. Pflüger observed a case of formation of polypi on the posterior wall of the external auditory canal, close to the membrana tympani. When the polypi were touched with a probe, oscillatory movements in the horizontal direction ensued in both eyeballs." Flourens and other physiologists give oscillation of the eyeballs as one result of experimental injury of the semicircular canals. (5) Syringing the ear in some patients with aural disease produces an attack of auditory vertigo. Every medical man has seen patients thus treated ghastly pale, and reeling. In Schwabach's patient the oscillatory movements of the eyes were repeated in a lesser degree on syringing the ear. (6) Some foreign bodies in the ear produce great misery. I do not know, however, that they produce paroxysms like those of Ménière's disease. You are aware that the pneumogastric nerve sends a branch to the membrana tympani—some say to enable us to hear the dinner-bell. The membrana tympani receives branches from the fifth also. Possibly irritation of the pneumogastric branch is in great measure to blame for such symptoms as occurred in the following case. The case is of some interest; possibly it is a very common one in aural practice. For the notes of it I am indebted to Mr. Lewis Mackenzie, formerly house-physician at the London Hospital:—

---

[1] Med. Times and Gazette, March 8, 1879.

[2] I have published two cases of this kind without autopsy in *The Lancet* of March 11, 1876, p. 386. Recently I have, as Gowers mentions in his second Gulstonian Lecture (*The Lancet*, March 20, 1880, p. 435), had an autopsy in a case of epilepsy, or epileptiform convulsions, in which noise in one ear was the "aura." Gowers examined the specimen for me, and found tumours in the opposite side of the brain.

About 12.30 P. M. on Dec. 30, 1872, John D., aged twenty-two, a strong-built soldier, came into the receiving-room of this hospital in a state of great mental excitement. His face was much congested, the conjunctivæ were suffused, and for the moment it seemed as if he were the subject of a delirium from drink. He was complaining in an excited manner of a "buzzing" in the right ear, and of intense pain, the character of which he could not describe. He frequently repeated that "he would go mad if not relieved." His head rested with his right ear on the palm of his right hand, and it was noticed that he frequently walked round and round, and always from right to left. The house-surgeon had some difficulty in getting him to be quiet, and explain his sufferings. When asked how long he had had the pain, he said since he got out of bed in the morning; in fact he awoke in great pain, "The pain woke me, but has got worse and worse." Whilst I was deliberating as to the diagnosis, the patient said, "It feels like a large insect in my ear." This leading observation at once suggested an examination of the ear. Nothing was seen by ordinary examination, but with an ear speculum and reflected light from a mirror all the tissures appeared healthy, but on more close examination a small black dot was seen at the anterior wall of the tympanum and its junction with the mucous membrane of the external ear, and moving about as if trying to scratch its way betwixt the membrana tympani and the wall of the meatus. One syringeful of water brought out the offender, which proved to be a louse of rather large size, and dark. The patient was *at once relieved*, though his ear still felt "queer." He left the hospital in a state of intense gratitude.

[2] Archives of Ophthalmology and Otology, vol. vii. p. 493.

(7) There are the well-known experiments of Flourens on the semicircular canals, narrated in every text-book of physiology. (8) There are the recent inestimable experiments of Cyon, carrying us a long way further than those of Flourens. (9) There are the researches of Mach and Crum Brown into the functions of the semicircular canals; these researches are of great value; by showing the particular importance of these canals in health they indirectly enforce the opinion that diseases of them may produce definite locomotor symptoms; they are also most valuable contributions to the physiology of the nervous system.

My chief subject is the paroxysm, but there are "chronic" cases. I speak of these to enforce that vertigo and reeling may have a causative relation with ear disease, that not only do "attacks" of vertigo go with it, but that more continuous vertigo does also; in some cases there are both attacks and frequent or continuous reeling. Of course, there is another difference betwixt the two than that of acuteness and chronicity, which, however, for our present empirical purpose, does not concern us. A few persons with ear disease nearly always, or for very long periods, walk unsteadily; they have to walk with attention, and sometimes with their legs too widely apart; they feel slightly giddy; they may walk as if slightly drunk. If the deaf patient comes to you walking well, and yet complains that he frequently is unsteady, you should get him to walk a short distance with closed eyes. All sorts of bad walkings are made worse by closing the eyes, although none so much worse as the gait in locomotor ataxy. I will mention only one case of this kind. I have recorded it in *Brain*, Part 5, vol. ii., April, 1879, partly from notes by Mr. Lewis Mackenzie. It looks to me like a production of chronic vertigo and reeling by experimental injury of one ear. A medical man, after firing a heavily-loaded gun, felt giddy and stunned, and walked badly. Since he has been partly deaf of the right ear, has had noise in it, and has tended to the left side in walking; when arm in arm with some one he would pull or push his companion to the left, according to the arm hooked to. His wife had often to remind him that he walked to the left. He is never without the noise in the right ear. This case is, so to speak, the production of "half a reel" by injury of one ear.

In the case last mentioned there were no paroxysms, but, as already said, there are cases with both severe paroxysms and interparoxysmal slight symptoms. Some patients have strong paroxysms and frequent slight ones. A patient, under the care of my colleague, Dr. Buzzard, besides having strong paroxysms, has what he calls "staggerings" five or six times a day, or even in an hour. He has a feeling of sickness when they come on.

So far we have only empirical evidence of various kinds to show that there is a relation betwixt ear disease and certain nervous symptoms. That there should be is a necessary outcome of very old physiological researches on animals, and of the very recent ones of Cyon.—*Lancet*, Oct. 2, 1880.

MONTHLY ABSTRACT.

Anatomy and Physiology.

Reflex Action in the Vessels of the Eye.

By means of a series of experiments, **Mooren** and **Rumpf** have proved (*Centralblatt für die Med. Wissenschaft.*, No. 19, 1880) that direct irritation of the iris in the rabbit causes injection of the vessels of the eye irritated. and, at the same time, anæmia of the vessels of the fellow eye. This anæmia is followed by injection when the irritation ceases. By repetition of the irritation, it is possible to produce in the fellow eye discoloration of the iris, narrowness of the pupil, and turbidity of the aqueous humour. By the use of ether, anæmia is produced in the eye subjected to its action, hyperæmia in the other; and subsequently a reversal of these conditions occurs as before. The authors conclude that the vessels of the two eyes stand in a close antagonistic relation to each other, and that alterations in the amount of vascular contraction lead readily to inflammation, exudation of white corpuscles, and stasis of lymph. They maintain that the theory which explains sympathetic ophthalmia by reflex action from the ciliary nerves of the one side to those of the other, now rests upon a real and physiological basis.—*London Med. Record*, Oct. 15, 1880.

The Contractions and Convulsions Obtained by Stimulations of the Brain.

Pitres and **François-Franck** (*Travaux du Laboratoire de M. Marey*, 1880) have studied graphically the contractions resulting from the stimulation of the brain. A single electric shock produces, when sent through the motor centre, a single contraction as when the nerve is stimulated. A series of shocks (about forty-five in a second in the dog) produce a permanent contraction. Single shocks, individually too weak to produce contraction, by summation call forth a spasm. Strong stimulation of one hemisphere calls forth contraction on both sides of the body. Stronger currents are necessary to stimulate the white matter than the gray; but the time of reaction is shorter in the former. Tetanus may be obtained by rapid stimulations of the internal capsule (sixty a second), but does not show the same fusion of the individual contractions seen elsewhere.—*London Med. Record*, Oct. 15, 1880.

Galvano-Hypnotism.

Professor **Eulenburg** (*Wiener Klinik*, No 3, 1880) shows that in favourable subjects the supposed hypnotic effects of electricity may be due to many other causes. He describes one case, however, where the galvanic current clearly threw the patient into a hypnotic condition. She was hysterical, with left hemianæsthesia, and was subject to fits of lethargy. The left hemisphere and nerves of special sense were unexcitable by the current; a condition, however, which yielded to treatment and gave place to a galvanic hyperæsthesia. At the same time the passage of the current through the head (negative pole to neck, and bifurcated positive to mastoid processes) was noticed, if kept up for about five minutes, to produce a condition of hypnotism, into which the patient sank not gradually but quite suddenly. Consciousness was quite extinct; some of the cerebral reflexes were much diminished; and gentle stroking of the skin, of the hand for instance, was followed with muscular rigidity of the part, gradually extending over the whole body. The usual means sufficed to arouse her, but a long time elapsed before she had recovered fully her senses. Active continuation of passively induced movements was not observed in this case.—*London Med. Record*, Oct. 15, 1880.

The Effects of the Lightning-Stroke on the Animal Organism.

Professor NOTHNAGEL relates (Virchow's *Archiv*, May, 1880) some experiments he made on rabbits with the Leyden jar. He found that sufficiently powerful sparks produced a localized anæsthesia of transient nature. The extent of the lesion was proportional to the density of the electrical fluid, that is, to its quantity divided by the diameter of the limb. At the same time the motor fibres were temporarily paralyzed, the duration of the paralysis being about the same as that of the loss of sensation. The faradic excitability of the paralyzed nerves was diminished. The author next describes a case where a man was struck by lightning on his right hand, which became completely paralyzed and anæsthetic, and remained so for ten weeks. The recovery was sudden and rapid; in two days the hand became quite well again, and remained so for six years, when suddenly both sensation and motion disappeared from it. Three months after this occurrence, he was admitted into the hospital. He was submitted to the usual electro-therapeutic measures during a few days, but without the slightest benefit. One day, however, it occurred to Professor Nothnagel, who was then experimenting with the magnet on a case of hemianæsthesia, to apply the latter to the paralyzed hand. His astonishment was great on finding that within three-quarters of an hour sensation and motility were returning. Further applications of the magnet were followed by a complete recovery, and a few days afterwards the patient resumed his work. No transfer was observed.—*London Med. Record*, Oct. 15, 1880.

Materia Medica and Therapeutics.

Resorcin as an Antidote.

Professor LICHTHEIM, of Berne (*Correspondenzblatt für Schweizer Aerzte*, July 15), has made researches on the action of this body which indicate that we possess in it a powerful antipyretic, which in several respects is preferable, in regard to the extent and security of its action, to quinine and salicylic acid. If a dose of two or three grammes (30 to 45 grains) of resorcin be given in solution or in substance to a patient in a high state of fever, the first signs of its action show themselves after a few minutes. Giddiness and buzzing in the ears occur, the face becomes reddened, the eyes are brighter than before, the breathing is quickened, and the pulse more frequent by several beats, and generally somewhat irregular. Ten to fifteen minutes after the dose, the skin begins to become moist, perspiration becomes gradually stronger, and after fifteen minutes more the whole body is bathed in sweat. With this outbreak of sweating the symptoms of stimulation which first occur disappear; the giddiness and buzzing in the ears have usually passed off in about fifteen minutes after the taking of the medicine, and a rapid defervescence occurs at the same time with active sweating. The frequency of pulse and the temperature are quickly reduced, and within an hour after the administration of the medicine both have fallen to the normal standard. The secretion of sweat has meantime stopped; the skin of the patient is moist and cool, and his general condition is that of an individual free from fever; the amount of difference of temperature in such cases is about three degrees centigrade (5.4 Fahr.) or more; the frequency of the pulse sinks more than a third. These marked effects are, however, by no means always to be observed. A very great difference in the resistance of fevers to resorcin is to be noted, and here the same rules apply as in the action of the antipyretic agents already known. The less the tendency to spontaneous remissions, the less is the antipyretic effect of resorcin. The fevers of pneumonia and erysipelas are in general more obstinate than that of typhoid fever, and severe typhus in the first stage is controlled by resorcin much less promptly or much less adequately than the mild forms. On the other hand, resorcin does not completely fail, according to Lichtheim's experience, even in the most obstinate fever. Temperature and frequency of pulse fall also in these cases; only the fall of temperature often does not amount to more than one or two degrees (centigrade), and the pulse-beat to a corresponding extent. An unmistakable parallelism exists between the extent of secretion of sweat and the intensity of the defervescence, and the more marked these were, the greater is the fall of temperature.

Although resorcin has advantages over salicylic acid and quinine in respect to the certainty of its action and the extent of its effect, the duration of its action is much less than that of the above-mentioned remedies. Within two hours after its administration, and generally after three to four hours, the temperature begins to rise; and it rapidly ascends to its previous point, the patient meantime complaining of a sensation of cold, which sometimes amounts to a severe rigor. An hour later the temperature and frequency of pulse will be found at the former point, and the general state of the patient corresponding to it.

A great disadvantage of resorcin lies in the preliminary stage of excitement, to which reference has already been made. These symptoms of stimulation show themselves very strongly in a number of cases. Even in the milder forms, morning respiration is often noticeable, together with an increase in the frequency of respiration; and the tardy answers which the patient gives show that he is in a state resembling intoxication. In other cases these cerebral symptoms are much more marked: the patients begin to be delirious, they do not know where they are, they talk wildly, and their expressions indicate that they have illusions; speech becomes sometimes muttering and difficult to understand, and often there is at the same time a slight convulsive trembling of the hands and fingers. One patient fell into a deep sleep, from which he could not be aroused, but from which at the commencement of the defervescence he awoke without any unpleasant symptoms. The latter observation, which is unique, was, however, not made by Lichtheim himself.

All efforts which Lichtheim has made up to this time in order to lessen these collateral effects, without injuring the antipyretic effect of the medicine, have been without result. Even when resorcin was combined with salicylic acid, these phenomena of excitement occurred, although they were not very strongly marked. The effect of a dose of two grammes of resorcin on a patient to whom some hours before two grammes of salicylate of soda had been administered, was one of unusually long duration. According to Lichtheim, this phenomenon of excitement is the only difficulty which opposes the general use of resorcin as an antipyretic, especially in private practice. He especially mentions that an existing albuminuria was not increased by the use of resorcin, and that he has never seen any symptoms of collapse either during or after the administration of resorcin. He rejects the idea with certainty that resorcin can exercise any specific action on pneumonia, erysipelas, or enteric fever; on the other hand, it seems to him to be an antidote to intermittent fever. He refers, indeed, to only two cases. In the first case, a quotidian fever with large tumour of the spleen, after a typical attack, he administered two grammes of resorcin at the beginning of the first premonitory symptoms of fever; only a very slight elevation of temperature occurred, no further attack of fever followed; the tumour of the spleen subsided very slowly, and the patient was allowed to leave at his own wish, with still a very large spleen. In the second case there was also a very old intermittent fever of the quartan type, with a large splenic tumour. The patient had gone through three paroxysms before he began the treatment. Dr. Lichtheim gave, at the commencement of the fourth attack, three grammes of resorcin. The shivering, which had already begun, passed off, but after about an hour recommenced, when two grammes of resorcin were again administered. The subjective symptoms of fever were completely cut down in the patient, although a slight elevation of the frequency of pulse and of the temperature occurred. On the next febrile day the prodromata of fever showed themselves again, but two grammes of resorcin sufficed to cut them short, and the elevation of temperature and pulse was only on a minimum scale. No subsequent attack of the fever occurred.

Together with the moderate price and much more agreeable flavour, resorcin has a great advantage over quinine, in that the administration of the medicine can be postponed to the beginning of the attack, and that, when the dose has too slight an effect, a subsequent increase of it is effectual. In this way any relapse can be prevented before an attack has fully established itself, and on the indication of the well-known prodromal symptoms. In these cases there were not any collateral symptoms, not even the slight cerebral symptoms of giddiness and buzzing in the ears.—*London Med. Record*, Oct. 15, 1880.

Physiological Action of an Alkaloid extracted from the Garden Tulip.

Dr. SYDNEY RINGER has recently been investigating the physiological action of an alkaloid from the bulbs, leaves, and flowers of the garden tulip, and finds that tulipine differs almost entirely from the action of alkaloids derived from the plants belonging to the natural order Amaryllidaceæ so far as he has examined.

Tulipine is a muscle poison, affecting the muscles like veratria. It is, however, weaker than veratria.

It paralyzes either the cord or the afferent nerves, or both; but probably it affects the afferent nerves.

Its action on the motor nerves, if any, is but slight.

It affects the heart of frogs like veratria.

It does not affect the pupil.—*Practitioner*, Oct. 1880.

Therapeutic Use of Pilocarpine in Skin Diseases.

In the *St. Petersburg Medic. Wochenschrift* of July 19th, appears a notice of the results obtained by Professor PICK from the use, over a space of two and a half years, of pilocarpine and its preparations in prurigo, psoriasis, eczema, pruritus, urticaria chronica, alopecia areata, trichoptilosis, alopecia pityrodes, acne, hyperidrosis, pemphigus chronicus, and lichen exsudativus, *i. e.*, in all skin affections where the secretion of sweat is more or less altered. Small doses of one-sixth of a grain in solution were ordered twice a day, one to two hours after food. Perspiration followed generally four or five minutes afterwards. After several weeks' use, unless intermitted, the dose had to be increased. The skin became softer and more pliable, scaliness diminished, and the hair was less brittle. The use of the remedy even for months in no way disturbed the general health. In 32 cases of prurigo the tormenting itchiness disappeared, and the relapses were somewhat delayed; while, again, in 25 cases of psoriasis no effect was seen. In two cases of pruritus senilis, and one of urticaria, a cure was accomplished. In eczema, the result was not decided. In ten cases of alopecia pityrodes, good results followed; while in four cases of alopecia areata, no decisive result was obtained.—*London Med. Record*, Oct. 15.

Physiological Action of Picrotoxine.

CHIRONE and TESTA (*Annali Universali di Medicina e Chirurgia*, April, 1880), after describing the physical characters and mode of preparation of this alkaloid, give the results obtained from a series of sixty experiments. The most important conclusions arrived at are the following: 1. Picrotoxine is capable of causing a true artificial epilepsy. 2. The epilepsy so induced is independent of the psychomotor centres, inasmuch as it is most intense after the removal of those centres. 3. Picrotoxine acts primarily on the bulb and on the commissural fibres between the cerebral and spinal centres, and secondarily on the spinal centres themselves. 4. It demonstrates the existence of a functional antagonism between the psychomotor and motor centres of the bulb and spinal cord. 5. The convulsive movements of the limbs induced by picrotoxine depend primarily upon the action of the drug on the bulb, which is thence propagated to the spinal marrow, and secondarily on its direct action on the spinal centres. 6. In frogs the influence on the spinal functions is more marked than upon the cerebral, while in dogs and the higher animals the cerebral motor centres are the most acted upon. 7. By cinchonoidine an epilepsy of cerebral, by picrotoxine an epilepsy of spinal origin, can be induced.—*London Med. Record*, Oct. 15, 1880.

Anodyne Effects of Electricity.

MÖBIUS (*Berliner Klin. Wochenschrift*, 1880, No. 35) attempts to give a *rationale* of the remarkable effects obtained from this agent in allaying the pain in neuralgia proper, and in numerous other morbid conditions. Numerous authenticated cases, and the daily experience of those who are in the habit of using electricity, show that the pains arising from a variety of organic lesions are frequently allayed by electrization; such, for instance, as those met with in caries of the spine, meningitis, articular and muscular rheumatism, dental caries, uterine derangements, and those known as "headaches," the shooting pains of ataxy, etc. In all these the current acts on the symptom pain only. The author thinks it justifiable to argue from the fact that relief is obtained in a number of dissimilar cases, to the existence of a common feature in those cases. He thinks that electricity relieves pain only inasmuch as it is purely neuralgic, depending upon a molecular condition of the nerve set up by a neighbouring lesion (or idiopathic in the case of true neuralgia). The current, therefore, is a diagnostic as well as a therapeutic agent in the case of pain. As to giving an explanation of how electricity acts in neuralgia, this is impossible for the present.—*London Med. Record*, Oct. 15, 1880.

Medicine.

The Specific Agent of Typhoid Fever.

Professor KLEBS, of Prague, believes that he has discovered the micro-organism which constitutes the specific agent of typhoid fever, and develops his views in a paper entitled "Der Ileotyphus eine Schistomy cose," published in the *Archiv für Experimentale Pathologie*, t. xii. p. 231, 1880. Professor Klebs has for a long time, assisted by his pupils, been making researches in this direction. He writes that he has been able to find, at the necropsy of twenty-four persons carried off by dothinenteritis, microbes in various organs: in the intestinal mucous membrane, in the thickness of the cartilages of the larynx, in the pia mater, in the foci of lobular pneumonia, in the mesenteric ganglia, in the parenchymata of the liver, and generally diffused in the organs which showed the most decided lesions. These micro-organisms showed themselves in the form of rods, about eighty micrometers in length and 0.5 to 0.6 micrometres in thickness. They have been constantly observed in the bodies of dothinenteric patients since the attention of Professor Klebs was drawn to the subject, and they are always absent from the organs, and specially the intestines, of subjects who have died from any other disease than typhoid.—*British Med. Journal*, Oct. 16, 1880.

Successful Treatment at Ben Rhydding of Cases of Chronic Rheumatoid Arthritis.

Mr. FLETCHER LITTLE read a paper at the meeting of the Yorkshire Branch of the British Medical Association at Bradford, on June 16th, in which he described the successful treatment by the aid of the resources of this well-known establishment of several cases of this intractable and most severe disease. They were all cases occurring in women, and all of them were married. One was aged 35, another 51, and the third 67. One had suffered for fifteen months, another for three years, and the third for twelve years. In all, the grating in the joints was most distinct. All were in comfortable circumstances, but they all had gone through severe mental suffering. All showed, by the silvering of the hair, the anxious appearance, and the evident decrepitude, that decay had set in and must be stopped. All of them improved without any drawback from first to last, under patient treatment, oil-rubbing, the galvanic current, and the Russian vapour baths, applied during residence at Ben Rhydding. The patients had been previously treated by Mr. Pridgin Teale, Dr. Merriman, and others.—*London Med. Record*, Oct. 15, 1880.

—

Locomotor Ataxy in several members of the same family.

At a recent meeting of the Clinical Society of London (*Lancet*, Oct. 16, 1880), Dr. GOWERS brought forward a series of five cases of locomotor ataxy in members of the same family, three of whom were exhibited. The father was healthy, but his brother and two half cousins were insane. The mother had suffered in early life from chorea. The family consisted of nine children: (1) A son, aged thirty-nine, with well-marked ataxy, which commenced at nineteen. He is just able to walk with crutches. There is incoördination in the arms and affection of articulation. Sensation to touch is normal, that to pain on the legs increased. The knee-jerk is lost. (2) A girl who died of fever at ten years old. (3) A son, aged thirty-five, healthy. (4) A son, aged thirty-three, healthy. (5) A girl, aged twenty-nine, in whom the affection commenced at eighteen. She can now scarcely stand; there is weakness in the legs, as well as ataxy, and also incoördination in the arms. Speech is affected; sensation is normal; the knee-jerk lost. (6) A son, aged twenty-six, perfectly well. (7) A son, aged twenty-three, considerably affected. The disease showed itself at nineteen; he is now scarcely able to walk, with ataxy of both arms and legs, and loss of sensation, absence of the knee-jerk, and affection of articulation. (8) A son, aged twenty-two, reported to be well, but found, on examination, to be distinctly affected. Articulation is confluent, there is inability to stand with eyes shut, absence of knee-jerk, and distinct impairment of sensation on the legs to touch. The arms are at present unaffected. (9) A son, aged nineteen, affected in rather a greater degree than the last, with slight unsteadiness of gait, inability to stand with eyes shut, distinct impairment of sensation to touch, absent knee-jerk, unsteadiness in writing, and confluent articulation.

The state of sexual power is doubtful, the patients being all single. Thus of eight members of the family who have reached adult life, five are affected, a daughter and four of the seven sons. The symptoms, allowing for the variations in degree, are similar in all, the chief difference being the marked impairment of the tactile sensation in the two youngest, while in the others, in whom the affection has reached a more advanced stage, it is normal, and except that in one there is hyperalgesia. The only causal influence discoverable is the neuropathic heredity.

This form of ataxy was first described as a distinct variety of ataxy by Friedreich, who recorded two groups of cases, and a few other instances have been recorded by Carré and others. Two sisters, evidently suffering from this disease, were shown in 1872 to the Medical Society of London by Dr. A. Carpenter, and in this family a brother has since become affected. Those now shown resemble Friedreich's in the early date of commencement, the affection of the arms, and the interference with speech. They differ from Friedreich's in the number of males affected and in the absence of nystagmus and in the affection of sensation in two individuals. It is noticeable that none have suffered from any pains in the limbs; there is no affection of the iris or of the optic nerve. As in Friedreich's cases, the antecedents were of other forms of nerve disturbances, not of ataxy. The term "hereditary ataxy" seems therefore of doubtful accuracy. Friedreich described the affection of speech as ataxy of articulation, but it does not differ from that seen in other degenerative diseases of the nervous system. The pathological changes were found in two of Friedreich's cases to be in the main similar to those in ordinary ataxy.

Dr. J. ALTHAUS thought that cases of ataxy were more common than usually supposed, and were often confused with paralysis. He had seen more than two hundred cases, but in none of them was more than one member of the family affected, nor could any strict heredity be traced; but in all the cases there was a neurotic tendency observed in one or both parents. Carré's cases were the most remarkable yet recorded. In one instance he states that this form of ataxy was observed in a woman, in her eight children, and in the seven children of one of the daughters—sixteen persons in all—and in three generations. It was remarkable that the pain of ordinary locomotor ataxy was quite absent in this condition, and that the affection of sensation was only slight. He thought that it would be well to follow up the history of those members of this family who were at present unaffected, and also to make careful trial of various therapeutic agents.

Dr. GREENHOW had never seen such cases before; and from the striking facts of the early age of the patients when first affected, and the complete absence of pain, thought that the disease differed from common locomotor ataxy.

Dr. GOWERS had found that ataxy was very rarely to be traced to hereditary influence; he had stated two years ago that fifty per cent. of patients suffering from it had a history of previous syphilis, and he now thought it more accurate to say that such was the case in seventy-five per cent. of cases of sporadic ataxy, in all ranks of society. Apparently the disease is the same in those cases occurring in families, as the posterior columns of the spinal cord had been found to be the seat of degeneration. One of the most remarkable facts is that the disease begins at about the age of twenty, and that any members of such a family who are free at twenty-five escape altogether. So marked a feature is this that a recent applicant for life insurance, who had three brothers and sisters thus diseased, but was himself unaffected and much beyond the age of twenty-five, was recommended by him for acceptance as not being prejudiced.

Visceral Neuralgia.

Dr. Neftel (*Archiv für Psychiatrie und Nervenheilkunde*, Band x. p. 575) describes several cases of recto-vesical and uterine neuralgia, in which every kind of treatment, including that of the organic lesion which was supposed to be the cause of the symptoms, had proved useless. Starting from the hypothesis of a nutritive disturbance of the centres in the spinal cord, he tried the effects of the galvanic current, centrally as well as peripherally applied, with the most happy results. His method in cases of severe dysmenorrhœa is to apply a large electrode (anode) over the genito-spinal centre (Budge's), and close a current of 15 to 20 elements (Daniell's), with a plate above the pubes. A few voltaic alternations are slowly made; then the anode is passed up and down the spine (strong pressure must be exerted), whilst the current may be increased to thirty elements. The same process is repeated whilst the cathode rests upon each inguinal region successively. Relief almost invariably follows such an application. Should this not be the case, higher strengths of current are to be used. A warm drink and sharp walk are advisable after the sitting, which is to be repeated daily during the period. In the time between the monthly paroxysms a milder galvanic course is advantageously pursued towards the accomplishment of an actual cure. Perhaps much depends on the excellent results obtained by the use of a similar method in cases of other visceral neuralgiæ, of congestive and chronic inflammations of the pelvic organs, and also of the central nervous system, on the stimulation of the splanchnic nerves, and consequent extensive vaso-motor effects in the abdominal and pelvic viscera. Dr. Neftel strongly urges the use of galvanism in such cases, and supports his case with good instances. He concludes his paper by showing how a latent malarial cachexia may be unexpectedly brought to light by galvanic application.—*London Med. Record*, Oct. 15, 1880.

Paralysis of Lower Limbs following Pelvic Abscess, or profuse loss of Blood after Abortion.

Mr. William Adams, at a recent meeting of the Medical Society of London (*Lancet*, Oct. 30, 1880) read a paper entitled "Cases of Paralysis with Contraction of One Leg, following pelvic abscess in women; and of both legs following excessive loss of blood after miscarriage." The pathology of these two forms of paralysis with contraction in women is very different; one referring to damage done to the nerve trunks of the sacral plexus by inflammatory exudations, from which only imperfect recovery is likely to occur, and the other to some obscure affection of the spinal cord itself, probably involving slight structural change in the motor tract, from which a good, though not quite complete recovery may occur.

In the *first class* the accumulation of pus in a pelvic abscess, instead of advancing, as it generally does, along the iliac region, and opening through the abdominal parietes, passes backwards and upwards, opening through the rectum or vagina. The nerve trunks of the sacral plexus become imbedded in lymph, which in time contracts, and, so to speak, strangles the nerves, leading to paralysis, with loss of sensation and motion, more or less complete on the affected side, from the hip downwards. The recovery from this condition in the case brought forward has been very imperfect. After a period of four years, the limb only being rendered useful in walking by mechanical support.

In the *second class* the pathology is more obscure. In the case adduced, partial paralysis with contraction of both legs occurred within three weeks of a miscarriage, followed by excessive loss of blood, from which there seemed to be but little hope of the patient recovering. This condition was by some supposed to be the result of "myelitis from loss of blood;" by others, "spinal anæmia." Another suggested explanation was that it depended upon a purely functional derangement. Opposed to the last suggestion, Mr. Adams considered were two important objective symptoms: first, the muscular wasting and general atrophy of the legs; and, second, the peculiar atrophic condition of the skin, which was thin, white, and shiny; predisposed to tear on slight stretching, and corresponding to the so-called "glossy skin" described by Weir Mitchell, Charcot, and Paget as amongst the changes in nutrition of tissues resulting from nerve lesions. The conclusion, therefore, Mr. Adams arrived at was that structural changes had occurred in the motor tract of the spinal cord, from which considerable, though not complete, recovery has taken place up to the present time—six and a quarter years since the miscarriage. The muscles of the hip-joint, and some muscles of the legs, still remain partially paralyzed, but she is able to walk with some assistance. The surgical treatment in the late stage of contraction consists in tenotomy and gradual mechanical extension, either by the use of instruments, or weight and pulley. Forcible extension should never be employed to overcome muscular contraction. With a view of promoting the recovery from the paralysis, Mr. Adams recommended galvanism, shampooing, passive motion, and warm clothing.

Dr. **Allen Sturge**, who had examined the second patient referred to by Mr. Adams, stated that in the right leg there was very marked weakness of the flexor muscle of the thigh and of the muscles of the calf, complete paralysis of the tibialis anticus and extensor proprius pollicis, the extensors of the thigh and the peronei being nearly or quite healthy. In the left leg there was marked weakness of the psoas and iliacus, of the flexors of the thigh and of the calf muscles, the extensors of the thigh and the muscles in the front of the leg being healthy. The paralyzed muscles were almost completely wasted, and their reaction to faradaism was greatly diminished. The condition then was paralysis of groups of muscles in the two legs, with wasting and loss of electricial reaction, without loss of sensation or affection of the bladder—the exact condition seen in infantile paralysis. Dr. Sturge believed, therefore, that the lesion was the same as in the latter disease—viz., acute inflammation of the anterior horns of gray matter in the spinal cord. This condition is now well recognized as occurring in adults, and recently it has been met with as a sequel to typhoid fever and smallpox. May it not therefore occur after parturition or other acute exhausting disease?

Dr. **Althaus** said that the paralysis in the first case was clearly owing to neuritis of the sacral plexus, the inflammation spreading from the pelvic cellular tissue to the nerves. The second case was more obscure, and he discussed the various probable conditions. He discarded the possibility of functional derangement without structural disease. Spinal anæmia occurred after hemorrhage, not only from the womb, but also from the bowels or kidneys, after profuse epistaxis, and occasionally in chloro-anæmia, leading to paraplegia; but it was invariably recovered from under appropriate treatment. Ischæmia of the cord, due to embolism or thrombosis, was clearly not present in this case. There only remained meningo-myelitis, and, looking to the early rigidity, he thought that it probably was a case of pachymeningitis with compression of the cord by inflammatory products, especially of the lateral column.

Dr. **Routh** thought cases of pelvic cellular abscess passing into paraplegia must be rare. He had not met with one in his own practice, and he thought this might be due to his habit of opening these abscesses very early. He related a case he had seen in consultation, where paralysis with contraction followed a pelvic cellulitis; and vaginal examination under chloroform revealed a fibrous mass attached to the sacrum. The copious hemorrhage in Mr. Adams's second case may have been due to a fibroid growth.

Dr. **Edis** mentioned a somewhat similar case, where a lady, having fallen in the street, being four months pregnant, suffered from hemorrhage, retroflexion, and septicæmia. The latter gave rise to much anxiety, although there was no evidence of local pyæmic deposit. Within six weeks from the accident paraplegia, with contraction of the legs and thighs, occurred. This was treated by forcible extension under chloroform and by mechanical appliances, with considerable benefit.

—

A Case of Aphthongia, or Spasm of the Hypoglossus.

Dr. **Mossdorf** (*Centralblatt für Nervenheilkunde*, No. 1, 1880) relates an interesting case of spasm in the domain of the hypoglossus (with associated spasms of some respiratory muscles), in which the ordinary treatment for stammering had failed to produce any permanent good. Galvanization of the head and phrenic nerves was persevered in for two months without any result, but the application of strong galvanic currents with the anode at the occiput, and the cathode labile along the spine, produced within a week a marked improvement. Several short courses of this treatment at intervals have brought about what seems to be a permanent cure. The author contrasts this result with that obtained in a case of stammering from spasm produced by irritation of the right facial nerve after a blow. In this case faradization and galvanization peripherally applied failed, but the continuous current sent through the cortical centres effected a speedy cure.—*London Med. Record*, Oct. 15, 1880.

—

Treatment of Dyspepsia.

M. **Damaschino** (*Le Progrès Médical*, May, 15, 1880), defines dyspepsia as a morbid state characterized by slowness and difficulty of digestion. This definition, so uniquely symptomatic, is very accurate, for dyspepsia is only really a symptom either during the evolution of a gastric affection or in the course of or subsequent to a general malady. The etiology of dyspepsia is very varied, for age, sex, temperament, habit, and certain diatheses exercise a marked influence upon the development and course of the digestive trouble. In this way the varied symptomatic forms which are observed in this pathological condition are explicable, as well as the inefficacy of the most rational methods of treatment which is so often noticed. Amongst the numerous remedies for dyspepsia, the digestive ferments, and of these more especially pepsin, occupy the foremost place. To enable these remedies to act with certainty they ought to approximate as closely as possible to the conditions under which they act in the natural state; by the union of pepsin with hydrochloric acid a very soluble digestive ferment is obtained, which is found to possess an exceedingly energetic action; in combination with pancreatin, coca, and bitters, which increases its eupeptic action, it forms the basis of the elixir of Grez. This preparation acts not only by its own digestive properties, but also by stimulating the secretion of the gastric juice, so that it is also a peptogen. A great number of experiments have been conducted in the French hospitals, in regard to the use of this elixir in the treatment of intractable cases of dyspepsia, with a result that there has been a rapid improvement of the general condition, with a complete remission of all the symptoms, pains, gastric meteorism, eructations, and vomiting. Affections connected with stomachal vertigo, and migraine arising from functional impairment, have been rapidly cured. Digestive troubles also, which are so frequent in adults, and more especially at puberty, as well as in chloro-anæmia, have invariably yielded to the influences of this remedy. Phthisis is nearly always complicated with dyspepsia, often in the form of obstinate vomiting, which rapidly aggravates the condition of the patient; in such cases the elixir has afforded the most excellent results by curing the vomiting and altering the state of the alimentary canal. Rheumatic and gouty patients, who for a long time previously had digested with difficulty, have recovered their digestive functions after a few days of this treatment. Lastly, this elixir has been employed at the Children's Hospital in numerous cases of chronic diarrhœa and vomiting with the very best results, and it has even been used with success in that most severe and dangerous of the affections to which children are exposed, infantile cholera.—*Practitioner*, October, 1880.

On Alcohol and Creasote in Infantile Diarrhœa.

In the infantile diarrhœa of infants artificially fed, Dr. **Demme**, of Berne, is not content with prescribing breast-milk, but recommends alcohol in conjunction with benzoate of soda or with creasote, after the following formula (*Journal de Med. et de Chir. Pratiques*): Cognac, 2 to 5 grammes; creasote, 0.1 centigramme; pine tar, 1 to 5 grammes; distilled water, 50 grammes every twenty-four hours between the sucklings. In very young babies the quantity of alcohol—at first two grammes—should be gradually increased to five grammes. The object of this draught is at once to stimulate nutrition, and to check the too abundant formation of the micrococci which load the intestinal glands.—*London Med. Record*, Oct. 15, 1880.

The Treatment of Bright's Disease.

In the medical clinic of Genoa during the scholastic year 1877–8 (Virchow's *Archiv*, Band 80, Heft 3), the quantity of urine and albumen, the other chief phenomena, and the influence of various methods of treatment, were ascertained in six cases of Bright's disease. For a certain number of days a fixed method of treatment was adopted, and then a change was made in another subsequent number in favour of another method, in order in this way to study the activity of the various modes of treatment. Professor **De Renzi** arrived at the following conclusions: 1. When chronic Bright's disease is left entirely without treatment, in general no improvement is shown; hence this must be excluded from the category of those diseases which in many cases end in spontaneous recovery. In the first days after entering the hospital, or when the treatment is purposely left off, the patients show a considerable quantity of albumen; this rule has, however, some exceptions which have not up to the present time been well explained. 2. Fuchsin, which has lately been recommended in the treatment of Bright's disease, produces a remarkable diminution in the quantity of albumen. It was employed in two forms: dissolved in water, or, mixed with a suitable extract, in pills of 2½ centigrammes each. As, however, the strong coloration of the infusion of fuchsin in water is somewhat repulsive, Dr. De Renzi found it preferable to administer it in the pill form, and to this he has adhered in his latest prescriptions. 3. The daily daily dose of fuchsin may be much greater than that in which it has hitherto been recommended in the treatment of Bright's disease. Dr. De Renzi generally began with a very small dose of 5 centigrammes (0.75 grain), raising it to 25 centigrammes (3.8 grain), to be taken in twenty-four hours. A considerable physiological action on the principal functions of the body was observed. According to the dose of fuchsin, the urine began sooner or later to show a red colour, which maintained itself throughout the treatment. 4. The urine in Bright's disease often exhibits a great deal of mucus. Fuchsin is very useful against this complication, as, in a short time, it causes the complete disappearance of the mucus from the urine. 5. The mucous membrane of the digestive tract is deeply coloured by fuchsin, and the blood-plasma undergoes considerable coloration. In two cases, the quantity of hæmoglobin and the chromometric state of the blood were examined with Bizzozero's instrument with the following results: *Maria Molinari*: Cytometric state, 160; Hæmoglobin, 68.7; Chromometric state, 175. *Theresia Gabella*: Cytometric state, 115; Hæmoglobin, 29.7; Chromometric state, 112. It is evident that the increased intensity of colour is not to be ascribed to the increase of hæmoglobin, but rather to the increase of the fuchsin in the blood. 6. When fuchsin does not pass into the urine, this is an indication of an organic disturbance which must not be neglected. In these cases, it is of no use in the treatment of albuminuria. 7. Rest of the patient in bed is a very important means of diminishing the albuminuria in Bright's disease. In a patient, *Vittorio Rossi*, complete rest in bed, together with milk-diet, brought about the greatest diminution of the albumen in the urine. Dr. De Renzi was several times able to ascertain that unusually active movement of the person had a dangerous effect in Bright's disease. 8. Apomorphia was in general well tolerated; and Dr. De Renzi has ordered it in larger doses than usual (viz., 5 to 6 centigrammes daily) without causing the least disturbance. In one case, this medicine considerably improved the condition of the patient.—*London Med. Record*, Oct. 15, 1880.

On the Treatment of Intraperitoneal Rupture of Hydatid Cysts.

At a recent meeting of the Académie de Médecine (*Le Progrès Médical*, 1880, p. 426), M. Féréol read a paper on the subject, in which he stated that in the present condition of our knowledge it is impossible to say exactly what circumstances determine the comparative mildness or malignity of the symptoms which accompany rupture of hydatid cysts into the peritoneal cavity. The following conclusions, however, may be stated with some degree of confidence. 1. Previous suppuration of the cyst gives rise in case of rupture to a subacute rapidly fatal peritonitis, at least where the peritoneum had not been sealed by adhesions which limits its inflammation. 2. The penetration into the peritoneum of an absolutely limpid and clear fluid, which appears to be inoffensive in some cases, is followed in other cases by rapidly fatal accidents. 3. The presence of living hydatids thrown into the peritoneum is less dangerous than that of dead hydatids: spontaneous cure is possible in the former case. 4. In cases where the peritonitis following rupture becomes moderated, and where, nevertheless, ascites is produced, intervention may be practised with some hope of success if the ascitic fluid be not absorbed. Simple puncture is alone sufficient to effect a cure. If this procedure fail, it may become necessary to evacuate the foreign bodies contained in the peritoneum as soon as possible. A large opening may be made into the abdomen by a trocar, and cleansing out of the peritoneal cavity twice daily may be employed with success.—*London Med. Record*, Oct. 15, 1880.

Glycosuria.

According to modern theories, diabetes is supposed to depend, to a large extent, perhaps entirely, upon derangement of the vaso-motor mechanism of the liver. This point in the pathology of the disease has been the subject of a recent series of investigations by M. Laffont, which have been published in the *Gazette Médicale de Paris*. Claude Bernard, as is well known, showed that division of the cord between the seventh cervical and first dorsal vertebræ arrested the effects of the "diabetic puncture" of the floor of the fourth ventricle, and hence concluded that the path of the nervous influence was by the splanchnic branches of the sympathetic, and that the glycosuria is the result of an irritation, not of a paralysis, of the nerves, since the latter would not be removed by a second division of the path. M. Laffont has endeavoured to ascertain the truth of this opinion, by stimulating the first dorsal pair of nerves by faradization, and observing the effect of this stimulation on the vessels of the liver. In the first series of experiments he opened the spinal canal, and divided the cord at two spots, isolating a segment corresponding to the first and second dorsal pairs. He next exposed the liver, and observed changes in its vascularity by the naked eye. The observations were made upon dogs. On irritation of the isolated segment of the cord, the liver was observed to present disseminated congestion, accompanied by a corresponding injection of the intestine, and turgidity of the spleen. The view that the morbid influence is irritative rather than paralytic is thus confirmed.

Bernard also found that the stimulation of the central extremities of the vagus increased the amount of sugar produced; while Bezold ascertained that similar stimulation caused, in curarized animals, a fall in intra-arterial pressure, which, Ludwig and Thiry showed, was due to dilatation chiefly of the abdominal vessels. Vulpian attributed this effect to the simultaneous stimulation of the central extremity of the depressor branch of the vagus. M. Laffont has endeavoured to ascertain whether this latter view is correct, and he found that intermitting stimulation for an hour of the central extremities of the depressor nerves, by means of a weak faradaic current, produced actual glycosuria, the sugar amounting to from twenty-five to forty-nine grammes per litre of urine. This fact had, indeed, been already ascertained by Filehne, who stated further that the faradization of the central extremities of the pneumogastrics themselves in the rabbit does not cause glycosuria. The latter fact is not corroborated by Laffont. He was able by such stimulation to cause a glycosuria amounting to from eight to seventeen grammes of glucose per litre, and believes that it is due to the asphyxia produced by this stimulation.

In another series of experiments it was found that painful stimulation of any mixed nerve, frequently repeated, caused glycosuria at the end of a certain time, amounting, in different animals, to from four to nine grammes of sugar per litre. Next, the effect of division of the first two or three pairs of dorsal nerves on the glycosuria resulting from puncture of the floor of the fourth ventricle was investigated in rabbits. Threads were placed around the roots of the first two dorsal pairs, and, the effect of the diabetic puncture having been ascertained, the nerves were torn through by means of the thread. The effect was that the sugar fell from twenty and forty grammes per litre to seven or twelve grammes. The effect of this operation on the vascular phenomena caused by stimulating the central portions of the pneumogastric or depressor nerves was then examined. It was ascertained by means of a canula introduced into the carotid or crural artery. In the dog, the stimulation of the central extremities of the pneumogastrics with a strong current caused always an enormous increase of pressure, while feeble stimulation produced, on the other hand, a considerable diminution of pressure. The roots of the first three or four dorsal nerves were then torn through, and after this the feeble stimulation, which had before caused a fall in the blood-pressure, produced a considerable rise. The result was the same in the rabbit, with the exception that a strong stimulation of the depressor nerves never caused an increase in the blood-pressure. Thus the separation of the dorsal nerves prevents the effect upon the circulation otherwise caused by the stimulation of the pneumogastric or depressor nerves.

What is the effect on the abdominal circulation of stimulating the peripheral extremities of the upper dorsal nerve roots? Since all the roots could not be simultaneously excited, the first pair only was stimulated, the animal being under the influence of curara. A fall in the blood-pressure resulted, not considerable in degree, because under the influence of curara there is already dilatation of the abdominal vessels. The pressure was estimated in the splenic artery, or in one of the branches of the mesenteric artery. It was thus ascertained that the stimulation of these nerve roots by a weak faradaic current caused always a fall in the arterial pressure in the abdominal organs if the root is carefully isolated. The least extension of the current to the spinal cord itself caused an increase of pressure.

The conclusions drawn from these experiments confirm the view that the glycosuria which results from the stimulation of the central extremities of the pneumogastric nerve in the dog, the depressor nerves in the rabbit, and the sensory nerves generally, is the results of an impression conveyed to the bulbar vaso-dilator centre, the path from which is by the cervical cord, the first dorsal nerve roots, and the sympathetic and splanchnic nerves. It is conjectured to be by an action upon this centre that certain cardiac and general diseases may cause glycosuria. These effects, and those of the diabetic puncture, are prevented by the separation of the upper dorsal nerve roots, while the effect of stimulation of these divided roots shows that they contain dilator nerves for the vessels of the abdominal viscera.—*Lancet*, Oct. 23, 1880.

Melæna Neonatorum.

Dr. J. Halliday Croom, Physician to the Royal Maternity Hospital, Edinburgh, records (*Med. Times and Gaz.*, Oct. 23, 1880) four cases of melæna neonatorum, which are of interest on account of the rarity of the disease and of the obscurity of its pathology. Dr. Croom remarks that it is at the outset necessary to draw attention to the fact that melæna neonatorum, as generally understood, is of two kinds, melæna vera and melæna spuria. With the latter (melæna spuria), where the blood does not come from the stomach or gut, but either (*a*) from other parts of the child, mouth, nose, lungs, or (*b*) from the nurse's breast,—the present communication has nothing to do. The cases that I now record are cases of melæna vera.

Case 1.—In May, 1870, I saw with a dispensary pupil a child, five hours after a normal, easy birth, suffering from "bloody diarrhœa." The child, which was to all appearance a perfectly healthy male at term, had passed when I saw him about a teacupful of dark, treacly-looking matter; and about an hour after the first, another equally copious motion passed, which on examination proved to be almost entirely blood. The action of the bowels was evidently unaccompanied by any pain. The infant became cold, vomited a small quantity of milk, and afterwards about a desertspoonful of pure blood. During the succeeding twelve hours the child had six motions. The first five were mixed with blood; the last was scanty, and contained only meconium. During and shortly after each motion the infant became cold, motionless, and seemingly exhausted by the hemorrhage, but between the attacks became more lively, sometimes cried and took the breast. The child made a perfect recovery. Decadence of the cord took place on the sixth day without hemorrhage. While discussing the case with my pupil, he incidentally told me that the father of the child had come to the dispensary the previous week to have a tooth extracted, and that during the night the man had sent for him to have the bleeding stopped, because it had continued to faintness. The man, aged thirty-four, was fair and slender, but in vigorous health. As a boy he said that he had frequently suffered from epistaxis, and that even in adult life he had been more than usually subject to bleeding from the nose. He had

had three (including the present) teeth extracted, and after each there had been an unusual loss of blood. He had never any wound or bruise so far as he remembered, and no swelling or affection of the joints. The mother had given birth to three children, all of whom had died in early childhood of diseases having no bearing on the present subject. She could give no history of any unusual tendency to hemorrhage in herself or any relative.

Case 2.—On the morning of January 10, 1875, an apparently healthy male child, extracted by forceps owing to rigidity of the soft parts, was, six hours after birth, seized with a copious discharge of dark blood per rectum. When summoned, the woman in attendance stated to me that the first two motions from the child were natural, that when the blood passed the child evinced no sign of pain, and she did not know anything unusual had happened until she examined the napkin. I saw the napkin; it contained coagula and stains sufficient to correspond to, say, a claret-glassful of blood. The child seemed well, cried vigorously, and moved its limbs freely. Four hours after the first there was a second and more profuse discharge of blood, and within half an hour a third, less severe, however, than either of the former. I saw the infant shortly after the last hemorrhage; the extremities were cold, the face blanched, pulse hardly perceptible, and the child lying motionless and collapsed. Small quantities of brandy were ordered, and warmth to the extremities. The child remained much the same till midnight, when it cried feebly, and passed a scanty but otherwise normal stool. In the early morning there was a slight return of the hemorrhage. During the following day the child gradually improved, took the breast, and from that time onwards made a complete recovery. Decadence of the cord was unaccompanied by hemorrhage. In this case forceps was applied to hasten a delivery protracted by rigidity of the soft parts. Very little compressing or extracting power was required. Shortly after birth the child·presented blotches on either side of the head, involving the cellular tissue behind the ear, the posterior part of the external ear, and the scalp over the parietal bone. The blotching was more marked on the left than on the right side. The ecchymoses, as they seemed to be, disappeared on the fifth day, and were evidently the result of the pressure, slight though it was, exerted by the forceps. The infant died three months afterwards from diarrhœa, but no post-mortem could be obtained. Both father and mother were of phthisical descent. I could trace no tendency to bleed in the parents or in their families.

Case 3.—After a labour extending over seventeen hours, Mrs. S. A., multipara, was delivered of a small but healthy male fœtus, at term, without artificial aid. Ten hours after birth I was asked to see the child, whom I found pale, blanched, pulseless—in fact, moribund. The woman in attendance told me that during the day it had passed quantities of blood by the bowel. I was shown the napkins, and found them soaked with blood. Except the first napkin all the rest were stained more or less with blood, some of them saturated. The child died shortly after I saw it.

Sectio Cadaveris.—Rigor mortis well marked. Lungs and heart were healthy, but the substance of the heart was very pale. The whole intestinal tract was carefully examined bit by bit, but no trace of any ulcer, abscess, or erosion, either in the stomach, duodenum, or any other part of the gut, could be discovered. There was in the lower parts of the bowel some slight congestion along with several clots of blood. There was no enlargement of spleen. All the organs were extremely pale and exsanguine, but healthy.

Helmbrecht relates a case somewhat similar to this, where a child a few days after birth died from bloody diarrhœa and vomiting of blood. Congestion of the rectum was the only morbid condition found on post-mortem examination.

Case 4.—An infant, three weeks old, hand-fed, was suddenly, during the night, seized with profuse dark diarrhœa, accompanied by occasional vomiting of blood. I was summoned in the morning, but the child had died an hour previous to my visit. On inquiring of the nurse, I was told that on the previous evening the child was apparently quite well. During early morning the child was seized with what appeared to be diarrhœa. The nurse was, however, struck with the dark colour of the stools, and on examination found them to consist almost entirely of blood. During the night there was considerable vomiting of blood. I requested a post-mortem examination. This was granted, and the section was performed by Dr. Illingsworth, one of the demonstrators of anatomy in the University, who made the following report: Pericardium contained about a teaspoonful of serous fluid. Heart normal; valves competent. In the aorta was found a post-mortem clot partially decolourized. Septum ventriculosum normal. Fossa ovalis ventriculi empty. Right auricle filled with a firm clot; left auricle contained firm clots. Lungs slightly congested at their base, more especially the right lung. No embolism found in any of the branches of the pulmonary artery. Bronchi filled with glairy mucus. Stomach normal. Duodenum—capillary injection of mucous membrane, especially of upper two-thirds, but no sign of ulceration. Rest of intestine and other organs normal, but pale.

It is not my intention now to enter into any description of the symptoms or treatment of this disease. The symptoms are plain—a discharge of blood from the bowel, either with or without hæmatemesis. The treatment in such early infant life amounts to *nil*. I wish rather to draw attention to its pathology.

The rarity of this affection has not had any effect in limiting the suggestions which have been advanced to account for it; on the contrary, they have been both numerous and varied.

Billard[1] ascribes the condition to a follicular inflammation of the stomach and bowel. Bouchut[2] divides bleeding from the intestine during early infant life into three groups—first, from purpura; second, from passive congestion, the result of compression at birth; third, as a result of acute or chronic inflammation of the stomach.

Rilliet and Barthez,[3] after discussing the probability of the hemorrhage being the result of compression at birth *ab* plethora of the veins of the abdomen, discard these as causes, and suggest that heredity plays an important part in the disease.

West[4] says that in the greater number of cases the occurrence has taken place within a few days, sometimes within a few hours after birth, and in some instances has followed a tedious labour, in which the head of the child has been much compressed or otherwise injured during attempts at extraction, while in other cases the difficulty in the establishment of the respiration has seemed to be the predisposing cause of the hemorrhage. Very often, he adds, no reason can be assigned for it.

Braun[5] suggests a variety of causes which may account for melæna—congestion of the mesenteric vessels, pressure during birth, heredity, intra-uterine interference with nutrition.

Gerhardt[6] draws attention to the extreme rarity of the affection, but throws little or no light on the pathology.

[6] Lehrbuch der Kinderkrankheiten. Tübingen, 1871.

Steiner[1] says that the round, perforating ulcer is a very rare thing in infancy, but has been met with by Billard and others in the new-born. He thinks it due to fatty degeneration of the arteries, and its special symptom is described as melæna neonatorum.

In an elaborate monograph on the subject, Landau[2] reviews the pathology of melæna. He passes in review the many extravagant hypotheses that have been suggested as explaining this rare and little understood affection. He then comes to the more recent views of Hecker, Buhl, and Spiegelberg.

Hecker and Buhl base their statements on two post-mortem examinations which revealed the existence of abscesses respectively of stomach and duodenum. Hecker, however, does not suggest any cause for the abscess.

Spiegelberg made two post-mortems on children who died from this cause, and in both he found abscesses in the duodenum. He is of opinion that their origin is intra-uterine. Landau reports two cases of mælena, both of which were fatal, and in both of which careful post-mortem examinations were made. In both, abscesses of the duodenum were found.

Landau comes to the conclusion that nearly all uncomplicated cases of melæna which occur in otherwise healthy new-born children depend on material changes in the stomach and gut—*ulcis ventriculi sive duodenum rotundum*, upon rupture of an artery or a vein. Unlike the authors to whom I have already alluded, he thinks these ulcers do not depend on fœtal inflammation of the stomach, nor are they of intra-uterine origin. He believes that they arise in connection with occurrences at birth causing derangements of the circulation, very often by a small embolism, either secondary or primary, arising from pressure and restraint of the first inspirations.

In the few cases recorded by Landau, in which careful post-mortem examinations were made, there can be no doubt that the perforating ulcers he so minutely describes were the cause of the hemorrhage and death. His suggestion as to the embolic origin of the ulcer is a valuable and ingenious contribution to the pathology of the disease.

This explanation does not, however, hold true of the majority of the cases of melæna. The greater proportion recover. Barthez and Rilliet[3] alone make mention of twenty-two cases, of which twelve recovered. This would hardly be the result in cases of ulceration sufficient to give rise to hemorrhage to the extent mentioned; and again, in many of those cases—notably those of West—in which post-mortem examinations were made, no morbid change could be found in any of the abdominal viscera. In these latter, therefore, ulceration, whether the result of embolism or not, could not have been the cause of the hemorrhage.

I am inclined to think that in the cases I have recorded we have indications at least of the direction in which we are to look for some, perhaps of most, cases of melæna.

In the first case it has been shown beyond doubt that the hemorrhagic tendency was well marked in the father, not certainly to the length of being a marked case of hæmophilia, but sufficiently to show the tendency to bleed. In the second case, although no tendency to bleed could be traced in the parents, still the fact that the ecchymoses, so extensive, occurred on either side of the child's head as the result of but very slight pressure by the blades of the forceps, seems to show that the child had a marked tendency to hemorrhage from very slight causes. Even in extreme cases of contraction at the brim, where great compressing and extracting power has to be used, frequently no mark further than an indentation from the blades of the forceps is to be seen. Apart, then, from the melæna, this child had a tendency to bleed.

---

[1] Steiner's Diseases of Children, translated by Lawson Tait, p. 237.

[2] Ueber Melæna der Neugeborenen, von Dr. Leopold Landau. Breslau, 1874.

[3] Op. cit.

In Cases 3 and 4, although no reliable family history of bleeding could be obtained, and although the child showed no indication of a tendency to hemorrhage other than the melæna, yet the fact that the post-mortem examination gave no trace of any morbid condition save patches of slight congestion here and there in the intestinal canal, leaves the suggestion as to a diathetic tendency to bleed a feasible one.

In these four cases at least a hereditary or congenital tendency to bleed, either spontaneously or on very slight provocation, would seem to be the pathological explanation of the condition. It is true that in only two of the four cases had I an opportunity of making post-mortem examinations, the result being that no morbid condition could be found. This, however, I consider to be rather confirmatory of my view than otherwise, because it is an ascertained fact that in those who are the subjects of hæmophilia, and in whom death has occurred from extensive hemorrhage, no morbid change can be found, nor any single point discovered to account for the bleeding. Again, if the pathology of hæmophilia consists, as has been shown by Dr. Wickham Legge,[1] in an imperfect development of the whole vascular system, so that the fœtal state—not, of course, of the circulation, but of the vascular walls—remains in extra-uterine life, it seems to me probable that the pressure exerted on the child during birth, the establishment of circulation and respiration, combined with the active movements of the child's body, may give rise to hemorrhage from the thin-walled capillaries along the intestinal tract.

But, apart from physiological exciting causes such as those I have just mentioned, any cause interfering with the respiration will occasion increased pressure on the venous system and render the tendency to hemorrhage more marked. Now, other causes are exceedingly common at birth, such as tedious labour, aspiration of mucus, as well as the pressure of instruments. In two of my cases such causes were, no doubt, factors in the production of the hemorrhage.

Beyond being occasioned by ulceration of the gut, or as a general oozing from the capillaries, which I believe to have been the fact in the cases I have just recorded, or from venous congestion the result of obstructed respiration, melæna vera may be caused by[2] rupture of a vein, polypus of the gut, or perforation from round worms.

In looking at the sex of the children affected, Barthez and Rilliet[3] find girls more subject to it than boys. Landau[4] also points out that the affection is more common in girls than in boys. Barrier[5] groups twenty-one cases, of which twelve were girls and nine boys. Of my own four cases three were boys and one a girl. There can be no doubt, however, that of the recorded cases the majority were females. Now, this will be pointed out as an argument against my suggestion, that the cases we are now dealing with are cases of early development of hæmophilia, because it is admitted that boys are more subject to hæmophilia than girls. In fact, in the earlier accounts of hæmophilia, girls were supposed to be entirely exempt. A glance at Lange's paper,[6] in which are collected all the then (1849) published cases of hæmophilia, shows that there were 227 or 229 boys to 31 girls. Grandidier[7] showed 452 boys and 31 girls.

[6] Lange: Oppenheim's Zeitschrift, Bd. xliv. p. 157.

[7] Grandidier, Die Hämophilie, page 87. Leipzic, 1858.

Now, it is worthy of remark, that of the recorded cases of deaths from round perforating ulcers, all, without exception, were girls—*e. g.*, cases recorded by Spiegelberg and Landau. This is only in accordance with what is found in adult life, where ulcer of the stomach is more common in women than in men. If we therefore withdraw from our calculation the fatal cases, many of which in all probability depend on ulcers either of the stomach or duodenum, we shall have the balance of the sexes more nearly equal, and therefore render the suggestion of hæmophilia feasible enough; and in my own cases the question of sex does not enter at all, as, of the four cases, three were boys and only one a girl.

The period of early infant life at which melæna usually occurs varies considerably, but it is generally within one or two days after birth. In the majority the symptoms develop between the first and sixth days. Of fifty cases, collected from various sources, I find that the hemorrhage took place—in thirty, between the first and sixth day; in eight, between the sixth and eighth day; in four, between the eighth and twelfth day; in eight, between the twelfth and eighteenth day. Of the first thirty cases, six developed within the first twenty-four hours.

In regard to prognosis, Landau points out that there is no record of a cured case of gastric or duodenal ulcer in a new-born child. The cases which recover are those which owe their origin to some of the other causes of which I have referred. Taking the cases altogether the mortality is about 60 per cent.

The diagnosis of melæna is simple—the discharge of blood per orem or per anum, or both—but the exact diagnosis of the cause is altogether another matter. If the melæna occur after a difficult labour, or when there has been difficulty in establishing the respiration, then venous congestion or rupture of a vein may probably be credited with the cause, or it may be an early symptom of hæmophilia. If the melæna take place shortly after a normal labour in an otherwise healthy child, especially if any hereditary tendency to bleed can be traced, the cause will probably be found in a condition of the vessels similar to that found in hæmophilia. If the melæna occur profusely several days after labour, if there has been any interference with respiration, and if the case be fatal, the cause may be looked for in a gastric or duodenal ulcer, originating, as Landau shows, in an embolism.

Surgery.

Notes on Chian Turpentine, and its Use in Cancer.

Dr. John Clay, Obstetric Surgeon to the Queen's Hospital, Birmingham, publishes in the *Lancet* (Oct. 2, 1880) the following additional article on this subject which has of late attracted so much attention.

In the correspondence which has been recently published in the medical journals the efficiency of Chian turpentine in the treatment of cancer has been altogether denied by certain writers. Some have suggested that unsuccessful results may be attributed to the impurity of the drug employed; others have ungenerously questioned the validity of the statements made in my paper, which appeared in the *Lancet* for March 27, 1880. It consequently seems advisable to offer some further general observations, by way of explanation and elucidation, on the subject.

It is a matter for regret that the supply of the genuine Chian turpentine has been so limited, as this has led to the substitution of factitious drugs, the use of which, as I have previously explained, unfavourably influences the results, besides entailing the further disadvantage of preventing a thorough testing of this method of treating cancer. I believe it is a fact that Chian turpentine, in mass, can scarcely be procured in this country at the present time, and therefore it is obvious that the treatment of the disease must be somewhat in abeyance until a supply of the pure drug arrives from abroad. I hope that the difficulty will soon be overcome, as I have been making special efforts to obtain the pure turpentine direct from Scio, and have had three excellent samples of the genuine drug sent to me through the post from that island; a supply may therefore be expected shortly, when the purity of the drug at least will be definitely determined. The specimens referred to differ in some particulars from the Chian turpentine which I have previously described, and which had been in stock some years. There are also samples of larch turpentine in the market, which slightly resemble the recently gathered genuine drug. It may be of advantage therefore to the profession to describe each, and to note their differences.

Specimen No. 1 is of a pale, amber colour, and almost entirely free from impurities. It has the fragrant odour peculiar to Chian turpentine well marked, which is readily perceptible after rubbing a small portion between the thumb and finger. It has a mild terebinthinate taste, which rapidly disappears. On placing a small portion of the drug on a piece of glass, and exposing it to the atmosphere, it considerably thickens after a few days' exposure.

Specimen No. 2. This, obtained last year, is the drug as collected. It contains a large quantity of foreign matter, such as pieces of bark, sand, etc., all of which give it a darker colour than the last-mentioned specimen. Two ounces of this crude product yielded, after straining, upwards of half an ounce of impurities. The strained portion contained still a quantity of minute particles of foreign substances. The taste and odour are the same as in the Specimen No. 1.

Specimen No. 3 resembles soft glazier's putty, but is somewhat whiter, and is of the same consistence. It is Chian turpentine that has been well washed in water, to free it from impurities. It has a mild taste of turpentine, and the peculiar odour is well-marked. If a portion is subjected to pressure between two pieces of glass, water can be readily forced out of the mass.

Three specimens have been submitted to me as genuine Chian which were purely larch turpentine. They may, as alleged, have been gathered in Cyprus. They have a strong odour of pine wood, and are of a browner appearance than the recent specimens just described. On tasting a portion, it appears tasteless for the first minute, after which a strong, bitter, nauseous flavour became manifest, eventually leaving a strong, sickening sensation at the back of the throat, which is slow to disappear. A portion placed on glass, and exposed to the atmosphere for four weeks, showed no signs of thickening, and readily adhered to the fingers.

The degree of solubility of the two kinds of turpentine, in ether and alcohol, is not materially different from that described in a former paper. The mild terebinthinate taste of the pure drug, its peculiar odour, with its power to solidify on exposure to the atmosphere, are characters sufficient to distinguish it from any other turpentine resin.

The results of the treatment of various forms of cancer, in the hands of certain medical practitioners, are alleged to be so different from those obtained by myself, that these gentlemen have thought fit to question the validity of my experiments. Certain results obtained by the use of a remedy, almost forgotten by the therapeutist, were placed by me unreservedly before the profession; and for the benefit of suffering humanity at least a fair trial of the remedy ought to be given before condemning it. In testing the efficiency of the drug, it is doubtless all-important that the true one should be used. It would appear to be not an easy matter to decide the question of purity, for upwards of three hundred specimens have been sent to me for examination by English and foreign medical men, most of them being guaranteed by the druggists supplying them, and it was a surprise to me to find so few examples of the genuine article amongst them. It will be as necessary now as before to use extreme vigilance in this respect in expectation of the new supply. In a large percentage of cases the factitious turpentine only has been used in the treatment of cancer. In one institution this was particularly so; and after the genuine drug had been tried for about three weeks the results of the two were combined, and a letter forthwith appeared in *The Times*, alleging that the remedy was useless. A similar instance occurred in an institution in this town, where the impure drug was first used, and then after a trial with the pure drug for about three weeks, letters appeared in a medical journal declaring that the remedy was of no benefit in the treatment of cancer. It is plain that sufficient time has not been allowed to elapse for the full effects of the remedy to be manifested, as in these instances of condemnation it has almost invariably been declared inoperative after a few weeks' trial only. Besides the unsatisfactory results which have accrued from the use of the impure drug, the full effects of the pure turpentine have not been gained in some instances from the drug not having been entirely digested. This has arisen occasionally from its incomplete preparation for administration. In compounding the mixture, freshly prepared mucilage of tragacanth, B. P., has not been used, and then it rapidly decomposes; or sufficient of the mucilage has not been employed, which causes the resin to separate, and the doses of the medicine, therefore, have been irregular and insufficient. It has been shown in the *Pharmaceutical Journal* that acacia powder might be advantageously substituted for the tragacanth. It is necessary, therefore, to provide that a sufficient quantity of either gum shall be used in the preparation of the Chio turpentine mixture.* Where the digestive powers are impaired, an addition of twenty minims of the compound tincture of cinchona to each dose has occasionally proved beneficial. The discontinuance of the sulphur has been advised, in order to make the mixture more elegant and miscible. I believe, however, that the mixture is more efficient, when it is well tolerated, if prepared with the sulphur.

In reference to the pills, if they are not properly prepared they are not always digested. If this is discovered on examining the evacuations, the use of the mixture in conjunction with the pills is indicated; that is, a dose of the mixture should be taken by the patient night and morning, and two pills in the middle of the day, in each case after food. It is advisable, when commencing the treatment, to give only half doses of the turpentine for the first week. Magnesia should not be used as an excipient in the preparation of the pills, but whether this exception ought to apply to the recently collected drug future experiment will have to decide. Pills prepared with magnesia are almost insoluble, and the same remark applies to some coated ones. The pills may be prepared sometimes with ether, to soften the turpentine, or it may be made soft by immersing the mortar in a hot-water bath, the sulphur being added to the mass in its softened state. The latter mode appears preferable, if only to facilitate the digestion of the pills, as if any difficulty is met with in this way they may be roughly powdered and taken in milk or some bland liquid, and then they are generally digested.

The statements made in my original paper as to the efficacy of Chian turpentine in cancer appear to me to be fully confirmed by the additional experience gained in the use of the remedy. In the cases previously reported the cancer has disappeared, and there are no signs of its return. This fact must be considered at least as a complete refutation of the statements, recently and boldly made, that Chian turpentine in the treatment of cancer is useless. The cases just referred to are unique of their kind, for, so far as I know, they are the only instances on record of cancer being cured solely by the administration of an internal remedy

I feel justified, therefore, in stating that uterine cancer at least may be removed by the use of Chian turpentine.

It is a fact which might be expected that most of the cases of cancer which have presented themselves are in an advanced stage of the disease; and more especially is this the case in cancers of the uterus. Yet the treatment continues to be very efficient. My experience does not stand alone in this respect, for several gentlemen have given independent testimony of the good effects produced by the turpentine treatment in cancer of various organs. In my original experiments the turpentine alone was used in order to thoroughly test its efficacy, but it now appears that the use of certain local and general measures undoubtedly promotes the convalescence of the patient. It is possible, therefore, to formulate a line of treatment which shall be successful in cancers of the uterus. Hence, given a case of cancer limited to that organ, and a steady use of the remedy for six or eight months, continued with certain general and local remedies if necessary, and a disappearance of the cancer may be reasonably expected. Eleven cases of uterine cancer under this treatment at the Queen's Hospital, besides a number of others in private practice, so far justify the preceding statements. Some very interesting facts have been observed during their treatment, which I hope to detail on a future occasion.

It is advisable not to be too precipitate in rejecting a case of uterine cancer on the ground of its being too far advanced for treatment. The following case, amongst others, is to the point. Mary B. took her discharge from the Middlesex Hospital, London, about four months ago, and, according to report, was informed that her case was incurable, and that she had not long to live. She had heard of the turpentine treatment, and was very anxious to be under my care at the Queen's Hospital, but I advised her not to undertake the journey, as I believed the case, from what I heard of it, was too far advanced for treatment. This advice, however, she disregarded, and became an in-patient at the Queen's Hospital. Here she was placed under the Chian turpentine treatment, and improved so much in nine weeks that she is about to return to London with every prospect of soon being cured

In cancer of the uterus the conclusion expressed in a former paper, that the remedy destroys the cancer cells and causes the death of the growth, is strengthened by experience, and, as a consequence, there is cessation of pain and hemorrhage in the first instance. But the turpentine at first does not destroy the bloodvessels of the part. As the dead tissue escapes, these become denuded, and give rise to hemorrhage, especially at the menstrual period. In patients who have past the climacteric period this has not been observed. Ergot has been found of no benefit in arresting the hemorrhage. Insufflation with three grains each of sulphate of zinc and powdered charcoal, once or twice a day, after syringing the vagina, has proved effectual, and appears to promote the obliteration and atrophy of the vessels. The same end may be attained by using a weak solution of perchloride of iron and glycerine. I have ordered some patients to syringe the vagina daily with equal parts of common vinegar and water, with good effect. When the anterior walls of the vagina are involved, either primarily or from extension, the case is not so suitable for treatment with the turpentine. A vesico-vaginal fistula is soon generally formed, but if this do not happen, cystitis supervenes, and the patient succumbs to the uræmic symptoms which are rapidly developed. Moreover, the turpentine is not well tolerated, but when a fistula forms, it is better borne, and uræmia does not arise.

Excision of the cervix uteri is not advisable, as the disease readily extends to the anterior wall of the vagina subsequently; and then the bladder complications, above described, arise with increased force. The use of the curette is not so objectionable if it is employed to remove only the sloughing mass after some weeks' use of the Chian turpentine, but it has not been deemed necessary to use the instrument, it being all important to preserve as much normal tissue as possible.

The mode in which Chian turpentine effects the removal of cancer was well illustrated in a case of epithelioma of the vulva. The patient, aged sixty, had been operated upon for cancer of the clitoris or vulva. The case was reported in the *Lancet* at the time. The patient thoroughly recovered from the operation. About a year afterwards cancer reappeared in the lower part of the vulva and vagina. The growth was again excised, and she made a good recovery this time. About eight months afterwards a cancer appeared on the right labium, and when it was there seen for the first time it was the size of half-a-crown. It was determined to give the Chian turpentine, and the drug was given in full doses three times daily. At the end of the first week there was no alteration, excepting that the cancer was thought to be somewhat paler on its surface, and the surrounding swelling less. Second week: The growth was coated with a secretion of a grayish colour, which appeared to be firmly adherent. Fourth week: The growth was only half its former size. Its surface was somewhat convex; and was considerably thicker than previously, and was surrounded by a ring of a bright crimson colour. One of the resident surgeons of the hospital who saw it remarked that it looked like a small mushroom springing from the vulva. Sixth week: The growth was now diminished to the size of a fourpenny piece, and was still surrounded by the bright coloured ring, but was free from the secretion. The surface did not bleed on being touched. Eighth week: The coloured ring had disappeared. The growth was much smaller, and it had the appearance of a large "seedy" wart, such as is sometimes seen on the hands. Tenth week: The growth remained about the same. Twelfth week: The growth had all but disappeared, and the patient went into the country for a short time, but promised to report herself when she returned.

In private practice three cases of cancer of the rectum are under treatment, two of which are much improved; and one has not been seen again, but a favourable report is given after seven weeks' trial. Three cases of cancer of the stomach are under treatment; one has discharged herself, but the other two have remarkably improved, as regards freedom from pain and capacity of retaining nourishment, though continual sickness existed previously. So far as the treatment has extended, these cases seem to prove that the turpentine is equally, if not more, efficient in cancer of the stomach than of any other organ. In one case the glands of the neck were much enlarged; but these swellings entirely disappeared after the use of the remedy. Four cases of cancer of the tongue have been under observation. In one case the growth was as large as a cherry, and in four weeks it was reduced to a level with the mucous membrane, and it appears now to be cicatrizing.

Several cases of cancer of the face have been very much benefited. In two cases of endothelial cancer of the abdomen and one of cancer of the liver, no benefit seemed to be derived, excepting that in one case there was some alleviation of pain, and an improvement of general health for a time.

In all forms of cancer, where the turpentine has been taken for six or eight weeks, I have found the administration of a tonic to be of advantage, as it promotes the convalescence of the patient, and if the disease affects the uterus or rectum it seems to facilitate the escape of the débris from the destroyed mass, and to promote cicatrization. Four minims of the tincture of perchloride of iron, and three minims of liquor strychniæ, taken three times daily, are recommended; and if there be any pain, which often happens after six months' use of the remedy, six drops of tincture of belladonna are added. A generous diet is allowed.

Morphia is not advised. The bowels should be kept daily moved, when necessary, by a mild aperient. After the turpentine has been regularly taken for three or four months, I now recommend it to be discontinued for three or four days in the fortnight. It is probable that future experience will show that, after it has been taken for the above-named period, it will be no longer necessary in the majority of cases, but as a precautionary measure it has been generally continued in the manner just described.

There are sixteen cases of cancer of the breast under treatment in the hospital, and a large number are under observation privately. The effects of the remedy in the first few weeks are, the relief of pain, and a diminution in the size of the breast, which is generally more movable, even when apparently fixed to the walls of the chest; this probably arises from a diminution of the surrounding cancerous infiltration. Time has not been sufficient, however, to speak with definiteness as to the ultimate results. The clinical facts brought out in this class of cases are very interesting and instructive. There is a great probability that the disease is arrested, as after four months' trial of the remedy the morbid growth has not increased in size. As far as can be stated at present, for therapeutical purposes the cases appear to be divisible into three classes: 1. The ordinary scirrhus of the breast, with or without surrounding infiltration. 2. Epithelial cancer. 3. Cases of ulceration after previous operation.

In the *first* class of cases great interest attaches to the experiment, as indicating how the solid mass is removed. It appears at present to deport itself as if it were a foreign body, and seems disposed to make its way rapidly to the surface; but in the cases where this has occurred the growth is not of an active character, for as the mass comes to the surface a crust forms upon it. This disappears in time, and another forms, while the whole bulk of the mass gradually diminishes in size. It may prove eventually that this is one mode of the removal of the disease. In these cases the growth does not increase in size, but, on the contrary, gradually diminishes.

In the *second* class—*i. e.*, epithelial cancers—the surface of the growth becomes paler at first, then smoother, as if it had been levelled by friction; sometimes some of the nodules slough away. Then a process of cicatrization takes place. There are two cases in which the new tissue around the growth is quite half an inch in breadth. Two others, about one and a half and two inches respectively in diameter, have entirely healed over.

In the *third* class of cases the results are so far favourable that the ulceration has not increased in size, but they have not progressed so favourably as the other cases. In several instances the glands of the axilla have been enlarged, but the enlargement has generally disappeared under a steady use of the turpentine.

The importance of these imperfect notes to the profession, and the influence they may have in aiding the treatment of cancer will, I hope, be a sufficient apology for reverting to the subject. At least I trust I have shown that the remedy is not useless. I may, in conclusion, state that in the treatment of these diseases patience and perseverance for a few months are absolutely necessary. In some diseases which affect the human race, a continued treatment for twelve or eighteen months is often thought requisite. It has, I believe, been here shown that the remedy does produce some influence on the progress of cancer; and it is but reasonable to require that a similar indulgence be extended to the treatment of cancer by this method, as in the chronic diseases just referred to. As the remedy can be taken with impunity for a long period, and if time be granted for the trial of it, I feel that I am justified in stating that its steady use promises excellent future results.

Partial Tenotomy of the Muscles of the Eye.

Dr. **Abadie**, in the *Annales d'Oculistique* (May, June, 1880), urges, in certain cases of insufficiency of the internal recti, a partial tenotomy of their antagonists. He bases this teaching on von Graefe's doctrine, and recommends the revival of the method of partial division of the tendon, which that great master actually performed in one year as many as 120 times. Dr. Abadie has himself, of late frequently performed the operation with very satisfactory results. His procedure is as follows. The first stage of the operation is the same as that for ordinary strabismus: the hook is passed under the tendon of the muscle, and any slight hemorrhage at once restrained, for the operator must have a clear view of the tendon. The tendon is then snipped across about half-way, with sharp pointed scissors, commencing at the free border of the hook. A similar incision into the tendon is made in a direction towards the handle of the hook, a few tendinous fibres being left adherent to the sclerotic. In the last eight months, Dr. Abadie has performed this operation ten times, with the result of relieving asthenopia, due to insufficiency of the internal recti, in cases where prisms had completely failed. The great advantage of the treatment, according to the author, is that it is prophylactic, and can be applied at a very early stage, so soon, in fact, as any insufficiency of the internal recti becomes evident; that is the proper treatment to check the onset of those pathological changes which characterize progressive myopia. Once such changes as thinning of the membranes of the eye, atrophy of the choroid, lesion of the macula, and finally, detachment of the retina have supervened, treatment is powerless. [In an able note appended to this paper, M. Giraud-Teulon combats the author's conclusions, and points out that he has adopted von Graefe's earlier views, forgetting altogether that von Graefe himself abandoned partial tenotomy after an experience of ten years; and in his latest writings insisted on the necessity of a complete division and detachment of the muscle from its sclerotic attachments.—*Rep.*]—*Lond. Med. Record*, Oct. 15, 1880.

Choroiditis as a Sequel of Relapsing Fever.

In the *Klinische Monatsblätter für Augenheilk.* (Jan. 1880) Dr. **Julius Trompetter** reports that, in three hundred and twenty-five cases of relapsing fever in Breslau, twenty-one cases of choroiditis were observed; they were mostly of the acute form. On admission to hospital, the patients mostly presented the characters of well-marked choroiditis in the form of cyclitis. Very frequently hypopyon appeared, in the absence of inflammatory phenomena on the part of the iris. Turbidity of the vitreous humour was ascertained in all the cases; and the visual acuity was always considerably impaired at the commencement of the illness. The field of vision showed a limitation of the periphery in all directions. The course of the choroiditis was in general favourable; its average duration was from a month to six weeks. In two cases, both eyes were affected. Dr. Trompetter believes that the affections of the eye in relapsing fever are due to embolism arising from partial necrosis and abscess of the spleen.—*British Med. Journal*, Oct. 30, 1880.

Emphysema from Inflation of the Tympanum.

Professor **Voltolini** relates the following case of the above accident which he has recently met with (*Monatsschrift für Ohrenheilkunde*, May, 1880). Mr. H., aged 28, suffered for several years from progressive deafness without definite cause. The watch was not heard with the left ear, and on contact only with the right. The auditory canals and membranes presented nothing abnormal. On catheterizing, air passed into the tympanic cavities with a very weak stream. The finest bougies (India-rubber with olive-shaped ends) could only be introduced with difficulty, on account of either some narrowing or bending of the tube. Larger bougies were gradually introduced, with decided benefit to the hearing. One day, on inflating the right ear with the bag, after one of the thicker bougies had been passed, sudden pain in the throat was experienced, and emphysema could be felt extending to the lower part of the larynx on the right side and also above the larynx on the left side. No bad effects resulted from this On the left side only the thinnest bougie was employed, but, in spite of this, one day, whilst air was being blown in with the bag, the patient jumped up suddenly and tried to spit something up out of his throat. On inspection, the uvula was found blown out with air into a white bladder. This was immediately relieved by a few snips with the scissors. The author thinks that this case speaks strongly against the use of the condensing-pump for inflation, which, if employed in this case, he supposes might have produced sudden death by emphysema in the larynx. —*Lond. Med. Record*, Oct. 15, 1880.

Gastrotomy for Establishing a Gastric Fistula.

DR. CARL ELIAS, of Breslau, in a contribution to the *Deutsche Medicinische Wochenschrift*, No. 25, 1880, points out that gastrotomy, performed for the relief of carcinoma of the œsophagus, has hitherto been almost invariably attended with bad results. Whilst in some few instances in which a gastric fistula had been established for the relief of symptoms caused by impermeable cicatricial stricture, the patients survived in good health for many months after the operation, similar treatment in instances of carcinoma of the œsophagus has always been followed by death within a period of three months. In most of the forty instances of gastrotomy performed for œsophagus carcinoma during the past two years, the patient died in the course of a few days after the operation. The author then proceeds to discuss the question whether, in the face of such results, it will be prudent for surgeons in future to attempt to establish a gastric fistula in cases of cancer of the œsophagus. An analysis of the cases in which gastrotomy has been performed shows, the author states, that very few of the patients died from acute peritonitis consequent on the operation. Since the introduction of the antiseptic method, and also in consequence of recent improvements in the method of fixing the stomach to the edges of the wound in the abdominal wall, the risks of acute peritonitis as a result of gastrotomy have much diminished. The statistics of recent ovariotomy prove that operations on the abdominal cavity have been attended with much less danger since the introduction of Listerism. The author, in order to show that very severe operations may be performed on the stomach under antiseptic conditions without exciting peritonitis, refers to a case in which he attempted to excise a cancerous growth at the pylorus. In this case, although the whole of the stomach had been drawn out through an incision in the abdominal wall, the patient subsequently remained quite free from fever and lived until the twentieth day after the operation, when death occurred simply as a result of the disease. In most of the cases of carcinoma of the œsophagus in which a gastric fistula was established, the author believes the operation had been too long postponed, and the patients died in consequence of exhaustion and slow starvation. If it be recognized that gastrotomy for establishing a gastric fistula is a safe operation when performed with antiseptic precautions, and that good and plentiful nourishment is one of the main therapeutical objects in cases of carcinoma of the œsophagus, then it must be allowed, it is argued, that the surgeon is not only justified in performing the operation in cases of such disease, but is bound to have recourse to such proceeding at as early a stage as possible, and to establish a gastric fistula before the patient's strength has been reduced to a minimum and the cancerous disease has far advanced. The irritation of the diseased parts by the passage of food is thus removed, and the patient's mind is thus relieved from the fearful prospect of death from starvation. Lumbar colotomy, performed for the relief of the symptoms of rectal cancer, is now a recognized operation, and in cases of acute laryngeal stenosis tracheotomy is often performed for the sake of euthanasia, and notwithstanding the probability of speedy death from diphtheria or croupous pneumonia.

One of the most important points in the operation for establishing a gastric fistula, is the secure attachment of the anterior wall of the stomach to the edges of the incision in the anterior abdominal wall. Unless care be taken in applying the sutures, there is a risk, during vomiting or coughing, of the stomach being separated and slipping far back into the abdominal cavity. The author prefers for this part of the operation an interrupted suture of tough and firm material, involving, on the one hand, a broad piece both of the serous and the mucous coats of the gastric wall, and, on the other hand, the whole thickness of the abdominal wall, including the peritoneum. This is sufficient to retain the empty stomach in position until it has contracted firm adhesion to the parietes. It is unimportant whether the material of the suture be silver wire, catgut, or silk, and equally so whether the wall of the stomach be incised immediately, after the application of the suture or subsequently, after an interval of some days, when the parts have contracted firm adhesion. The author reports a successful case of gastrotomy for establishing a gastric fistula. The patient, a male, aged 46, first experienced difficulty in deglutition in May of last year. This symptom gradually increased, and in November the man was unable to swallow solid food. During the interval he had suffered from occasional attacks of pain in the back and right shoulder, and in October deglutition of small masses of solid food was followed by cough, nausea, and vomiting. From the commencement of the present year he became weak, and rapidly lost flesh. Dr. Elias saw the patient for the first time in February, and, after exploration of the œsophagus, diagnosed an annular carcinomatous structure in the lower third of the canal. In spite of the daily introduction of the œsophageal tube the structure progressively contracted, and at the end of May it was found impossible to pass any instrument through which fluid food could be introduced into the stomach. Gastrotomy was then performed with attention to all antiseptic precautions, save the use of the spray. Much difficulty was experienced in finding the stomach which was very small and not distinguishable from intestine, until after free exposure both of the viscus and of the mesentery with the gastro-epiploic vessels. During the application of numerous sutures of stout carbolized silk, the stomach was retained near the surface by two long needles passed at right angles to each other through the anterior walls of the viscus. During the first four days after the operation the patient suffered very much from pain in the epigastric region, and from almost intolerable sensations of hunger and thirst; but, after incision of the gastric wall and final establishing of a fistula, on the fifth day, he progressed favourably, and ultimately, with regard to the operation, made a good recovery. When last seen by Dr. Elias, the patient was able to walk about, his pulse and temperature were normal, he reported the conditions of his life to be tolerable, he had been relieved of the dread of dying from starvation, and there was a good prospect of his living for some time.—*Lond. Med. Record*, Oct. 15, 1880.

On the Incision of the Kidney—Nephrotomy; and on the Extra-peritoneal Removal of the Kidney—Nephrectomy.

W. **Heineke** contributes, to Von Pitha and Billroth's "Handbook of Surgery," the following interesting article on Nephrotomy and Nephrectomy—two operations which have been performed of late, and have attracted considerable attention.

After referring at some considerable length to the literature of the subject, and quoting the now well-known opinions of Hippocrates, Riolan, Rayer, and others on the advisability and practicability of incising the kidney, Dr. Heineke goes on to say that towards the end of the seventeenth century the thought arose with surgeons to shorten the sufferings of patients afflicted with stone in the kidney by extirpating the kidney entirely. This idea was suggested by the results of experiments made on dogs by Zambeccarius, who, having succeeded in removing the spleen of a dog, next proceeded to cut out the kidney. Stephen Blancard repeated the experiment on the dog with success, and several surgeons who saw the operation were of opinion that the kidney in man could be removed entire after ligaturing the vessels. Rayer, thinking only of the removal for renal calculi, condemned the operation because he thought the diseased kidney would be so closely adherent to the peritoneum that it could not possibly be removed without fatal injury to that structure. But the question of nephrectomy reached a new stage when G. Simon, in 1869, successfully performed the operation for the cure of a fistula of the ureter, after convincing himself of the feasibility of the operation by repeating the earlier experiments of others on dogs.

Dr. Heineke first confines his remarks to the indications for the operations, and, secondly, goes on to describe how the operations are to be performed.

Indications.—The incision of the kidney, *i. e.*, nephrotomy, aims at opening the pelvis of the kidney so as to empty it of its pathological contents. Such an evacuation is desirable and necessary if the pelvis of the kidney contains calculi, or if it is expanded by pus or urino-purulent fluid. In the normal condition of the kidney, the pelvis is covered by the substance of the kidney in such a way that it is not possible to cut into the pelvis of the organ through a lumbar incision without incising the excreting structure. An incision through the substance of the kidney, owing to the great vascularity of the organ, leads, however, to considerable bleeding, which, as in the case of accidental injury of the kidney, may easily become fatal. Nor is it easy to check hemorrhage from the kidney through the depth of the wound. The incision into the pelvis of the kidney must therefore never be made through the substance—at least, not as long as this part of the organ is in a normal condition.

In cases, however, in which the pelvis of the kidney is required to be opened, it is frequently possible to reach it without penetrating the substance of the kidneys, owing to the cyst-like distension of the whole body of the organ. The kidney being thus changed, the operator, after making the lumbar incision, has before him a renal cyst, which is recognizable by distinct fluctuation, and as the dilated pelvis spreads over the edges of the hilus of the kidney, he can readily reach the thin cyst-wall. Not unfrequently, too, in those cases in which the renal substance forms part of the limits of the cystic dilatation, this substance is so atrophied, and the bloodvessels so few and small, that only a thin layer, and that not very vascular, has to be cut through in order to reach the contents of the pelvis of the kidney. In such cases, an incision penetrating the renal substance will not induce dangerous bleeding.

The incision of the kidneys from the region of the loins is indicated for the purpose of removing calculi or pus or urino-serous effusions if the pelvis of the kidney can be opened without causing perilous injury to the substance of the kidney; and, as just stated, this possibility exists when the pelvis of the kidney is considerably dilated.

If calculi are present in the pelvis of the kidney they frequently excite pyelitis, and this leads to distension of the pelvis of the kidney with pus. From other causes also, such as catarrhal inflammation of the bladder and consequent blockage of the urine, as well as exanthematous affections, pyelitis may arise and gradually lead to considerable dilatation of the basin of the kidney. In cases of this sort pains exist in the region of the kidney, which now and then become vehement; sometimes vomiting occurs; the urine contains a purulent sediment, and has a mostly acid reaction; there is fever and occasionally rigours, and often a very high temperature in the evening. If the pelvis of the kidney contains calculi, attacks of renal colic and blood and gravel in the urine are additional symptoms. In cases of suppurative nephritis without the presence of gravel in the urine, attacks similar to renal colic due to stone sometimes occur as the result of obstruction of the ureter from polypi.

After these symptoms have existed for a long time the suppuration reached to the substance of the kidney, abscesses form in the cortical parts of the kidney until the whole organ is turned into an abscess-cavity. By the escape of the pus from this renal abscess into the tissues surrounding the kidney, deep-seated abscesses in the loins arise, which break through in the direction of the back, burrow into the pelvis, or empty themselves into a neighbouring cavity. The longer the process exists, the less prospect is there of a spontaneous cure; and the patients decline gradually on account of the suppuration and hectic, and die at last of debility or of septicæmia or pyæmia. In such cases the incision of the kidney may be of avail; it ought to be proceeded with if the suppuration and consequent debility increase, or if the patient is troubled by frequent renal colic, as soon as a painful fluctuating swelling can be detected by palpation in the region of the kidney through the abdominal wall, or by the rectum. If stones are found in the pelvis of the kidney after it is opened they are to be extracted.

If the symptoms of pyonephrosis are present, it is advisable to cut into the swelling, even if fluctuation be not yet distinct. If a cystic expansion of the pelvis of the kidney can be felt and reached from the lumbar wound, it must be opened. If there be an abscess in the substance of the kidney, then this too should be incised. If through the lumbar incision a perinephritic abscess be disclosed, it will be judicious to search with the finger or a probe for a sinus which may be leading into the pelvis of the kidney or through the secreting substance, and if such be found it will have to be dilated.

In cases of hydronephrosis, if the sac of the kidney has become very large, so as to be close to the front wall of the belly, it is better to open the tumour through the lateral part of the front of the abdomen than through the loin; but should the symptoms necessitate an opening being made at an early stage of the hydronephrosis, the incision through the loin must be had recourse to. The same rule also applies to cases of pyonephrosis.

The extirpation of the kidney—nephrectomy—can only be undertaken if the other kidney still performs its functions properly. It is indicated in cases of hemorrhage from the kidney threatening to be fatal; in suppuration of the kidney likely to become lethal through exhaustion, putrefaction, or pyæmia; in calculous disease of the kidney, if not curable by incision of the kidney; in cases of new growths of the kidney; and in cases of fistula of the ureter not curable in any other way. The hemorrhages which occur after injuries to the kidneys are not infrequently so considerable that the patient may succumb to the bleeding alone. After injuries which have been caused by some contusing power, and where there is no external wound, the hemorrhage is more easily stopped, because the clots which accumulate in the kidney close the vessels by the pressure which they exert. Even bleeding from the chief branches of the renal artery is not apt under these circumstances to continue long; hence it very seldom happens that subcutaneous injuries of the kidney cause death through hemorrhage; and such injuries have been observed, even after lasting and repeated hemorrhage, to terminate favourably.

It is different with the injuries of the kidneys caused by stabs, blows, cuts, and gunshot wounds. In these cases the blood can escape outwardly, and there is not the same tendency to check it by the accumulation of clots; and therefore the danger of hemorrhage from the kidney is considerably greater, the blood escaping through the outer wound as well as through the ureter. Should bleeding in such cases continue, and all other means fail, nothing remains but to ligature the vessels at the hilus of the kidney; and as this proceeding would cause the death of the kidney, the extirpation of the kidney must be added to the ligation of its vessels; or rather, it is necessary to begin by detaching or separating the kidney, and one must ligature its vessel as the last step of the removal, for the ligation of the vessels is scarcely practicable before detaching and drawing outwards the kidney. When in a case of severe bleeding there is danger in the delay, Simon has advised not to wait to detach the kidney from its surroundings, but to proceed at once to the hilus, and ligature the vessels; and not till then to complete the extirpation of the kidney. It is doubtful, however, whether more time is not lost in this procedure than in ligating the vessels after detaching the kidney from its surroundings; on the cadaver at least the latter proceeding can be more quickly performed than the former.

Extensive and protracted suppuration of the kidney which threatens to cause death, either through the fever of suppuration or through pyæmia, demands the extirpation of the affected organ. In many cases, it is true, the incision of the kidney will suffice, especially when the suppuration has settled essentially in the pelvis of the kidney, and has caused considerable expansion of the same, as well as in cases of large abscesses of the substance of the kidney which lie close beneath the renal capsule, and which are accessible through an incision in the loin or through an existing wound. Extensive suppuration in the kidney and its surrounding tissues renders the complete removal of the diseased organ necessary. This form of suppuration occurs especially after injuries to the kidney, whether compound or subcutaneous. On the other hand, idiopathic pyonephritis in most cases, if there be need of any operation at all, may be cured by the incision of the kidney; but the operation of extirpation is generally impracticable, because both kidneys are affected by the disease.

Extirpation of the kidney was undertaken by Von Bruns in 1871, for dangerous suppuration following a gunshot wound of the kidney. The kidney could not be entirely separated, as it had formed considerable adhesions; the pedicle was therefore tightly surrounded with a ligature, and the convex half of the kidney taken away. The patient died at the end of ten hours.

Renal calculus has already been mentioned as an indication for the incision of the kidney. The incision is, however, only practicable when there exists an expansion of the pelvis of the kidney in the shape of a bag. If the pelvis is only slightly expanded the incision of the kidney cannot be undertaken on account of the reasons discussed above. In such cases radical relief can solely be expected from extirpation of the calculous kidney. This operation is nevertheless of such danger as not to be underrated; and it is doubtful whether nephrolithiasis is such an important affliction as to justify one in undertaking a very dangerous operation on account of it. In cases in which the calculus frequently causes renal colic, and in which there is also suppuration of the kidney, from time to time associated with fever, it cannot be doubted that an operation, even attended with danger, for the removal of the disease, is permissible; as the suffering not only tires out the life of the patients, but also diminishes their faculties and threatens their existence by chronic suppuration, extension of the disease to the other kidney, or by the obstruction to the excretion of urine. It has been feared (Rayer) that the kidney affected with stone would become so adherent to surrounding tissues, and especially to the peritoneum, that it could not be removed without perilous injuries to other parts, but the experience of Simon is opposed to this view. Another argument against extirpation arises from the difficulty of making an accurate diagnosis of the disease. Gunn (1870) was on the point of removing stones from a kidney, which he considered in that way diseased, by means of an incision. When, however, after exposing the kidney, he could feel no stones through its substance, he desisted from the operation. A similar thing happened to Durham. The latter surgeon undertook two years later, in the case of the same patient, whose disorder had returned, the extirpation of the kidney in question. The kidney, however, was proved to be normal. Peters extirpated a kidney which he considered diseased by stone, but which was proved to be tuberculous. These cases show how easy it is to be mistaken as to diagnosis in regard to nephrolithiasis. But it follows from Simon's experience that it is also a mistake to think that stones contained in the kidney can be felt after exposure of the kidney. Simon is even of opinion, judging from the condition of the exposed kidney, as described by Gunn, that in that case the kidney may have contained small stones. The diagnosis of nephrolithiasis can be sometimes fixed by palpation of the kidney through the wall of the belly or from the rectum. In this way one may succeed in feeling a morbid expansion of the pelvis of the kidney, or even a hard resistance in the pelvis of the kidney. If after pains about the kidney, and renal colic, and discharge of matter and blood, gravel is passed with the urine, there will no longer remain any doubt of nephrolithiasis, yet it will often be difficult to decide whether only one or both kidneys are diseased. If often-repeated colic has always occurred on the same side, it is very probable that the kidney of that side only is affected. The probability increases when nothing abnormal is detected by palpation of the other kidney. It becomes a certainty only when the urine once containing pus becomes normal during an attack of colic caused by impaction of the stone and obstruction of the ureter, and when pus reappears with the abatement of the colic.

After exposure of the kidney one can finally have recourse, for the purpose of diagnosis, to acupuncture (Simon). With a needle passed through the substance of the kidney into the pelvis of the kidney, making only a fine and entirely harmless prick, one would be able, it is presumed, should stones exist, to feel them. Only when, after a most careful examination, disease of the other kidney is excluded, should the extirpation of a kidney be undertaken. It will always be advisable, after the exposure of the kidney, to try once more whether one cannot perhaps reach the calculi by incision of the expanded pelvis of the kidney. Simon undertook, on August 8, 1871, the extirpation of a kidney affected with stone. He had previously convinced himself that only one kidney was diseased by observing that the urine during attacks of renal colic was normal. By palpation of the exposed kidney he could not feel any stone. The operation of removal was conducted without much trouble. Eighteen or twenty little stones were found in the extirpated kidney. After a favourable run to the twenty-first day, pyæmia set in, under which the patient (a female) succumbed on the thirty-first day.

Carcinoma and sarcoma, appearing mostly at an early age, are the new formations of the kidney which make an extirpation very desirable. As most of these tumours, however, can be recognized with certainty only after they have attained a considerable size, and as they then project much into the cavity of the belly, they cannot generally be extirpated through a limited incision, but only after opening the peritoneal cavity. One case, however, is known in which the removal was effected by an extra-peritoneal operation. Jessop extirpated (1877) from a child, two years of age, a large encephaloid tumour of the left kidney, projecting in the lumbar region, by means of a lumbar incision. On the fourth day after the operation the child was still going on well. Through a mistaken diagnosis of a hard, round tumour, situated among the muscles of the loins, Langenbuch was induced to perform an extra-peritoneal extirpation of the kidney; for the tumour proved an indurated kidney, striking superficially, situated between the muscles of the loin. The child recovered.

Lastly, fistulæ of the ureter, which cannot be cured in any other manner, also give an indication for extirpation of the kidney. A fistula from which urine flows continually is such a burdensome and tormenting complaint, that the female patients (for only females are troubled with fistulæ of the ureter) would rather undergo a dangerous operation than bear the discomfort any longer. After removal of the kidney the discharge from the fistula ceases as a matter of course. In such cases it is to be expected that the kidney is normal. This circumstance increases the danger of the operation, in so far as that an organ which has worked and performed its functions well up to the end is suddenly removed. Yet, on the other hand, the removal of a healthy kidney can be more easily performed, and performed too without injury to neighbouring tissues, than the extirpation of a diseased kidney. Simon, in 1869, extirpated a kidney on account of an otherwise incurable fistula of the ureter. The lady patient recovered. A patient, operated upon on January 8, 1879, for a similar reason, had completely recovered by February 12.

How the Operation is to be Performed.—The incision for exposing the kidney should be made at the outer edge of the sacrospinalis muscle—that is, about seven centimetres outwards from the line cutting the tips of the spinous processes, and parallel with it—extending from the lower edge of the eleventh rib as far as the middle of the space between the twelfth rib and the crest of the ilium. Then the incision is to be deepened between the lower edge of the twelfth rib and the lower angle of the wound by cutting at first through the latissimus dorsi, and thereby exposing the posterior layer of the lumbar fascia. On dividing this layer of fascia the lateral edge of the sacrospinalis muscle will appear, and is drawn inwards by means of a blunt hook, facilitating this displacement of the muscle, if need be, by the use of the knife. After drawing inwards the muscles, the layer of fascia forming the anterior part of the sheath of the erector spinæ is exposed, and has to be divided in the whole extent of the wound. Thereupon the quadratus lumborum lies before the surgeon. Between this fascia and the quadratus muscle the last intercostal and first lumbar arteries run, and have to be divided and ligatured. If also the quadratus lumborum is cut through as well as the fascia covering its front surface, one comes upon the fatty capsule of the kidney. Between the quadratus lumborum and its fascia, the last dorsal and first lumbar nerves come into view and cannot be spared. Klineberger advises that the incision for exposing the kidney should be curved, with its convexity upwards and inwards, beginning a little below and behind the free end of the twelfth rib, and ending at the outer edge of the sacrospinalis in the middle of the space between the twelfth rib and the crest of the ilium. By this arrangement he thinks it possible to spare the last dorsal and frequently also the first lumbar nerves.

If it is intended only to incise the kidney after exposing it—that is, should the kidney be enlarged owing to expansion of its pelvis—it is easy to feel through the incision, and the kidney cannot possibly be missed. After the fatty envelope is cut through, the kidney lies exposed, and should be incised at a point where the wall of the pelvis is very thin. Only a small incision should be made at first, and afterwards it should be dilated, if possible, with blunt instruments. If an abscess of the kidney has to be opened, one must proceed in a similar manner. If calculi are found in the opened pelvis of the kidney, they should be extracted by the fingers or forceps. If the calculi are too large or too knotty to be extracted thus, they must be crushed in the opened kidney by means of a lithotrite. Callender proceeded in this way in a case which, it is true, finally ended in death. In most cases it will be advisable to keep the incised wound into the kidney open for some time by means of an India-rubber drainage-tube.

If exposure of the kidney has been undertaken for the purpose of its extirpation, a palpable swelling does not exist, as a rule, which would guide the way to the kidney. The latter can therefore be missed if one deviates from the direction which leads straight to the kidney. It is therefore of importance to remember that one is sure to come down upon the kidney at the place where the lower edge of the twelfth rib crosses the lateral edge of the musculus sacrospinalis. In all deeper dissection one must therefore proceed from the point indicated. In most cases the kidney can be distinctly felt after cutting through the quadratus lumborum. After laying open the fatty layer surrounding the kidney, attention must be given to the difficult task of loosening the kidney from its fatty envelope. This has to be done very carefully with the finger. At first an attempt should be made to isolate with one or two fingers the lower part of the kidney, which is *in sitû* at the wound; having succeeded in that, the kidney should be pulled upon at its lower end by the first three fingers, and the upper part should be drawn out from under the ribs, whilst the fingers, which by degrees carefully free the kidney, are gradually pushed forwards.

The fatty envelope cleaves the firmest to the ends of the kidney, and one must therefore be particularly careful when dealing with them; perhaps even it will be well to have recourse to the knife or scissors. If the kidney has been loosened from its surroundings, and its upper part pulled out from under the arch of the ribs, it can be raised so far from out the depth of the wound that one can easily reach its hilus and there ligature the vessels of the kidney. This is best done by several ligatures placed round the pedicle of the kidney after the fatty envelope has been stripped off either with the fingers or forceps. It is better also to tie the pedicle in two portions by passing a curved aneurism-needle armed with a double thread through the middle of the pedicle, taking care to avoid the vessels, and tying each part separately. The employment of two ligatures has, besides, the advantage that, if one of them slips, the parts can be drawn up to some extent by the other.

After ligaturing the pedicle the kidney is cut away, leaving, however, enough of the pelvis of the kidney to prevent the ligature slipping. The operation is then completed. In the depth of the wound the peritoneum can now be seen to heave up and down with each movement of respiration.

If special difficulties should arise whilst loosening the upper part of the kidney, and in pulling it from under the arch of the ribs, either on account of adhesions or of the high position of the kidney, it will be advisable to make the upper part of the kidney more accessible by resecting a piece of the twelfth rib about four centimetres in length. This has, however, to be performed with great care, in order to avoid causing an injury to the pleural sac, which reaches down as far as the upper edge of the twelfth rib. In any case, all the soft parts have to be separated quite close to the rib. The pulling down of the kidney can be facilitated by laying hold of it with a strong pair of forceps. If one considers it practicable, after exposing the kidney, to proceed at first to ligature its vessels, one must pass the fingers on, after incising the fatty envelope, over the median edge of the kidney to the hilus, and isolate and surround with a thread the bundle of vessels which can be easily felt as a compact cord. This proceeding has its particular difficulties, owing to the inaccessibility of the pedicle. If the ligature be tightly tied, it will be best to cut off the vessels with a pair of scissors, leaving a part of the pelvis of the kidney attached to them. Afterwards the extraction of the kidney is undertaken and completed by cutting away the ureter. In those cases in which the extirpation of the kidney is indicated, and the kidney is firmly adherent to its surroundings, Simon proposes to peel out the kidney from its fibrous capsule, and to ligature the vessels within the capsule at the hilus.

The antiseptic precautions applied during the operation, as well as in the after-treatment, will have great importance as regards the result or extirpation of the kidney. Even injuries to the peritoneum during the extraction of the kidney will, it is presumed, not essentially increase the danger of the operation under this treatment. During the first four or five days after the operation, anything pressing upon or interfering with the wound which might produce bleeding must be prevented as far as possible. The bowels therefore must be thoroughly emptied before the operation; opium and a low diet prescribed in the first days afterwards. The catheter must be used if necessary.

The extra-peritoneal extirpation of the kidney had, up to the time of writing, been undertaken eight times. In two cases the patients recovered (Simon, Langenbuch); four cases ended fatally (Simon, Bruns, Peters, Durham); of one case (Jessop's) the issue remained unknown; in the case of Zweifel the condition of the patient after a lapse of four weeks was very favourable. The two operations of Simon lasted about forty minutes each, that of Bruns almost two hours. The extraction of the kidney from its fatty capsule was always the part of the operation which was not only the most difficult, but which also required the most time. In the case of Bruns, the removal was not entirely completed in spite of the resection of a piece of the twelfth rib. In the extraction of a calculous kidney, undertaken by Simon, the fibrous capsule of the kidney tore a little. Zweifel found the kidney inseparably connected with the fatty capsule, and had therefore to peel it out (unhusk it) from its fibrous capsule; the kidney itself was so soft and crumpled that Simon could only with difficulty recognize it as such. Simon did not succeed in his first case in tying the pedicle in two parts, because the veins could not be distinctly recognized on account of the traction on the pedicle, and an injury of the veins had to be feared. In spite of ligaturing the pedicle, bleeding occurred in both of Simon's cases after cutting away the kidney, and could not be checked after the pedicle had been again ligatured.

In the case just mentioned, persistent vomiting for a time continued after the operation, which, however, could not be referred to the disturbances to the secretion of urine, but only to the influence of the chloroform. The normal quantity of urine in Simon's female patient, from whom a healthy kidney was extirpated on account of fistula of the ureter, was discharged on and after the fourth day.—*Med. Times and Gazette*, Oct. 16 and 23, 1880.

A Case of Aneurism of the External Carotid, in which, after failure of the Ligature of the Common Carotid, the Old Operation was performed successfully.

Mr. Henry Morris, at a recent meeting of the Royal Medical and Chirurgical Society (*British Med. Journal*, Oct. 30, 1878), reported the following interesting case:—

Elizabeth P., aged 45, first came under Mr. Morris's care on May 20, 1879, with an aneurism about the size of a walnut at the level of the hyoid bone, and just above the bifurcation of the right common carotid artery. It had been noticed eight months, and it was growing. It was not the result of any injury. She complained bitterly of the pain it caused all over the right side of the head and neck, and of a distressing feeling of dryness about the throat and fauces. She could swallow nothing solid without great suffering; her voice was hoarse, and she spoke in rough whispering tones. Her sight and taste were unaffected. Digital and instrumental compression could not be borne. Diet and medicinal treatment were resorted to, but, her symptoms becoming rapidly worse, on July 16, a catgut ligature was placed around the common carotid artery, on a level with the omohyoid muscle where it crosses the cervical sheath. Four hours and a half afterwards, faint pulsation returned in the aneurism, and continued more or less marked till August 12; when the outline of the aneurism was quite lost, though some pulsation could still be felt along the line of the artery in the situation of, and for a little distance below, the seat of the aneurism. A sinus remained leading down to the point of the ligature, hard, and surmounted with exuberant granulations, from which blood occasionally was discharged. At the end of September, fresh swelling took place at the angle of the jaw; there was no pulsation in it, but, with this exception, all the old symptoms returned. On October 30, there was evidence of suppuration; an incision was, therefore, made, and a small quantity of pus was evacuated from the surrounding tissues. Relief was again obtained, but only partially and temporarily. Though the sinus over the ligature now closed, a similar one, from which blood occasionally escaped in small quantity, remained in the centre of the late incision.

At the end of November, pulsation again was felt; and the swelling, which had much subsided after the escape of the pus, again increased. In fact, the aneurism had now evidently ruptured, was inflamed and growing largely, and threatened to set up ulceration of the tense and distended skin. It was, therefore, treated in the following manner. The facial and superior thyroid arteries were first ligatured, and then the sac was laid open, and all clots turned out. It was now seen that all the bleeding was issuing from the distal end of the sac, and could be checked by passing a tenaculum underneath it and raising it. The incision was prolonged upwards sufficiently far to enable a silk ligature to be passed around the vessel beyond the sac; and, in doing so, a small artery (probably the occipital) and vein were cut, from which bleeding, easily controllable, occurred for the moment. It was specially noticed that no blood had been passing into the sac from the internal carotid, yet that no clot was prolonged into it from the common carotid. The wound did well; the ligature separated on the seventeenth day; convalescence was retarded by an attack of quinsy, which, in the right tonsil, ran on to suppuration; but the patient had quite recovered by February 12, 1880, and still remained well.

Mr. Morris said that the return of the pulsation in the aneurism a few hours after the application of the ligature, the slow consolidation of the aneurism, the pulsation in the vessel on the proximal side of the sac, though not immediately above the ligature, the subsequent growth of the aneurism in spite of the complete obliteration of the common carotid, the violence of the hemorrhage from the distal orifice of the sac at the time of the last operation, together with the absence of any bleeding from the internal carotid, proved how important a part the free anastomoses between the branches of the external carotids of the two sides of the neck, and between the branches of the external carotid and subclavian of the affected side, played in aneurism near the bifurcation of the common carotid. It was suggested, and well-known cases and dissections were quoted to support the suggestion, that, after ligature of the common carotid, no blood usually continued to reach the lower end of the internal carotid in the neck; and that, therefore, the anastomosing circulation within the skull was not the cause of the return of pulsation in these aneurisms, and, therefore, not a cause of the failure of the ligature. The practical conclusion arrived at was that, if the Hunterian ligature were employed in these cases, it were best to supplement it by the simultaneous ligation of such branches of the external carotid as were easily accessible, viz., the temporal, facial, and superior thyroid.

Dr. HILTON FAGGE said that he had met with a case which seemed to confirm Mr. Morris's opinion. A man was admitted into Guy's Hospital with aneurism, and was also hemiplegic. The common carotid artery was tied, and the hemiplegia soon afterwards disappeared. He died some time afterwards; and Dr. Fagge found, on *post-mortem* examination, an aneurism of the common carotid about as large as a pigeon's egg, and containing coagula; it pressed upwards on the internal carotid. There had been evidently interference with the flow of blood upwards to the brain; and, after the operation, the cerebral circulation had been restored by the collateral circulation through the external carotid.

Mr. HARRISON CRIPPS asked why, if the diagnosis, before operation, of aneurism in the external carotid artery were correct, the common carotid had been tied as low down as the omo-hyoid muscle. There was a great mortality after ligature of the common carotid, caused principally by the interference with the circulation in the brain. He thought that a ligature might have been applied to the external carotid, between the aneurism and the common carotid. If the internal carotid were patent in Mr. Morris's case, he did not see why blood did not flow down from it. Considering that there was a violent flow of blood from the distal end of the artery after opening the sac, he thought that the preliminary ligation of the collateral branches was useless. If the object were to cut off the supply of blood through the peripheral branches, he thought that it would be more effectual to tie the carotid of the other side.

Mr. HOLMES said that the case reminded him of one in St. George's Hospital, of ligature of the external iliac for supposed aneurism of the common femoral artery. The aneurism ran exactly the same course as in Mr. Morris's case; and it was so much like a malignant tumour, that the diagnosis was difficult. Local pressure was applied successfully; and the patient died some time afterwards of some other disease. The preparation, which was preserved in the museum of St. George's Hospital, showed the establishment of the collateral circulation. Local pressure would, of course, have been impossible in Mr. Morris's case. Mr. Cripps's question as to the situation of ligature was answered by the fact that the aneurism was close to the bifurcation of the artery. He agreed with Mr. Morris that additional security was gained by tying the main collateral arteries. The diagnosis between aneurism of the external and of the internal carotid arteries was difficult. The regurgitant circulation through the internal carotid was not always so powerful as some supposed.

Mr. CHRISTOPHER HEATH said the suggestion of tying the peripheral branches was admirable, if it could be carried out; but, if only one branch were left, there might be a return current of blood. He thought that it was very difficult to tie all the branches of the external carotid artery. After ligature of the artery on the proximal side, galvanism or the injection of the perchloride of iron into the sac might be tried, before the collateral circulation had been re-established. He did not see the use of tying the carotid on the other side.

Mr. HULKE believed that the injection of perchloride of iron was not safe, unless pressure could be applied on both sides of the sac. He had some years ago made a number of experiments by injecting the perchloride into the veins of dogs, and had found that if pressure were not applied, two drops caused death.

Mr. **Morris** said that, although it might not be possible to tie every branch of the external carotid, yet the diminution of the supply of blood by the ligation of some of them put the patient in a better position. With regard to the use of perchloride of iron, there was a coagulum in the sac in his case, but it was interfered with by the whirl of the returning blood; and the object was to prevent this interference. The recurrent pulsation soon after ligature could be explained by the flow of blood through the branches of the external carotid. Although the results of ligature of the external carotid artery were very favourable, it was impossible to perform that operation in his case.

On Colles's Fracture.

We have noticed, in the number of the *Dublin Journal* for June, 1880, a somewhat interesting paper read before the Ulster Medical Society on February 8, 1880, on the above subject, by Dr. **Henry O'Neill**, assistant surgeon to the Belfast Royal Hospital. Dr. O'Neill is a warm partisan of Dr. Gordon's method of treatment in this injury, and he also shares the views which are prevalent among Irish surgeons as to the absence of impaction in Colles's fracture. It is in relation to the latter point that a strange discrepancy occurs between our Irish *confrères* and the surgeons of Great Britain and the continent; for, while English, Scotch, French, and other surgeons generally believe that fracture of the lower end of the radius is very commonly impacted, the surgeons of Ireland seem to make it almost a personal matter to prove that this is not the case. Dr. R. W. Smith, in his valuable work published in 1850, strongly combats the notion of impaction, and in this he is supported by Dr. Gordon; and Dr. O'Neill adopts the same view, chiefly, however, from *à priori* considerations of the mode of production of the fracture, and from the condition of parts in fractures produced on the dead subject. The fracture, says Dr. O'Neill, "is usually caused by falling on the palm of the hand, with the wrist violently extended; the anterior common ligaments and flexor tendons, being forcibly stretched, act on the anterior border of the carpal surface of the radius at right angles to its long axis, forcing it backwards, so that the radius breaks almost transversely, or with a variable degree of obliquity from before backwards and upwards."

With reference to this, we would say that this, like most of the mechanical explanations of the mode of production of fractures, is, to our minds at least, extremely dubious—and that the fracture seems more probably to be in most cases produced by the transference of direct force from the palm of the hand to the lower end of the radius, a mode of production very likely to cause impaction; while, if the end of the bone is, as Dr. O'Neill imagines, torn away from the shaft by the tension of the ligaments and tendons, impaction would doubtless be less probable, though even then by no means impossible.

With regard to the non-occurrence of impaction in fractures produced on the dead subject, we cannot attribute very much importance to this; since the conditions are so different. But what has always surprised us is that the Irish writers on this subject should persist in ignoring Mr. Callender's evidence, which is positive as to the existence of impaction in three recent specimens dissected at St. Bartholomew's Hospital, as well as other recent specimens preserved in the Museums of the London and Middlesex Hospitals; and this is the more remarkable since Professor Smith, writing in 1850, asks for the very evidence which Mr. Callender produced in 1865 (*St. Bartholomew's Hospital Reports*, vol. i. p. 283.)

Here are Smith's words, quoted by Dr. O'Neill in this very paper. "Until the result of the examination of recent specimens can be adduced in support of the theory of impaction, I shall be inclined to believe that the impaction is only apparent, and that the compact tissue of the shaft is not found enveloped in bone. from its having penetrated the lower fragment at the time of the occurrence of the injury, but because it becomes subsequently encased in osseous matter during the process by which the bony union of the fracture is accomplished."

In reply to this challenge, Mr. Callender produces the notes (and in two cases refers to the preparations) of these instances in which this fracture was dissected in the bodies of persons who had died of other injuries a few hours after the accident, and found to be impacted. Yet the evidence seems not to be satisfactory; at least it is quietly ignored.

Dr. O'Neill does, indeed, admit that when the lower end of the radius is broken by a fall on the back of the wrist, impaction does occur. But any reader of Mr. Callender's paper can see that that careful and accurate writer had distinguished between this less common form of Colles's fracture and the ordinary cases, to which latter class all three above-mentioned belonged. Mr. Callender shows that the direction of the impaction is found to vary with the direction of the force, as it naturally would; we cannot therefore avoid subscribing to the belief of those who admit the frequent occurrence of impaction in this injury. The question is one of considerable importance in the treatment. For, to those who believe in impaction, the point of chief moment is that such impaction should be if possible disengaged, and the parts put in a perfectly natural position, at the time of the injury. This is usually not difficult. "The deepest impaction," says Mr. Callender (meaning the deepest he has met with among the specimens in various museums), "does not exceed five-tenths of an inch, usually it is much less," so that firm traction under anæsthesia would properly disengage the fragments in any case where they could not otherwise be brought into apposition; and we believe that, when the parts are thoroughly reduced at first, the injury may be very successfully treated by straight back and front splints. We say this with no hostility to Gordon's splint; in fact, we believe with him that the great essential of successful treatment is to restore the proper concavity of the front surface of the lower portion of the radius; and, so far as Gordon's splint insures this end, it is of value. But accurate reduction necessarily involves the restoration of the natural shape of the bone—and it is difficult to see what there is to displace the lower end again when once it has been reduced and is kept quiet. We repeat that personally we have a high opinion of Dr. Gordon's splint, and have used it successfully; but we feel that a too exclusive trust in this or any other form of apparatus has some tendency to lead the surgeon astray from what ought to be his first and great object—the accurate reduction of the parts at the earliest possible moment, and by the exertion of any necessary amount of force which seems justifiable.—*Lond. Med. Record*, Oct. 15, 1880.

—

Cross-Legged Progression (Scissor-Legged Deformities) the Result of Double Hip-Anchylosis.

Mr. Clement Lucas, at a recent meeting of the Clinical Society of London (*Med. Times and Gazette*, Oct. 30, 1880), read a paper on cross-legged progression (scissor-legged deformities) the result of double hip-anchylosis. The object of the paper was to direct attention to a peculiar and characteristic gait brought about by anchylosis of both hip-joints, and hitherto undescribed. Two patients were exhibited to illustrate the cross-legged mode of walking, one a boy aged ten, and the other a man aged forty-seven. In each case the disease had existed for some time in one hip-joint before the other had become affected. Gradually, as the patient walked with the aid of sticks or crutches, the limb last attacked was carried across the other, and becoming anchylosed in this position, compelled the patient to walk permanently cross-legged. The legs placed in this position suggest in their crossing the appearance of a pair of scissors. The author left it open to discussion how this position was acquired—whether as the simple result of the adduction which is so common a sequence of hip disease, or as the gradually developed, perhaps unconscious, action on the part of the patient to place his limbs in the position most favourable for progression. Mr. Lucas gave the following explanation as the most practicable. The patient, when commencing to walk on the convalescent limb, finds that by resting the other limb upon it he can steady the inflamed hip, and prevent the movements which cause him pain. At the same time, by the oblique position the limb is shortened and rendered less liable to touch the ground. As recovery goes on in the hip last attacked, the patient from time to time tests its condition by dropping the supported foot to the ground and leaning a little weight upon it. Gradually he takes more and more weight from the crutches, still retaining the limb in the oblique position, and finally, the second hip having become anchylosed, he is able to throw aside his crutches and walk in the peculiar manner illustrated by these two patients.

The author showed that in ordinary walking the forward movement takes place entirely from the hip, the knee-movement being of service only to shorten the limb and prevent the feet touching the ground when in the act of being advanced. Hence, should both hips become fixed when the limbs are parallel, progression could only take place by twisting first one side of the body, then the other, to the front. The patient finds out for himself that by carrying one limb across the other, so as to render the knees oblique, the knee-movement can be made to take the place of hip-movement, and knee-walking is thus substituted for hip-walking. In both the patients exhibited, the right leg (that last attacked) was in advance of the other.

The first patient, a boy aged ten, began to suffer from disease of the left hip when four and a half years of age, and attended as an out-patient at the Evelina Hospital under Mr. Lucas's care. Fifteen months later, after a fall, the right hip became diseased. He continued under Mr. Lucas's care till June, 1877, when he was admitted into the hospital under the care of Mr. Morrant Baker. After resting in the hospital three months he was discharged, and again attended as an out-patient. For twelve months after his discharge he was kept lying during the greater part of the time; he was then allowed to walk with crutches, the left hip being, however, anchylosed. He was then sent into the country, and on his return it was found that he had learnt to walk with both legs, and that they were fixed in the scissor-like position.

The second patient exhibited, Mr. Lucas saw walking in the street, and diagnosed his condition by the light of the other case. A man, aged forty-seven, first began to suffer pain in the left hip in the year 1870. He was at this time employed as a coal-heaver. He sought advice at St. Thomas's Hospital, and afterwards at St. Bartholomew's. Subsequently he spent thirteen months in the Dalston Infirmary. After this, for a year, he tried to work a little, but remained lame. Since that time he has gained his living by hawking trifles in the streets. In September, 1879, he began to suffer pain in his right hip. Up to this time it had been his custom to rest most of his weight on his limb, but the pain now caused him to stand chiefly on the left leg. In the course of the winter he got into the habit of crossing his legs, but at first was able to unlock them at will. Later he used to unlock them at night-time, when he retired to sleep; but gradually this became more difficult, and they are now firmly fixed in the cross-legged position.

Mr. J. Croft said that among the cases of excision of the hip which came under his care last year he had had one which was double. This ended in recovery; but the mode of walking was different from that here presented; the conditions also were different. The patient walked with one knee in front of the other, and there was some lordosis. Much improvement was effected by cutting through the femur on one side and breaking through the adhesions on the other. All cases of double hip-joint disease, however, did not end like these. In the child exhibited there had probably been a double dislocation; and so likewise in the man. He thought the best plan of affording relief would be to cut through both femurs below the great trochanter.

Mr. HOWARD MARSH said that such cases may and ought to be cured without displacement. The cause of the peculiar gait in the man was that his limbs had been allowed to go wrong. And the tendency to displacement should have been obviated by splints and weights. The man did not walk in that peculiar fashion because he had had hip disease, but on account of the position the limbs had been allowed to take. He would cut the femurs.

Mr. LUCAS, in reply, said that the scissor-like position was assumed so that the knee-joint might be used after the manner of the hip-joint. In reply to Mr. Heath, he said he did not think there was dislocation in the man.

Medical Jurisprudence and Toxicology.

An Epidemic of Ergotism.

This epidemic, described by SWIATLOWSKY (*St. Petersburg. Medic. Wochenschr.*, 19th July, 1880) occurred during the autumn of 1879 in the neighbourhood of Novgorod. In the district attacked, an inhospitable climate and a marshy soil were combined with poverty, dirt, and generally unhealthy conditions among the villagers. Of nineteen cases in which the symptoms were strongly marked, four died. In other sixteen cases the symptoms were less developed, and probably as many more escaped observation. In these slighter cases the symptoms were diarrhœa (in seventy per cent.), weakness, more especially in the hands and feet, occasional attacks of giddiness, headache, sleeplessness, and deadness of the fingers, with formication under the skin. All had, up to their seizure, eaten fresh-ground unkilned rye, and the symptoms quickly disappeared under the use of laxatives and opiates, and the withdrawal of bread containing ergot. In the first-mentioned nineteen cases the symptoms were severer: racking pains in the extremities, severe headache, great thirst and utter prostration, with weakness of intellect and melancholia. Tonic and clonic spasms preceded by dyspnœa, deadness in the extremities, and cold sweats, attacked the flexor muscles of the limbs, the extensors being unaffected. In no case did gangrene occur. The respirations were 14.16; maximum temperature 99.8 deg., minimum (in three cases) 95.9 deg.; pulse slow and weak. The fatal cases, an old man and two children in one family and a woman in another, died, three of them in a comatose condition and one during a convulsive fit. The treatment was as above, with subcutaneous injections of morphia, and inhalations of chloroform, followed by tonics and improvement of hygienic conditions. The quantity of ergot present in the rye was about seven per cent., and two dogs fed with it each showed on the seventh week a gangrenous ulcer on one paw. On withdrawal of the ergot-bread from one dog, recovery followed in two months; while in the other, fed as before, the gangrene advanced, convulsions appeared, and death followed by way of coma in the tenth week. The *post-mortem* appearances were: brain and meninges anæmic, arteries quite empty, veins full of dark fluid blood, heart empty, lungs, liver and spleen hyperæmic, intestinal mucous membrane congested, but neither it nor the liver showing any gangrenous spots such as have been described.—*London Med. Record*, Oct. 15, 1880.

MEDICAL NEWS.

Privileged Communications.

A movement is on foot, and has received the sanction of a very large majority of the medical profession in Pennsylvania, to procure from the State Legislature the passage of a law extending privilege to communications between physicians and their patients. Such a law, wisely framed, is for the advantage of the whole public as well as of the special class concerned in it, and that it is eminently desirable that it should be placed upon the statute-book, may be readily perceived by any one who will look into the matter.

From the peculiar circumstances under which physicians are apt to be admitted to the private lives of their patients, many things must accidentally fall under the notice of the former, and others are often imparted to them, not in their professional capacity, which they justly regard as a point of honour to keep under the seal of confidence. This principle was distinctly recognized in the time of Hippocrates, and in the Code of Ethics of our own day it is clearly set forth. While, however, matters of this kind are not to be even spoken of under ordinary circumstances, they do not come within the compass of the law now sought.

The idea of this movement is to protect the physician or surgeon and his patient in such communications as their mutual relations may demand; that whatever it is needful for the former to know in order to the intelligent treatment of a case, the latter may reveal without fear of its subsequent exposure. It is of the utmost importance that the patient should be free to place such confidence in his medical adviser, and to put him in possession of all the information needed for the due discharge of his functions; and that the physician on his part should be equally free in inquiring into all points bearing upon the proper understanding and management of the case. For want of such facts, the treatment instituted may be either inefficient or wholly erroneous.

Custom, if not law, has everywhere recognized the secrecy of the confessional, and lawyers can plead privilege against any attempt to elicit from them the statements made to them by their clients. Obviously, the same reasoning which has led to this exemption of the clerical and legal professions, applies with equal force in the case of the medical. There is an old maxim to the effect that a man should have no secrets from his priest, his lawyer, or his doctor.

It should be understood that if the physician goes outside of his province, he at once goes outside also of the protection which the proposed law would give him. He becomes then, in regard to all other matters, an ordinary witness, and as such may be called upon to give up the facts in his possession to the proper authorities.

That the proposed law for Pennsylvania will work greatly to the advantage of the profession and relieve us from many serious annoyances and embarrassments we can readily understand. That it will not injure the public we also believe, upon one condition, viz., that one word be stricken out.

The draft of the law reads as follows: "No person duly authorized to practise physic or surgery shall be allowed or compelled to disclose any information which he may have acquired in attending any patient in his professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon," and the word we object to is "allowed." To say that a medical man who becomes cognizant of murder, abortion, or other crime, shall not be "compelled" to disclose such a confidential communication is very well. But if the circumstances surrounding the case seem to him as a good citizen to compel him, as a matter of conscience and duty, to bring such wrong to the attention of the proper prosecuting officer, who forsooth has the right to say he shall not be "allowed" to do so? Least of all has the public who suffer from such crimes. Especially is this true of abortion, which even with existing laws is so rife. Gladly will the doctor aid in protecting any poor deceived girl who may be rescued from a life of future infamy by his refusing to be "compelled" to disclose the facts; but if he see that her life is sacrificed and that through his silence the wrong-doer and the abortionist are to escape the punishment which the good of society demands, it is not only a violation of his personal liberty of conscience and his rights as a good citizen to shut tight the only mouth, it may be, that can convict the criminals, but all of our sense of right revolts at such an enforced silence.

Many reasons make such a prohibition proper for the lawyer. But while it is contended that "legal custom has forbidden any interference between a penitent and his priest," the *law* is, that the priest, if it be insisted on, must disclose the facts or suffer the consequences. Hence, if the law protects medical men from being "compelled" to testify, it will protect us even more than it does the clergy, and with this we may well be satisfied without enforcing silence on unwilling consciences to the detriment of the community.

The satisfactory working, for a greater or less period, of similar laws in Arkansas, California, Indiana, Michigan, Iowa, Missouri, Minnesota, New York, and Wisconsin, may be appealed to as practical proof that the action now asked for at the hands of the Legislature of Pennsylvania would be in furtherance of the public interest. Especial stress is needed on this point, since the fact that the matter has been agitated by the medical profession might at first sight give the idea that the enactment was desired by them only and for their sole benefit.

We trust that this effort to obtain salutary protection for the medical men of this commonwealth and their patients may be favourably met by the law-makers, and should be glad if the mention of it in these pages should induce similar action in other States.

LITERARY PIRACY.

Most of our readers are familiar probably with the "American Health Primers," published within the past eighteen months by Mr. Presley Blakiston, of Philadelphia. We should be glad to learn that they had been so esteemed as to lead to their republication in England, were it not for the fact that in doing so the English publishers, Messrs. Ward & Lock, have seen fit to commit an act of the grossest injustice. They have announced thus far six of the series, of which we have seen but four, and can therefore only speak of these. The chief wrong they have done is to omit entirely the names of both editor and authors, and announce the series as "written and edited by distinguished members of the medical profession," thus misleading the British public into the belief that the books are of European and not American origin. And to carry out still further this deception, they call them "Ward & Lock's Long Life Series," as though it were an independent and original publication. And, still further, in cases where the text would discover the American origin of the book, whether by direct statement or by allusion to cis-Atlantic customs, statistics, men, and manners, they have indeed "carefully edited" them by changes and omissions. In Dr. Harlan's and Dr. White's Primers only one sentence in each needed alteration, in Dr. Cohen's perhaps a dozen, while in Dr. Richardson's a couple of score of changes are made—not to add to the value of the books but to conceal their American origin.

We wish we could say that the republication of the "American Health Primers" redounded as much to the honour as it does to the literary discernment of the English publishers. As it is it is piracy in its worst form, and swift condemnation should follow its exposure.

Gift of Harvey Memorials.

At the November meeting of the College of Physicians of Philadelphia, Dr. Weir Mitchell presented to the College some very interesting Harvey memorials which he collected during his recent visit to England and to the grave of Harvey, in the village church at Hempstead about seven miles from Saffron Walden in the county of Essex. In his visit to Hempstead Dr. Mitchell was accompanied by Dr. Benj. W. Richardson, of London, who has been principally instrumental in recalling to public notice the tomb of the great anatomist.

Dr. Richardson in early life (1847) was assistant to the surgeon at Saffron Walden, and while attending a neighbouring cottager's wife in her accouchement her husband entertained him with an interesting story of the chapel and vault of the "great Dr. Harvey." It gradually dawned upon Dr. Richardson that the Harvey referred to must be the discoverer of the circulation of blood, and on further inquiry this proved to be the fact. Up to that time the Harvey vault had not been visited by men of science within the memory of any of the surrounding inhabitants, and it had been long neglected and had fallen sadly out of repair. The villagers knew that Dr. Harvey was a celebrated man, who belonged to a distinguished county family, and had made some great discovery, but they did not know what it was. Dr. Richardson subsequently visited the vault and through his influence it was repaired and public attention called to the resting-place of the remains of the great Harvey.

In 1878, Dr. Richardson, with a photographer, made a visit to Harvey's tomb at Hempstead, and took a series of six photographs, copies of which Dr. Mitchell procured, had framed, and with fac-simile tracings of the inscription on the monument and on the sarcophagus of Harvey presented to the College. Two of these photographs represent different views of the exterior of the church, which dates back to the reign of Henry the Seventh, and one of its interior with the Harvey chapel, a handsome little annex over the Harvey family vault in the northeast corner of the church. Two others represent the front and profile view of the marble tablets or monument containing the bust of Harvey which is erected in the church. The ornamentation of the tablet is bold and effective, and below the bust is a lengthy and appropriate Latin inscription, a fac-simile copy of which Dr. Mitchell obtained by rubbing on tracing paper. A careful study of this bust which Dr. Richardson made in connection with Mr. Woolner, a sculptor and Royal Academician, led him to the belief that it was copied from a cast made after death, and that it was done with true artistic delineation, but that all that he was obliged to add to make up the bust as it stands, as for instance the ears, hair, drapery, etc., is of the worst possible quality.

The concluding photograph of the series is a view of the vault and of the sarcophagus containing the remains of Harvey which was obtained by the aid of the magnesium light. The leaden case or sarcophagus is represented as roughly shaped in the form of the body. The head has the rude outline of a face with mouth, nose, and eyes; the body is long and tapering towards the feet. The breast plate is broad and the inscription on it is in raised letters: "Docter William Harvey decesed the 3 of Ivne 1657, aged 79 years," a fac-simile copy of which Dr. Mitchell obtained by rubbing.

In accepting the gift of these interesting Harvey memorials the College voted its thanks to Dr. Mitchell.

Pulverization of the Bromides in Pertussis.—The good effects of bromide of potassium are well known, and, according to Dr. Wintrebert, the way to render this medicine still more useful is to bring it in direct contact with the respiratory passages by pulverization. He habitually employs the solution of 20 per cent. after each paroxysm, this having cleared away the mucosities so as to enable the remedy to gain direct access to the mucous membrane.—*Med. Times and Gaz.*, Oct. 30, 1880, from *Presse Belge*, Oct. 17.

The German Pharmacopœia.—The Imperial Government of Germany has appointed a commission, which has already commenced its sittings at Berlin, for the revision of the German Pharmacopœia. The commission consists of twenty-seven members, of whom sixteen are professors from various universities, five are apothecaries, and the remaining six are eminent practising physicians or surgeons. The Prussian War Office has deputed two military doctors and a military apothecary to attend the sittings. Dr. Schmidt, Professor of Pharmacy at the University of Halle, will act as secretary to the commission, which is presided over by Privy Councillor Dr. Struck, director of the Imperial Sanitary Department.—*Lancet*, Oct. 23, 1880.

Angels in the House.—In the last fasciculus of the *Bulletins de la Société d'Anthropologie de Paris* (tome iii, fasc. 2), M. Bertillon gives the results of his comparative analyses of the statistical tables of suicides for France and Sweden. These results show singular accord between the two countries, and the author considers himself justified in maintaining that they establish the two following laws. 1. Widowers commit suicide more frequently than married men. 2. The existence and presence in the house of children diminishes the inclination to suicide both in men and in women.—*British Med. Journal*, Oct. 30, 1880.

British Medical Association.—The Council have decided that next year's meeting of the Association shall be held at the Isle of Wight, on account of its accessibility to the distinguished foreigners who may attend the International Congress in London in 1881. Mr. Benjamin Barrow, of Ryde, has been appointed President-elect.

The Weir Mitchell Library Fund of the College of Physicians of Philadelphia.—At the November meeting of the College of Physicians, Dr. Alfred Stillé, Chairman of the Library Committee, reported that he had received from Dr. Weir Mitchell a check for one thousand dollars, the income from which was to be applied to subscriptions to current periodicals or to such other use as the Library Committee might direct. The College passed a vote of thanks to Dr. Mitchell for his generous gift, and directed the treasurer to invest the same, and to keep a separate account of it as the "Weir Mitchell Library Fund," and to pay over the income to the Library Committee in accordance with the terms of the gift.

Southwest Virginia Medical Society.—A meeting of physicians of the 9th congressional district of Virginia was held at Marion on the 17th of September to organize the Southwest Virginia Medical Society. Dr. S. C. Gleaves, of Wytheville, was called to the chair. It was resolved to effect a permanent organization, and Dr. W. F. Barr, of Abingdon, was elected President, and John S. Apperson, M.D., of Smyth, Recording Secretary and Treasurer. Meetings are to be held quarterly, and the first stated meeting was held at Marion on the 28th of October, and the permanent organization was completed.

Break-bone Fever in Charleston.—The break-bone fever which prevailed in Charleston during the autumn has disappeared with the advent of cold weather and frost. From the *National Board of Health Bulletin*, Nov. 6, 1880, we learn that break-bone fever at the same time prevailed extensively in Northern Egypt, which corresponds in geographical latitude with the Gulf Coast of the United States, where it also existed. The isothermal difference is about ten degrees.

Physicians in Chicago.—According to the *Register*, just published, under the direction of Dr. D. W. Graham, there are 409 regular physicians in Chicago who are in affiliation with the Code of Ethics of the American Medical Association.

Smallpox in Chicago.—Smallpox is on the decline in Chicago; 177 cases have been treated in the hospital from January 1st to October 1st, of which 30 or 11 per cent. have proved fatal.

Massachusetts Medical Society's Prize.—The Committee on Publications offer the sum of *two hundred dollars* as a prize to any one Fellow of the Society who shall give, on or before the 15th of April next, in an essay or report (worthy of a prize), the best and fullest evidence of any original or meritorious *professional work*, done by himself during the two years next preceding said date—in experimental investigations, scientific researches, or clinical observations.

—

Resignation of Prof. Klebs.—Prof. Klebs has resigned his chair of Pathological Anatomy in the Medical Faculty of the University of Prague. He has done so, we understand, because his request for additional space for pursuing his investigations has been refused by his colleagues in the College of Professors. The students, with whom he is so great a favourite, are endeavouring to induce him to recall his resignation, and the Minister of Public Instruction has called for a report on the subject from the Professors' College. Prof. Klebs is in bad health, and is at present at Carlsbad.—*Med. Times and Gaz.*, Aug. 7, 1880.

—

Literary Notes.—The autumn has not been prolific of literary announcements. H. K. Lewis, of London, has nearly ready, "Elements of Practical Medicine," by Alfred H. Carter, M.D., Physician to the Queen's Hospital, Birmingham; and Williams and Norgate have just published "Lectures on Digestion," by Dr. C. A. Ewald, of the Royal University of Berlin.

Of new journals we have received the first number of the *Specialist*, a monthly quarto of 14 pages, published by Churchill, of London, and devoted, as its name implies, to the specialties. Mr. Presley Blakiston reprints it in consolidation with his *Intelligencer*, under the editorship of Dr. Charles W. Dulles—whose name is favourably known in medical literature.

The *Rocky Mountain Medical Review* is a monthly of forty pages, the first number of which was issued in September, and is edited by A. Wellington Adams, M.D. It hails from Colorado Springs, and its contents, make-up, and mechanical execution, give it an extremely attractive appearance.

An important work on medical jurisprudence, in three volumes, is announced by H. Laup, of Tübingen. It is to be edited by Dr. Maschka, and written by a series of experts, including Drs. Eulenberg, Drogendorff, Oesterlen, Emminghaus, Krafft-Ebing, and other well-known names.

The *British Medical Journal* (Oct. 16), in acknowledging the receipt of the "Subject-Catalogue of the Library of the Surgeon-General's Office," says of it that "it is a perfect marvel of care, accuracy, and completeness. Although Dr. Billings, its accomplished compiler, modestly disclaims for it all pretensions to a complete medical bibliography, yet the known industry with which the agents of the library in London, Paris, Leipzig, Amsterdam, St. Petersburg, and other great book-marts collect books for it, probably makes the catalogue the most complete in the world for medical literature."

—

OBITUARY RECORD.—Died, at Springfield, Ill., on the 27th of October, RUFUS S. LORD, M.D., Surgeon-General of the Illinois National Guard.

The death of Professor BUHL is announced. His studies in pathology, and especially in the pathology of tubercle, have rendered his name well known both at home and abroad.

—

To Readers and Correspondents.—The editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

Shoulder, old dislocation of, rupture bloodvessel in reducing, 114
Siegen, oil of eucalyptus, 595
Sight, relation of, to hygiene of school room, 56
———, short-, and school books, 614
Sinclair, effects of long-continued lactation upon ovaries and uterus, 648
Skin, summer diseases of, 385
Smallpox eruption, local treatment of, 665
——— in Chicago, 763
———, local antiseptic treatment of, 470
Smith, clamp and cautery in hemorrhoids and prolapsus, 392
———, summer complaint of infants, 328
Southam, fat-embolism in fractures, 689
Spinal cord, reflexes in, 28
———, regeneration of, 655
———, secondary degeneration of, 535
——— disease in workers in zinc, 158
Spine, treatment of lateral curvature of, 424
Spleen, enlarged, 449
Sprains, treatment of, 692
Sprengel, incomplete lateral dislocations at elbow, 426
Stadfeldt, antiseptic treatment of uterus after delivery, 504
Stammering, 30
Sterility, acidity as a cause of, 564
———, causation of, 51
——— cured by excision of an anomalous membrane, 694
Stethoscope, modification of binaural, 574
Stewart, ammonium chloride and iron, 82
Stoker, removal of uterus and ovary for relief of subperitoneal uterine tumour, 305
Stomach, diseases of, 97
Strabismus, convergent, intermittent, 547
———, therapeutics of, 676
Straus, erysipelas of lung, 93
Strychnia poisoning, artificial respiration in, 659
Sturges, fatal chorea, 538
———, gangrene of lung, 397
Subastragaloid dislocation, 244
Sulpho-cyanide of potassium, 661
Summer complaint of infants, 328
Sweating, influence of, on gastric juice and urine, 79
Swiatlowsky, epidemic of ergotism, 758
Syphilis and laryngeal phthisis, diagnosis between, 474
———, epileptiform, 90
———, hemorrhagic, 600
———, infantile, treatment of, 600
———, inoculation of, by tattooing, 352
———, malignant, 613
——— of bloodvessels, 674
——— ——— conjunctiva, 676
———, prognosis and treatment of primary, 495
———, traumatic lesions in, 496
Szuman, resection of thorax, 355

Tabes dorsalis, syphilis a cause of, 342
Tænia, remedies for, 701
Tait, axial rotation of ovarian tumour, 306
Talipes, treatment of, 321
Taylor, resection of ribs for empyema, 40

Tayuya, 267
Tea, toxic effects of, 54
Teevan, litholapaxy, 18
Temperature, local, in diseases of abdomen, 95
———, morbid, 149
Tendon reflex, patellar, significance of absent, 159
Tennessee, Medical Society of, 381
Tenotomy of muscles of eye, partial, 743
Test pellets, 253
Tetanus, hydrophobic, 27
——— traumatic, treatment of, 48
Texas State Medical Association, 509
Thermometer in diagnosis, 597
Thermometers, certification of correctness of, 572
Thin, bromidrosis of feet, 675
Thomas, clinical lecture on diseases of women, 193
Thompson, catarrh of the bladder, 263
———, pulmonary syphilis, 673
———, treatment of stricture of urethra, 683
Thomson, colour blindness, 705
Thorax, resection of, 355
Thornton, ovariotomy following incision and long drainage, 118
———, removal of uterine fibroids by laparotomy, 374
Thorowgood, ascites tapped with Southey's trocar, 334
Thrombosis, multiple, 682
Thyroid gland, accessory, 20
———, excision of, 491
Tillaux, hysterotomy for fibroids of uterus, 52
Tongue, appearance of, in disease, 32
Tonsillitis, hemorrhage from carotid artery in phlegmonous, 43
Toys, dangerous, 700
Transfusion, methods of, 98
Tripier, modified amputation of foot, 366
Tuberculosis as a contagious disease, 403
——— an infectious disease, 532
——— in infants, 31
———, iodides of potassium and iron in, 162
———, transmissibility of, by milk, 533
Tulip, physiological action of alkaloid extracted from garden, 722
Tumour, removal of, without leaving scar, 613
Tupper, unusual effect of hypodermic injection of morphia, 25
Turpentine, Chian, in cancer, 295, 737
Typhoid fever and polluted water, 380
———, disinfection of stools in, 470
——— during pregnancy and puerperal state, 505
———, parasites in muscles in, 341
———, specific agent of, 723
———, treatment of, 83, 151

Ulcer of foot, perforating, 108
———, syphilitic, pyrogallic acid in, 496
Umbilicus, fungosities of, 303
Uræmia, pilocarpine in, 163, 541
Urethra, stricture of, progress in treatment of, 683
Urethro-perineal inflammation due to gonorrhœa, 360
Urethrotomy in obstinate strictures, 423
Uric acid, quantitative test for, 287
Urine, incontinence, 495
Uterus, amputation of supravaginal, in fibroma, 623
——— and ovary, extirpation of, 183, 305
———, double, 19
———, with double conception, 49, 180
———, cervix of, condition of, in non-pregnant, 249
———, fibroid of, treated by continuous currents, 304
——— laparotomy, 374
———, Freund's operation for extirpation of cancerous, 118, 304
———, medication through, 700
———, prolapsus of, elytrorrhaphy for, 303
———, prophylactic washing-out of, with carbolic lotion after delivery, 504
———, retroversion of gravid, with rupture of bladder, 437
———, rupture of, etiology and treatment of, 695
———, secondary syphilitic affections of, 621
———, total extirpation of, from vagina, 622
———, versions and flexions of, indications for treatment of, 372

Vaccination, intra-uterine, 117
Vagina, double, 19
———, secondary syphilitic affections of, 621
Vaginismus, 52
Vaginitis, 456
Vagus nerve, removal of, with tumour of neck, 677
Varicocele, modification of Lee's operation for cure of, 553
———, radical cure of, by galvanic écraseur, 521
Vaseline in gynæcological practice, 83
Vaso-motor action, 656
Verneuil, indications for operations in cases of constitutional disease, 36
Version, amputation of procident arm to facilitate, 561
———, spontaneous, 181
Vertigo, auditory, 711
———, gastric, 409
Virginia, Medical College of, 573
——— Society, Southwest, 763
Viscera, transposition of, 571
Vision, disturbances of, by injuries of skull, 291
Vocal cords, cysts of, 492
Voltolini, emphysema after inflation of tympanum, 743
Vomiting of pregnancy, inhalation of oxygen in, 561
Volta prize, 573

Wecker, cure of glaucoma by sclerotomy, 37
Weinlechner, treatment of strictures of the œsophagus, 292
Wells, Mr. Spencer, one thousand cases of ovariotomy, 507
Wharton's duct, singular obstruction of, 614
Whittaker, cirrhosis of liver, 641
Wickersheimer's preservative fluid, 186
Wieger, hyaline degeneration, 285
With, peritonitis appendicularis, 481
Wittelshofer, congenital abnormal development of the extremities, 19
Women, clinical lecture on diseases of, 193

Yellow fever epidemic, treatment of infected localities at end of, 58
——— on the lower Mississippi, 699
———, pathology of, 121
Yeo, coto bark in diarrhœa of phthisis, 34

Zeissl, treatment of gonorrhœa, 297, 357
Zielewicz, hæmophilia, 471

HENRY C. LEA'S SON & CO.'S

(LATE HENRY C. LEA)

CLASSIFIED CATALOGUE

OF

MEDICAL AND SURGICAL PUBLICATIONS.

In asking the attention of the profession to the works advertised in the following pages, the publishers would state that no pains are spared to secure a continuance of the confidence earned for the publications of the house by their careful selection and accuracy and finish of execution.

The large number of inquiries received from the profession for a finer class of bindings than is usually placed on medical books has induced us to put certain of our standard publications in half Russia, and that the growing taste may be encouraged, the prices have been fixed at so small an advance over the cost of sheep, as to place it within the means of all to possess a library that shall have attractions as well for the eye as for the mind of the reading practitioner.

The printed prices are those at which books can generally be supplied by booksellers throughout the United States, who can readily procure for their customers any works not kept in stock. Where access to bookstores is not convenient, books will be sent by mail post-paid on receipt of the price, and as the limit of mailable weight has been removed, no difficulty will be experienced in obtaining through the post-office any work in this catalogue. No risks, however, are assumed either on the money or on the books, and no publications but our own are supplied, so that gentlemen will in most cases find it more convenient to deal with the nearest bookseller.

An Illustrated Catalogue, of 64 octavo pages, handsomely printed, will be forwarded by mail, post-paid, on receipt of ten cents.

HENRY C. LEA'S SON & CO.

Nos. 706 and 708 Sansom St., Philadelphia, December, 1880.

INCREASED INDUCEMENT FOR SUBSCRIBERS TO

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

TWO MEDICAL JOURNALS, containing nearly 2000 LARGE PAGES, Free of Postage, for FIVE DOLLARS Per Annum.

TERMS FOR 1881.

The American Journal of the Medical Sciences, published quarterly (1150 pages per annum), with The Medical News and Abstract, monthly (768 pp. per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The American Journal of the Medical Sciences, when not paid for in advance, Five Dollars.

The Medical News and Abstract, free of postage, in advance, Two Dollars and a half.

⁂ Advance paying subscribers can obtain at the close of the year cloth covers, gilt-lettered, for each volume of the Journal (two annually), and of the News and Abstract (one annually), free by mail, by remitting ten cents for each cover.

It will thus be seen that for the moderate sum of Five Dollars in advance, the subscriber will receive, free of postage, the equivalent of three or four large octavo volumes, stored with the choicest matter, original and selected, that can be furnished by the medical literature of both hemispheres. Thus taken together, the "Journal," and the "News and Abstract" combine the advantages of the elaborate preparation that can be devoted to the Quarterly with the prompt conveyance of intelligence by the Monthly; while the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable when periodicals from different sources are taken together.

The periodicals thus offered at this unprecedented rate are universally known for

(For "The Obstetrical Journal," see p. 24.)

their high professional standing.

I.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES,

EDITED BY I. MINIS HAYS, M.D.,

for more than half a century has maintained its position in the front rank of the medical literature of the world. Cordially supported by the profession of America, it circulates wherever the language is read, and is universally regarded as a national exponent of American medicine—a position to which it is entitled by the distinguished names from every section of the Union which are to be found among its collaborators.* It is issued quarterly, in January, April, July, and October, each number containing about three hundred octavo pages, appropriately illustrated wherever necessary. A large portion of this space is devoted to Original Communications, embracing papers from the most eminent members of the profession throughout the country.

Following this is the REVIEW DEPARTMENT, containing extended reviews by competent writers of prominent new works and topics of the day, together with numerous elaborate Analytical and Bibliographical Notices, giving a fairly complete survey of medical literature.

Then follows the QUARTERLY SUMMARY OF IMPROVEMENTS AND DISCOVERIES IN THE MEDICAL SCIENCES, classified and arranged under different heads, and furnishing a digest of medical progress, abroad and at home.

Thus during the year 1879 the "JOURNAL" contained 67 Original Communications, mostly elaborate in character, 147 Reviews and Bibliographical Notices, and 215 articles in the Quarterly Summaries, illustrated with 70 wood engravings.

That the efforts thus made to maintain the high reputation of the "JOURNAL" are successful, is shown by the position accorded to it in both America and Europe as a leading organ of medical progress:—

This is universally acknowledged as the leading American Journal, and has been conducted by Dr. Hays alone until 1869, when his son was associated with him. We quite agree with the critic, that this journal is second to none in the language, and cheerfully accord to it the first place, for nowhere shall we find more able and more impartial criticism, and nowhere such a repertory of able original articles. Indeed, now that the "British and Foreign Medico-Chirurgical Review" has terminated its career, the American Journal stands without a rival.—*London Med. Times and Gazette*, Nov. 24, 1877.

The best medical journal on the continent.—*Boston Med. and Surg. Journal*, April, 1879.

The present number of the American Journal is an exceedingly good one, and gives every promise of maintaining the well-earned reputation of the review. Our venerable contemporary has our best wishes, and we can only express the hope that it may continue its work with as much vigor and excellence for the next fifty years as it has exhibited in the past.—*London Lancet*, Nov. 24, 1877.

The Philadelphia Medical and Physical Journal issued its first number in 1820, and, after a brilliant career, was succeeded in 1827 by the American Journal of the Medical Sciences, a periodical of world-wide reputation; the ablest and one of the oldest periodicals in the world—a journal which has an unsullied record.—*Gross's History of American Med. Literature*, 1876.

The best medical journal ever published in Europe or America.—*Va. Med. Monthly*, May, 1879.

It is universally acknowledged to be the leading American medical journal, and, in our opinion, is second to none in the language.—*Boston Med. and Surg. Journal*, Oct. 1877.

This is the medical journal of our country to which the American physician abroad will point with the greatest satisfaction, as reflecting the state of medical culture in his country. For a great many years it has been the medium through which our ablest writers have made known their discoveries and observations.—*Address of L. P. Yandell, M.D., before International Med. Congress*, Sept. 1876.

And that it was specifically included in the award of a medal of merit to the Publishers in the Vienna Exhibition in 1873.

The subscription price of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" has never been raised during its long career. It is still FIVE DOLLARS per annum; and when paid for in advance, the subscriber receives in addition the "MEDICAL NEWS AND ABSTRACT," making in all nearly 2000 large octavo pages per annum, free of postage.

II.

THE MEDICAL NEWS AND ABSTRACT.

Thirty-seven years ago the "MEDICAL NEWS" was commenced as a monthly to convey to the subscribers of the "AMERICAN JOURNAL" the clinical instruction and current information which could not be accommodated in the Quarterly. It consisted of sixteen pages of such matter, together with sixteen more known as the Library Department and devoted to the publishing of books. With the increased progress of science, however, this was found insufficient, and some years since another periodical, known as the "MONTHLY ABSTRACT," was started, and was furnished at a moderate price to subscribers to the "AMERICAN JOURNAL." These two monthlies will hereafter be consolidated, under the title of "THE MEDICAL NEWS AND ABSTRACT," and will be furnished *free of charge* in connection with the "AMERICAN JOURNAL."

---

* Communications are invited from gentlemen in all parts of the country. Elaborate articles inserted by the Editor are paid for by the publishers.

The "NEWS AND ABSTRACT" consists of 64 pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, by gentlemen of the highest reputation throughout the United States, together with a choice selection of foreign Lectures and Hospital Notes and Gleanings. Then follows the MONTHLY ABSTRACT, systematically arranged and classified, and presenting five or six hundred articles yearly; and each number concludes with a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

As stated above, the subscription price to the "NEWS AND ABSTRACT" is Two Dollars and a Half per annum, invariably in advance, at which rate it ranks as one of the cheapest medical periodicals in the country. But it is also furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

In this effort to furnish so large an amount of practical information at a price so unprecedentedly low, and thus place it within the reach of every member of the profession, the publishers confidently anticipate the friendly aid of all who feel an interest in the dissemination of sound medical literature. They trust, especially, that the subscribers to the "AMERICAN MEDICAL JOURNAL," will call the attention of their acquaintances to the advantages thus offered, and that they will be sustained in the endeavor to permanently establish medical periodical literature on a footing of cheapness never heretofore attempted.

PREMIUM FOR OBTAINING NEW SUBSCRIBERS TO THE "JOURNAL."

Any gentleman who will remit the amount for two subscriptions for 1880, one of which at least must be for a *new subscriber*, will receive as a PREMIUM, free by mail, a copy of any one of the following recent works:—

- "SEILER ON THE THROAT" (see p. 19),
- "BARNES'S MANUAL OF MIDWIFERY" (see p. 24),
- "TILBURY FOX'S EPITOME OF DISEASES OF THE SKIN," new edition (see p. 18),
- "FOTHERGILL'S ANTAGONISM OF MEDICINES" (see p. 16),
- "HOLDEN'S LANDMARKS, MEDICAL AND SURGICAL" (see p. 6),
- "BROWNE ON THE USE OF THE OPHTHALMOSCOPE" (see p. 29),
- "FLINT'S ESSAYS ON CONSERVATIVE MEDICINE" (see p. 15),
- "STURGES'S CLINICAL MEDICINE" (see p. 14),
- "SWAYNE'S OBSTETRIC APHORISMS," new edition (see p. 21),
- "TANNER'S CLINICAL MANUAL" (see p. 5),
- "WEST ON NERVOUS DISORDERS OF CHILDREN" (see p. 20).

⁂ Gentlemen desiring to avail themselves of the advantages thus offered will do well to forward their subscriptions at an early day, in order to insure the receipt of complete sets for the year 1880.

☞ The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" may be made at the risk of the publishers, by forwarding in REGISTERED letters. Address,

HENRY C. LEA'S SON & CO., Nos. 706 and 708 Sansom St., Phila., Pa.

DUNGLISON (ROBLEY), M.D.,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: Containing a concise explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence, and Dentistry. Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical, and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes; so as to constitute a French as well as English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly Modified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8. (*Just Issued.*)

The object of the author from the outset has not been to make the work a mere lexicon or dictionary of terms, but to afford, under each, a condensed view of its various medical relations, and thus to render the work an epitome of the existing condition of medical science. Starting with this view, the immense demand which has existed for the work has enabled him, in repeated revisions, to augment its completeness and usefulness, until at length it has attained the position of a recognized and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain this enviable reputation. During the ten years which have elapsed since the last revision, the additions to the nomenclature of the medical sciences have been greater than perhaps in any similar period of the past, and up to the time of his death the author labored assiduously to incorporate everything requiring the attention of the student or practitioner. Since then, the editor has been equally industrious, so that the additions to the vocabulary are more numerous than in any previous revision. Especial attention has been bestowed on the accentuation, which will be found marked on every word. The typographical arrangement has been much improved, rendering reference much more easy, and every care has been taken with the mechanical execution. The work has been printed on new type, small but exceedingly clear, with an enlarged page, so that the additions have been incorporated with an increase of but little over a hundred pages, and the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan. 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the editor "that the work, which possesses for him a filial as well as an individual interest, will be found worthy a continuance of the position so long accorded to it as a standard authority."—*Cincinnati Clinic*, Jan. 10, 1874.

It has the rare merit that it certainly has no rival in the English language for accuracy and extent of references.—*London Medical Gazette*

As a standard work of reference, as one of the best, if not the very best, medical dictionary in the English language, Dunglison's work has been well known for about forty years, and needs no words of praise on our part to recommend it to the members of the medical, and, likewise, of the pharmaceutical profession. The latter especially are in need of such a work, which gives ready and reliable information on thousands of subjects and terms which they are liable to encounter in pursuing their daily avocations, but with which they cannot be expected to be familiar. The work before us fully supplies this want.—*Am. Journ. of Pharm.*, Feb. 1874.

A valuable dictionary of the terms employed in medicine and the allied sciences, and of the relations of the subjects treated under each head. It reflects great credit on its able American author, and well deserves the authority and popularity it has obtained.—*British Med. Journ.*, Oct. 31, 1874.

Few works of this class exhibit a grander monument of patient research and of scientific lore. The extent of the sale of this lexicon is sufficient to testify to its usefulness, and to the great service conferred by Dr. Robley Dunglison on the profession, and indeed on others, by its issue.—*London Lancet*, May 13 1876.

HOBLYN (RICHARD D.), M.D.

A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES. Revised, with numerous additions, by ISAAC HAYS, M.D., Editor of the "American Journal of the Medical Sciences." In one large royal 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00

It is the best book of definitions we have, and ought always to be upon the student's table.—*Southern Med. and Surg. Journal.*

RODWELL (G. F.), F.R.A.S., &c.

A DICTIONARY OF SCIENCE: Comprising Astronomy, Chemistry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magnetism, Mechanics, Meteorology, Pneumatics, Sound, and Statics. Preceded by an Essay on the History of the Physical Sciences. In one handsome octavo volume of 694 pages, and many illustrations: cloth, $5.

A *CENTURY OF AMERICAN MEDICINE*, 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas, and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25. (*Lately Issued.*)

This work appeared in the pages of the American Journal of the Medical Sciences during the year 1876. As a detailed account of the development of medical science in America, by gentlemen of the highest authority in their respective departments, the profession will no doubt welcome it in a form adapted for preservation and reference.

NEILL (JOHN), M.D., and SMITH (FRANCIS G.), M.D.,
Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE;

for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

HARTSHORNE (HENRY), M.D.,
Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES;

containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery, and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00. (*Lately Issued.*)

We can say with the strictest truth that it is the best work of the kind with which we are acquainted. It embodies in a condensed form all recent contributions to practical medicine, and is therefore useful to every busy practitioner throughout our country, besides being admirably adapted to the use of students of medicine. The book is faithfully and ably executed.—*Charleston Med. Journ.*, April, 1875.

The work is intended as an aid to the medical student, and as such appears to admirably fulfil its object by its excellent arrangement, the full compilation of facts, the perspicuity and terseness of language, and the clear and instructive illustrations in some parts of the work.—*American Journ. of Pharmacy*, Philadelphia, July, 1874.

The volume will be found useful, not only to students, but to many others who may desire to refresh their memories with the smallest possible expenditure of time.—*N. Y. Med. Journal*, Sept. 1874.

The student will find this the most convenient and useful book of the kind on which he can lay his hand.—*Pacific Med. and Surg. Journ.*, Aug. 1874.

This is the best book of its kind that we have ever examined. It is an honest, accurate, and concise compend of medical sciences, as fairly as possible representing their present condition. The changes and the additions have been so judicious and thorough as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr. Hartshorne.—*Detroit Rev. of Med. and Pharm.*, Aug. 1874.

The work before us, however, has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation. It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the latest advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept. 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874

LUDLOW (J. L.), M.D.

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology,

Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy, and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations. In one handsome royal 12mo. volume of 816 large pages, cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suitable for the office examination of students, and for those preparing for graduation.

TANNER (THOMAS HAWKES), M.D., &c.

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS.

Third American from the Second London Edition. Revised and Enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, &c. In one neat volume small 12mo., of about 375 pages, cloth, $1 50.

*** On page 3, it will be seen that this work is offered as a premium for procuring new subscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

GRAY (HENRY), F.R.S.,

Lecturer on Anatomy at St. George's Hospital; London.

ANATOMY, DESCRIPTIVE AND SURGICAL. The Drawings by H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the AUTHOR and Dr. CARTER. With an Introduction on General Anatomy and Development by T. HOLMES, M.A., Surgeon to St. George's Hospital. A new American, from the eighth enlarged and improved London edition. To which is added "LANDMARKS, MEDICAL AND SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Manual of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, with 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, $7; half Russia, $7 50. (*Just Ready.*)

The author has endeavored in this work to cover a more extended range of subjects than is customary in the ordinary text-books, by giving not only the details necessary for the student, but also the application of those details in the practice of medicine and surgery, thus rendering it both a guide for the learner, and an admirable work of reference for the active practitioner. The engravings form a special feature in the work, many of them being the size of nature, nearly all original, and having the names of the various parts printed on the body of the cut, in place of figures of reference, with descriptions at the foot. They thus form a complete and splendid series, which will greatly assist the student in obtaining a clear idea of Anatomy, and will also serve to refresh the memory of those who may find in the exigencies of practice the necessity of recalling the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, with a thorough treatise on systematic, descriptive, and applied Anatomy, the work will be found of essential use to all physicians who receive students in their offices, relieving both preceptor and pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions at the hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has seemed requisite to maintain its reputation as a complete and authoritative standard text-book and work of reference. Still further to increase its usefulness, there has been appended to it the recent work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Surgical"—which gives in a clear, condensed, and systematic way, all the information by which the practitioner can determine from the external surface of the body the position of internal parts. Thus complete, the work, it is believed, will furnish all the assistance that can be rendered by type and illustration in anatomical study. No pains have been spared in the typographical execution of the volume, which will be found in all respects superior to former issues. Notwithstanding the increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as heretofore, at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr. Holden, which was noticed by us on p. 53 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable edition of Mr Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug. 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical*," which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The work is simply indispensable, especially this present American edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. Holden, as an appendix, renders this the most practical and complete treatise available to American students, who find in it a comprehensive chapter on minute anatomy, about all that can be taught on general and special anatomy, while its treatment of each region, from a surgical point of view, in the valuable section by Mr. Holden, is all that will be essential to them in practice.—*Ohio Medical Recorder*, Aug. 1878.

It is difficult to speak in moderate terms of this new edition of "Gray." It seems to be as nearly perfect as it is possible to make a book devoted to any branch of medical science. The labors of the eminent men who have successively revised the eight editions through which it has passed, would seem to leave nothing for future editors to do. The addition of Holden's "Landmarks" will make it as indispensable to the practitioner of medicine and surgery as it has been heretofore to the student. As regards completeness, ease of reference, utility, beauty, and cheapness, it has no rival. No student should enter a medical school without it; no physician can afford to have it absent from his library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,

Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL. From the 2d London Ed. In one handsome volume, royal 12mo., of 128 pages: cloth, 88 cents. (*Now Ready.*)

HEATH (CHRISTOPHER), F.R.C.S.,

Teacher of Operative Surgery in University College, London.

PRACTICAL ANATOMY: A Manual of Dissections. From the Second revised and improved London edition. Edited, with additions, by W. W. KEEN, M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philadelphia. In one handsome royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3 50; leather, $4 00.

ALLEN (HARRISON), M.D.

Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY; INCLUDING ITS MEDICAL and Surgical Relations. For the Use of Practitioners and Students of Medicine. With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M. D., Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. (*In Press.*)

In this elaborate work, which has been in active preparation for several years, the author has sought to give, not only the details of descriptive anatomy in a clear and condensed form, but also the practical applications of the science to medicine and surgery. The work thus has claims upon the attention of the general practitioner, as well as of the student, enabling him not only to refresh his recollections of the dissecting room, but also to recognize the significance of all variations from normal conditions. The marked utility of the object thus sought by the author is self-evident, and his long experience and assiduous devotion to its thorough development are a sufficient guarantee of the manner in which his aims have been carried out. No pains have been spared with the illustrations. Those of normal anatomy are from original dissections, drawn on stone by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, after the manner of "Holden" and "Gray," and in every typographical detail it will be the effort of the publisher to render the volume worthy of the very distinguished position which is anticipated for it.

ELLIS (GEORGE VINER).

Emeritus Professor of Anatomy in University College, London.

DEMONSTRATIONS OF ANATOMY; Being a Guide to the Knowledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25. (*Just Ready.*)

This work has long been known in England as the leading authority on practical anatomy, and the favorite guide in the dissecting-room, as is attested by the numerous editions through which it has passed. In the last revision, which has just appeared in London, the accomplished author has sought to bring it on a level with the most recent advances of science by making the necessary changes in his account of the microscopic structure of the different organs, as developed by the latest researches in textural anatomy.

Ellis's Demonstrations is the favorite text-book of the English student of anatomy. In passing through eight editions it has been so revised and adapted to the needs of the student that it would seem that it had almost reached perfection in this special line. The descriptions are clear, and the methods of pursuing anatomical investigations are given with such detail that the book is honestly entitled to its name.—*St. Louis Clinical Record*, June, 1879.

The success of this old manual seems to be as well deserved in the present as in the past volumes. The book seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

WILSON (ERASMUS), F.R.S.

A SYSTEM OF HUMAN ANATOMY, General and Special. Edited by W. H. GOBRECHT, M.D., Professor of General and Surgical Anatomy in the Medical College of Ohio. Illustrated with three hundred and ninety-seven engravings on wood. In one large and handsome octavo volume, of over 600 large pages; cloth, $4; leather, $5.

SMITH (HENRY H.), M.D., and HORNER (WILLIAM E.), M.D.,

Prof. of Surgery in the Univ. of Penna., &c. *Late Prof. of Anatomy in the Univ. of Penna.*

AN ANATOMICAL ATLAS; illustrative of the Structure of the Human Body. In one volume, large imperial octavo, cloth, with about six hundred and fifty beautiful figures. $4 50.

SCHAFER (EDWARD ALBERT), M.D.,

Assistant Professor of Physiology in University College, London.

A COURSE OF PRACTICAL HISTOLOGY: Being an Introduction to the Use of the Microscope. In one handsome royal 12mo. volume of 304 pages, with numerous illustrations: cloth, $2 00. (*Just Issued.*)

HORNER'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified. In 2 vols. 8vo., of over 1000 pages, with 320 wood-cuts: cloth, $6 00.

SHARPEY AND QUAIN'S HUMAN ANATOMY. Revised, by JOSEPH LEIDY, M.D., Prof of Anat. in Univ. of Penn. In two octavo vols. of about 1300 pages, with 511 illustrations. Cloth, $6 00.

BELLAMY'S STUDENT'S GUIDE TO SURGICAL ANATOMY: A Text book for Students preparing for their Pass Examination. With engravings on wood. In one handsome royal 12mo. volume. Cloth, $2 25.

CLELAND'S DIRECTORY FOR THE DISSECTION OF THE HUMAN BODY. In one small volume, royal 12mo. of 182 pages: cloth $1 25.

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. vol., with 220 wood cuts cloth, $1 75.

CARPENTER (WILLIAM B.), M. D., F. R. S., F. G. S., F. L. S.,
Registrar to University of London, etc.

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWER, M.B. Lond., F R.C.S., Examiner in Natural Sciences, University of Oxford. A new American from the Eighth Revised and Enlarged English Edition, with Notes and Additions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the University of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pages, with two plates and 373 engravings on wood; cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Issued.*)

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears. The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago. looks now as if it had been a received and established fact for years. In this encyclopædic way it is unrivalled. Here, as it seems to us, is the great value of the book; one is safe in sending a student to it for information on almost any given subject, perfectly certain of the fulness of information it will convey, and well satisfied of the accuracy with which it will there be found stated.—*London Med. Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work. In fact the entire work has been brought up to date, and bears evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med. Journal*, Jan. 1877.

FOSTER (MICHAEL), M.D., F.R.S.,
Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. A new American, from the last English edition. Edited with notes and additions by EDWARD T. REICHERT, M.D., Demonstrator of Experimental Therapeutics in Univ. of Penna. In one handsome royal 12mo. volume of 1030 pages, with 259 illustrations. Cloth, $3 00. Leather, $3 50. (*Just Ready.*)

AMERICAN EDITOR'S PREFACE.

The high reputation acquired on both sides of the Atlantic by Dr. Foster's "Text-Book on Physiology," as a lucid exposition of functional physiology, in its most modern aspect, has seemed to call for an edition more thoroughly adapted to the wants of the American student. The plan of the author has presupposed an acquaintance with the details of physiological anatomy such as the student is accustomed to look to in his treatises on physiology. The absence of these details has rendered many parts of the work vague, if not altogether incomprehensible, and has therefore proved a serious drawback to the usefulness of the book as an accompaniment to lectures on physiology, as it is usually taught in our schools, and this deficiency the editor has endeavored to supply, by brief notes and the introduction of a large number of illustrations.

The almost limitless amount of material accumulated by modern research has rendered difficult the task of selection and compression, without exceeding the reasonable limits of a convenient text-book. In his selection the editor has been guided by his experience in the wants of students, and has endeavored merely to present, in the most concise form, such facts as would seem to be indispensable to a correct appreciation of the structure and function of the important organs. In accomplishing this, his additions have considerably exceeded his expectations, amounting to about 140 pages, including the illustrations which have been increased in number from 72 to 259. If he shall thus have succeeded in rendering this admirable work better fitted for the wants of the American student, he will feel abundantly rewarded.

Nothing has been omitted from the English edition, and all additions have been distinguished by insertions in brackets [—].

The great popularity of "Foster's Text-book of Physiology," both in England and in this country, renders it unnecessary to say anything further regarding its merit. We shall, therefore, simply point out that, in the American edition, numerous important additions have been made to the text of the third English edition whereby the usefulness of the work as a text-book for students has been greatly increased.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

The additions of the American editor are so copious and important as to largely increase the book's sphere of usefulness. In notices of former editions, we alluded to the absence of any reference to the physiological anatomy of the different organs, and the dearth of illustrations as serious drawbacks to the value and general usefulness of Dr. Foster's work. These faults of omission have been intelligently and quite fully supplied by the American editor. So ably and so thoroughly has the editor performed his task, that we have no hesitancy in saying that, in our opinion, the American edition is far superior to its English contemporary. In its present form we confidently recommend this text-book to the student as a clear, concise, and thoroughly reliable exposition of modern physiology.—*Am. Journ. of Med Sciences*, July, 1880.

The matter of the last English edition has been transferred bodily to this, and there have been added very many illustrations and copious notes on histology and embryology by the American editor. The English editions have been defective, so far as American students are concerned, in their dearth of illustrations and the absence of all discussion of physiological anatomy. These being supplied in this edition, the work is now undoubtedly the best on physiology in the English language.—*Ohio Med. Recorder*, June, 1880.

THE SAME. English Student's Edition, without notes or additions. Latest issue. In one 12mo. volume of 804 pages with 72 illustrations. Cloth, $3 00.

DALTON (J. C.), M.D.,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Sixth edition, thoroughly revised and enlarged, with three hundred and sixteen illustrations on wood. In one very beautiful octavo volume, of over 800 pages. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

During the past few years several new works on physiology, and new editions of old works, have appeared, competing for the favor of the medical student, but none will rival this new edition of Dalton. As now enlarged, it will be found also to be, in general, a satisfactory work of reference for the practitioner.—*Chicago Med. Journ. and Examiner*, Jan. 1876.

Prof. Dalton has discussed conflicting theories and conclusions regarding physiological questions with a fairness, a fulness, and a conciseness which lend freshness and vigor to the entire book. But his discussions have been so guarded by a refusal of admission to those speculative and theoretical explanations, which at best exist in the minds of observers themselves as only probabilities, that none of his readers need be led into grave errors while making them a study.—*The Medical Record*, Feb. 19, 1876.

The revision of this great work has brought it forward with the physiological advances of the day, and renders it, as it has ever been, the finest work for students extant.—*Nashville Journ. of Med. and Surg.*, Jan. 1876.

For clearness and perspicuity, Dalton's Physiology commended itself to the student years ago. and was a pleasant relief from the verbose productions which it supplanted. Physiology has, however. made many advances since then—and while the style has been preserved intact, the work in the present edition has been brought up fully abreast of the times. The new chemical notation and nomenclature have also been introduced into the present edition. Notwithstanding the multiplicity of text-books on physiology. this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent. of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realized. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ.*, Dec. 1875.

We heartily welcome this, the sixth edition of this admirable text book. than which there are none of equal brevity more valuable. It is cordially recommended by the Professor of Physiology in the University of Louisiana, as by all competent teachers in the United States, and wherever the English language is read, this book has been appreciated. The present edition, with its 316 admirably executed illustrations. has been carefully revised and very much enlarged, although its bulk does not seem perceptibly increased.—*New Orleans Medical and Surgical Journal*, March, 1876.

GREENE (WILLIAM H.), M.D.,

Demonstrator of Chemistry in Med. Dept., Univ. of Penna.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students. Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages. With illustrations. Cloth, $1 75. (*Just Issued.*)

It is well written, and gives the latest views on vital chemistry, a subject with which most physicians are not sufficiently familiar. To those who may wish to improve their knowledge in that direction, we can heartily recommend this work as being worthy of a careful perusal.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit. The descriptions, though brief, are clear, and in most cases sufficient for the purpose This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

CLASSEN (ALEXANDER),

Professor in the Royal Polytechnic School, Aix la-Chapelle.

ELEMENTARY QUANTITATIVE ANALYSIS. Translated with notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Just Ready.*)

It is probably the best manual of an elementary nature extant, insomuch as its methods are the best. It teaches by examples, commencing with single determinations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

GALLOWAY (ROBERT), F.C.S.,

Prof of Applied Chemistry in the Royal College of Science for Ireland, etc.

A MANUAL OF QUALITATIVE ANALYSIS. From the Fifth London Edition. In one neat royal 12mo. volume, with illustrations; cloth, $2 75. (*Lately Issued.*)

REMSEN (IRA), M.D., Ph.D.,

Professor of Chemistry in the Johns Hopkins University, Baltimore.

PRINCIPLES OF THEORETICAL CHEMISTRY, with special reference to the Constitution of Chemical Compounds. In one handsome royal 12mo. vol. of over 232 pages: cloth, $1 50. (*Just Issued.*)

BOWMAN'S INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. Sixth American, from the sixth and revised London edition With numerous illustrations. In one neat vol., royal 12mo., cloth, $2 25.

WOHLER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY. Translated with additions from the Eighth German Edition. By IRA REMSEN. M D, Ph.D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 550 pp, cloth. $3.

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M.D. With illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1200 pages, with 200 illustrations; cloth, $6.

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical. Revised and corrected by Henry Watts, B.A., F R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illustrations. A new American, from the twelfth and enlarged London edition. Edited by Robert Bridges, M.D. In one large royal 12mo. volume, of over 1000 pages; cloth, $2 75; leather, $3 25. (*Just Issued.*)

Two careful revisions by Mr. Watts, since the appearance of the last American edition of "Fownes," have so enlarged the work that in England it has been divided into two volumes. In reprinting it, by the use of a small and exceedingly clear type, cast for the purpose, it has been found possible to comprise the whole, without omission, in one volume, not unhandy for study and reference. The enlargement of the work has induced the American Editor to confine his additions to the narrowest compass, and he has accordingly inserted only such discoveries as have been announced since the very recent appearance of the work in England, and has added the standards in popular use to the Decimal and Centigrade systems employed in the original.

Among the additions to this edition will be found a very handsome colored plate, representing a number of spectra in the spectroscope. Every care has been taken in the typographical execution to render the volume worthy in every respect of its high reputation and extended use, and though it has been enlarged by more than one hundred and fifty pages, its very moderate price will still maintain it as one of the cheapest volumes accessible to the chemical student.

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more than a thousand pages, but with less than this no fair representation of chemistry as it now is can be given. The type is small but very clear, and the sections are very lucidly arranged to facilitate study and reference.—*Med and Surg. Reporter*, Aug 3, 1878.

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former *prestige.*—*Boston Jour. of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make any remarks relating to the general character of Fownes' Manual. For over twenty years it has held *the* foremost place as a text-book, and the elaborate and thorough revisions which have been made from time to time leave little chance for any wide awake rival to step before it.—*Canadian Pharm. Jour.*, Aug. 1878.

As a manual of chemistry it is without a superior in the language.—*Md. Med. Jour.*, Aug. 1878.

ATTFIELD (JOHN), Ph.D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL, AND PHARMACEUTICAL; including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, $2 50; leather, $3 00. (*Just Ready.*)

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it, little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*Am. Jour. of Pharmacy*, May, 1879.

A standard work like Attfield's Chemistry need only be mentioned by its name, without further comments The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. The author has bestowed arduous labor on the revision, and the extent of the information thus introduced may be estimated from the fact that the index contains three hundred new references relating to additional material.—*Druggists' Circular and Chemical Gazette*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges in the United States. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Cincinnati Medical News*, April, 1879.

The popularity which this work has enjoyed is owing to the original and clear disposition of the facts of the science, the accuracy of the details, and the omission of much which freights many treatises heavily without bringing corresponding instruction to the reader. Dr. Attfield writes for students, and primarily for medical students; he always has an eye to the pharmacopœia and its officinal preparations; and he is continually putting the matter in the text so that it responds to the questions with which each section is provided. Thus the student learns easily, and can always refresh and test his knowledge.—*Med. and Surg. Reporter*, April 19, '79.

We noticed only about two years and a half ago the publication of the preceding edition, and remarked upon the exceptionally valuable character of the work. The work now includes the whole of the chemistry of the pharmacopœia of the United States, Great Britain, and India.—*New Remedies*, May, 1879.

BLOXAM (*C. L.*),

Professor of Chemistry in King's College, London.

CHEMISTRY, INORGANIC AND ORGANIC. From the Second London Edition. In one very handsome octavo volume, of 700 pages, with about 300 illustrations. Cloth, $4 00; leather, $5 00. (*Lately Issued.*)

We have in this work a complete and most excellent text-book for the use of schools, and can heartily recommend it as such.—*Boston Med. and Surg. Journ.*, May 28, 1874.

The above is the title of a work which we can most conscientiously recommend to students of chemistry. It is as easy as a work on chemistry could be made, at the same time that it presents a full account of that science as it now stands. We have spoken of the work as admirably adapted to the wants of students; it is quite as well suited to the requirements of practitioners who wish to review their chemistry, or have occasion to refresh their memories on any point relating to it. In a word, it is a book to be read by all who wish to know what is the chemistry of the present day.—*American Practitioner*, Nov. 1873.

It would be difficult for a practical chemist and teacher to find any material fault with this most admirable treatise. The author has given us almost a cyclopædia within the limits of a convenient volume, and has done so without penning the useless paragraphs too commonly making up a great part of the bulk of many cumbrous works. The progressive scientist is not disappointed when he looks for the record of new and valuable processes and discoveries, while the cautious conservative does not find its pages monopolized by uncertain theories and speculations. A peculiar point of excellence is the crystallized form of expression in which great truths are expressed in very short paragraphs. One is surprised at the brief space allotted to an important topic, and yet, after reading it, he feels that little, if any more should have been said. Altogether, it is seldom you see a text-book so nearly faultless.—*Cincinnati Lancet* Nov. 1873.

CLOWES (*FRANK*), *D.Sc., London.*

Senior Science-Master at the High School, Newcastle-under-Lyme, etc.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS. Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. From the Second and Revised English Edition, with about fifty illustrations on wood. In one very handsome royal 12mo. volume of 372 pages: cloth, $2 50. (*Just Issued.*)

It is short, concise, and eminently practical. We therefore heartily commend it to students, and especially to those who are obliged to dispense with a master. Of course, a teacher is in every way desirable, but a good degree of technical skill and practical knowledge can be attained with no other instructor than the very valuable handbook now under consideration.—*St. Louis Clin. Record*, Oct. 1877.

The work is so written and arranged that it can be comprehended by the student without a teacher, and the descriptions and directions for the various work are so simple, and yet concise, as to be interesting and intelligible. The work is unincumbered with theoretical deductions, dealing wholly with the practical matter, which it is the aim of this comprehensive text-book to impart. The accuracy of the analytical methods are vouched for from the fact that they have all been worked through by the author and the members of his class, from the printed text. We can heartily recommend the work to the student of chemistry as being a reliable and comprehensive one.—*Druggists' Advertiser*, Oct. 15, 1877.

KNAPP'S TECHNOLOGY; or Chemistry Applied to the Arts, and to Manufactures. With American additions by Prof. WALTER R. JOHNSON. In two very handsome octavo volumes, with 500 wood engravings, cloth, $6 00.

PARRISH (*EDWARD*),

Late Professor of Materia Medica in the Philadelphia College of Pharmacy.

A TREATISE ON PHARMACY. Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Fourth Edition, thoroughly revised, by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations; cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

Of Dr. Parrish's great work on pharmacy it only remains to be said that the editor has accomplished his work so well as to maintain, in this fourth edition, the high standard of excellence which it had attained in previous editions, under the editorship of its accomplished author. This has not been accomplished without much labor, and many additions and improvements, involving changes in the arrangement of the several parts of the work, and the addition of much new matter. With the modifications thus effected it constitutes, as now presented, a compendium of the science and art indispensable to the pharmacist, and of the utmost value to every practitioner of medicine desirous of familiarizing himself with the pharmaceutical preparation of the articles which he prescribes for his patients.—*Chicago Med. Journ.*, July, 1874.

The work is eminently practical, and has the rare merit of being readable and interesting, while it preserves a strictly scientific character. The whole work reflects the greatest credit on author, editor and publisher. It will convey some idea of the liberality which has been bestowed upon its production when we mention that there are no less than 280 carefully executed illustrations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honored place on our own bookshelves.—*Dublin Med. Press and Circular*, Aug. 12, 1874.

We expressed our opinion of a former edition in terms of unqualified praise, and we are in no mood to detract from that opinion in reference to the present edition, the preparation of which has fallen into competent hands. It is a book with which no pharmacist can dispense, and from which no physician can fail to derive much information of value to him in practice.—*Pacific Med. and Surg. Journ.*, June, '74.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiegand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

FARQUHARSON (ROBERT), M.D.,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA. Second American edition, revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of 496 pages: cloth, $2 25. (*Just Ready.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ. of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodying the latest revision of the Pharmacopœia, together with the antidotes to the more prominent poisons, and such of the newer remedial agents as seemed necessary to the completeness of the work. Tables of weights and measures, and a good alphabetical index end the volume.—*Druggists' Circular and Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity with which a second edition is demanded may be taken as an indication that the sense of appreciation of the value of reliable information regarding the use of remedies is not entirely overwhelmed in the cultivation of pathological studies, characteristic of the present day. This work certainly merits the success it has so quickly achieved.—*New Remedies*, July, '78.

STILLÉ (ALFRED), M.D.,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treatise on the Action and Uses of Medicinal Agents, including their Description and History. Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of about 2000 pages. Cloth, $10; leather, $12; half Russia, $13. (*Lately Issued.*)

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct 1875.

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents, Dr. Stillé's is "*par excellence*" the work. The work being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely reissuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg. Journal*, Dec. 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia of therapeutics.—*Chicago Medical Journal*, Feb. 1875.

The rapid exhaustion of three editions and the universal favor with which the work has been received by the medical profession, are sufficient proof of its excellence as a repertory of practical and useful information for the physician. The edition before us fully sustains this verdict, as the work has been carefully revised and in some portions rewritten, bringing it up to the present time by the admission of chloral and croton-chloral, nitrite of amyl, bichloride of methylene, methylic ether, lithium compounds, gelseminum, and other remedies.—*Am. Journ. of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival in the multitude of its citations and the fulness of its research into clinical histories, and we must assign it a place in the physician's library; not, indeed, as fully representing the present state of knowledge in pharmacodynamics, but as by far the most complete treatise upon the clinical and practical side of the question.—*Boston Med. and Surg. Journal*, Nov. 4, 1874.

GRIFFITH (ROBERT E.), M.D.

A UNIVERSAL FORMULARY, Containing the Methods of Preparing and Administering Officinal and other Medicines. The whole adapted to Physicians and Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by JOHN M. MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume of about 800 pp., cl., $4 50; leather, $5 50. (*Lately Issued.*)

To the druggist a good formulary is simply indispensable, and perhaps no formulary has been more extensively used than the well-known work before us. Many physicians have to officiate, also, as druggists. This is true especially of the country physician, and a work which shall teach him the means by which to administer or combine his remedies in the most efficacious and pleasant manner, will always hold its place upon his shelf. A formulary of this kind is of benefit also to the city physician in largest practice.—*Cincinnati Clinic*, Feb. 21, 1874.

A more complete formulary than it is in its present form the pharmacist or physician could hardly desire. To the first some such work is indispensable, and it is hardly less essential to the practitioner who compounds his own medicines. Much of what is contained in the introduction ought to be committed to memory by every student of medicine. As a help to physicians it will be found invaluable, and doubtless will make its way into libraries not already supplied with a standard work of the kind.—*The American Practitioner*, Louisville, July, '74.

CHRISTISON'S DISPENSATORY. With copious additions, and 213 large wood engravings. By R. EGLESFIELD GRIFFITH, M.D. One vol. 8vo., pp. 1000, cloth. $4 00.

CARPENTER'S PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F. CONDIE, M.D., and explanations of scientific words. In one neat 12mo. volume, pp. 178, cloth. 60 cents.

STILLE (ALFRED), M.D., LL.D., *and* ***MAISCH (JOHN M.), Ph.D.,***

Prof. of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa.

Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready*)

Preface to the Second Edition.

The demand which has exhausted in a few months an unusually large edition of the National Dispensatory is doubly gratifying to the authors, as showing that they were correct in thinking that the want of such a work was felt by the medical and pharmaceutical professions, and that their efforts to supply that want have been acceptable. This appreciation of their labors has stimulated them in the revision to render the volume more worthy of the very marked favor with which it has been received. The first edition of a work of such magnitude must necessarily be more or less imperfect; and though but little that is new and important has been brought to light in the short interval since its publication, yet the length of time during which it was passing through the press rendered the earlier portions more in arrears than the later. The opportunity for a revision has enabled the authors to scrutinize the work as a whole, and to introduce alterations and additions wherever there has seemed to be occasion for improvement or greater completeness. The principal changes to be noted are the introduction of several drugs under separate headings, and of a large number of drugs, chemicals, and pharmaceutical preparations classified as allied drugs and preparations under the heading of more important or better known articles: these additions comprise in part nearly the entire German Pharmacopœia and numerous articles from the French Codex. All new investigations which came to the authors' notice up to the time of publication have received due consideration.

The series of illustrations has undergone a corresponding thorough revision. A number have been added, and still more have been substituted for such as were deemed less satisfactory.

The new matter embraced in the text is equal to nearly one hundred pages of the first edition. Considerable as are these changes as a whole, they have been accommodated by an enlargement of the page without increasing unduly the size of the volume.

While numerous additions have been made to the sections which relate to the physiological action of medicines and their use in the treatment of disease, great care has been taken to make them as concise as was possible without rendering them incomplete or obscure. The doses have been expressed in the terms both of troy weight and of the metrical system, for the purpose of making those who employ the Dispensatory familiar with the latter, and paving the way for its introduction into general use.

The Therapeutical Index has been extended by about 2250 new references, making the total number in the present edition about 6900.

The articles there enumerated as remedies for particular diseases are not only those which, in the authors' opinion, are curative, or even beneficial, but those also which have at any time been employed on the ground of popular belief or professional authority. It is often of as much consequence to be acquainted with the worthlessness of certain medicines or with the narrow limits of their power, as to know the well attested virtues of others and the conditions under which they are displayed. An additional value possessed by such an Index is, that it contains the elements of a natural classification of medicines, founded upon an analysis of the results of experience, which is the only safe guide in the treatment of disease.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a *second* edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

CORNIL (V.), *AND* *RANVIER (L.).*

Prof. in the Faculty of Med., Paris. *Prof in the College of France.*

MANUAL OF PATHOLOGICAL HISTOLOGY.

Translated, with Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surgeon to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Penna., and by HENRY C. SIMES, M.D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

The work of Cornil and Ranvier is so well known as a lucid and accurate text-book on its important subject, that no apology is needed in presenting a translation of it to the American profession. It is only necessary to say that the labors of Drs. Shakespeare and Simes have been by no means confined to the task of rendering the work into English. As it appeared in France, in successive portions, between 1868 and 1876, a part of it, at least, was somewhat in arrears of the present state of science, while the diffuseness of other portions rendered condensation desirable. The translators have, therefore, sought to bring the work up to the day, and, at the same time, to reduce it in size, as far as practicable, without impairing its completeness These changes will be found throughout the volume, the most extensive being in the sections devoted to Sarcoma, Carcinoma, Tuberculosis, the Bloodvessels, the Mamma, and the classification of tumors. Corresponding modifications have been made in the very extensive and beautiful series of illustrations, and every care has been taken in the typographical execution to render it one of the most attractive volumes which have issued from the American press.

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology" as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1880.

This important work, in its American dress, is a welcome offering to all students of the subjects which it treats. The great mass of material is arranged naturally and comprehensively. The classification of tumors is clear and full, so far as the subject admits of definition and this one chapter is worth the price of the book. The illustrations are copious and well chosen. Without the slightest hesitation, the translators deserve honest thanks for placing this indispensable work in the hands of American students.—*Phila. Med. Times*, April 24, 1880

This volume we cordially commend to the profession. It will prove a valuable, almost necessary, addition to the libraries of students who are to be physicians, and to the libraries of students who are physicians.—*American Practitioner*, June, 1880.

Their book is not a collection of the work of others, but has been written in the laboratory beside the microscope. It bears the marks of personal knowledge and investigation upon every page, controlled by and controlling the work of others. . . . In short, its translation has made it the best work in pathology attainable in our language, one that every student certainly ought to have.—*Archives of Medicine*, April, 1880.

This work, in the original, has for years past occupied a prominent place in the library of French pathologists, as we should naturally be led to believe from the reputation of the distinguished authors. Now that it has been presented to the English student for the first time, it will be perused with unusual interest. The illustrations are by no means the least valuable part of the work. Indispensable as they are to any work of this nature, in the work before us the artist has succeeded in producing cuts which will prove unusually valuable to the reader. The translation is well done, and gives evidence throughout the volume that it was made by a person thoroughly conversant with the subject.—*N. Y. Med. Gazette*, Feb. 28, 1880.

FENWICK (SAMUEL), M.D.,

Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS.

From the Third Revised and Enlarged English Edition. With eighty-four illustrations on wood. In one very handsome volume, royal 12mo., cloth, $2 25. (*Just Issued.*)

GREEN (T. HENRY), M.D.,

Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School, &c.

PATHOLOGY AND MORBID ANATOMY:

Third American, from the Fourth and Enlarged and Revised English Edition. In one very handsome octavo volume of 332 pages, with 132 illustrations; cloth, $2 25. (*Now Ready.*)

This is unquestionably one of the best manuals on the subject of pathology and morbid anatomy that can be placed in the student's hands, and we are glad to see it kept up to the times by new editions. Each edition is carefully revised by the author, with the view of making it include the most recent advances in pathology, and of omitting whatever may have become obsolete.—*N. Y. Med. Jour.*, Feb. 1879.

The treatise of Dr. Green is compact, clearly expressed, up to the times, and popular as a text-book, both in England and America. The cuts are sufficiently numerous, and usually well made. In the present edition, such new matter has been added as was necessary to embrace the later results in pathological research. No doubt it will continue to enjoy the favor it has received at the hands of the profession.—*Med and Surg. Reporter*, Feb. 1, 1879.

For practical, ordinary daily use, this is undoubtedly the best treatise that is offered to students of pathology and morbid anatomy.—*Cincinnati Lancet and Clinic*, Feb. 8, 1879.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY Translated, with Notes and Additions, by JOSEPH LEIDY, M.D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION: its Disorders and their Treatment. From the second London edition. In one handsome volume, small octavo, cloth, $2 00.

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological, and Therapeutical Relations. In two large and handsome octavo volumes of nearly 1500 pp., cloth. $7 00.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. 1 vol. 8vo., pp. 500; cloth. $3 50.

BARLOW'S MANUAL OF THE PRACTICE OF MEDICINE. With Additions by D. F. CONDIE, M.D. 1 vol. 8vo., pp 600, cloth. $2 50.

TODD'S CLINICAL LECTURES ON CERTAIN ACUTE DISEASES. In one neat octavo volume, of 320 pp., cloth. $2 50.

STOKES' LECTURES ON FEVER. Edited by JOHN WILLIAM MOORE, M.D., Assistant Physician to the Cork Street Fever Hospital. In one neat 8vo. volume cloth, $2 00.

FLINT (AUSTIN), M.D.,
Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the use of Students and Practitioners of Medicine. Fifth edition, entirely rewritten and much improved. In one large and closely printed octavo volume of about 1100 pp. (*Very shortly.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

In preparing the fifth edition of this treatise, the author has been thoroughly mindful of the progress of medicine since the publication of the fourth edition in 1873. Time and labor have not been spared in the endeavor to bring the work in all respects up to the present state of medical knowledge.

Dr. William H. Welch, Lecturer on Pathological Histology in the Bellevue Hospital Medical College, has contributed in Part I. the first seven chapters, embracing the general pathology of the solid tissues and of the blood. He has also revised, and in great part rewritten, the descriptions of the anatomical characters of the diseases considered in the rest of the volume. It is believed that these portions of the work will serve as a digest of the essential facts pertaining to general and special pathological anatomy, as far as this important branch of study bears upon practical medicine.

In the other portions of the treatise many changes will be found, which have somewhat enlarged the size of the volume, in spite of the omission of a considerable amount of matter, and the rewriting of many portions with a special view to condensation. Among these changes may be mentioned numerous improvements in the arrangement, including the classification of the diseases of the nervous system on an anatomical in place of a symptomatic basis, and the consideration of various diseases not embraced in previous editions. In short, the eliminations, substitutions, and additions render the present edition virtually a new work.

In making changes, the author has not been influenced by any sense of obligation to maintain consistency of views with the previous editions of this treatise, or with other works which he has written. If statements be found to vary from those made at a prior date, the simple explanation is that the latter, in the light of more recent reflection and enlarged knowledge, seems to him no longer tenable. He has endeavored to regard his own past writings, in this point of view, divested of the partiality of authorship, and to subject them to as critical an examination as if they were the writings of another.

BY THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*S. Louis Clin. Record*, Oct. 1879.

It is here that the skill and learning of the great clinician are displayed. He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879.

ESSAYS ON CONSERVATIVE MEDICINE AND KINDRED TOPICS. In one very handsome royal 12mo. volume. Cloth, $1 38. (*Just Issued.*)

WATSON (THOMAS), M.D., &c.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. Delivered at King's College, London. A new American, from the Fifth revised and enlarged English edition. Edited, with additions, and several hundred illustrations, by HENRY HARTSHORNE, M.D., Professor of Hygiene in the University of Pennsylvania. In two large and handsome 8vo. vols. Cloth, $9 00; leather, $11 00. (*Lately Published.*)

HARTSHORNE (HENRY), M.D.,
Professor of Hygiene in the University of Pennsylvania

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. A handy-book for Students and Practitioners. Fourth edition, revised and improved. With about one hundred illustrations. In one handsome royal 12mo. volume, of about 550 pages, cloth, $2 63; half bound, $2 88. (*Lately Issued.*)

DAVIS'S CLINICAL LECTURES ON VARIOUS IMPORTANT DISEASES; being a collection of the Clinical Lectures delivered in the Medical Wards of Mercy Hospital, Chicago. Edited by FRANK H DAVIS, M.D. Second edition, enlarged. In one handsome royal 12mo. volume. Cloth, $1 75.

THE CYCLOPÆDIA OF PRACTICAL MEDICINE: comprising Treatises on the Nature and Treatment of Diseases, Materia Medica and Therapeutics, Diseases of Women and Children, Medical Jurisprudence, etc. etc. By DUNGLISON, FORBES, TWEEDIE, and CONOLLY. In four large super-royal octavo volumes, of 3254 double-columned pages, strongly and handsomely bound in leather, $15; cloth, $11.

STURGES'S INTRODUCTION TO THE STUDY OF CLINICAL MEDICINE. Being a Guide to the Investigation of Disease. In one handsome 12mo. volume, cloth, $1 25. (*Lately Issued.*)

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,
Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE. Second American edition, revised by the Author. Edited, with Additions, by JAMES H. HUTCHINSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half Russia, $6 50. (*Now Ready.*)

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science. The chapter on diseases of the skin and of the nervous system, with a new one on insanity compiled from the best sources outside of the author's own long experience, and the valuable portion relating to general pathology, aid greatly in completing an exceptionally good book for purposes of reference and instruction —*Boston Medical and Surgical Journal*, February, 1880.

What we said of the first edition, we can, with increased emphasis, repeat concerning this: "Every page is characterized by the utterances of a thoughtful man. What has been said, has been well said, and the book is a fair reflex of all that is *certainly known* on the subjects considered."—*Ohio Med. Recorder*, Jan. 7, 1880.

RICHARDSON (BENJ. W.), M.D., F.R.S., M.A., LL.D., F.S.A.,
Fellow of the Royal College of Physicians, London.

PREVENTIVE MEDICINE. In one octavo volume of about 500 pages. (*In Press.*)

The immense strides taken by medical science during the last quarter of a century have had no more conspicuous field of progress than the causation of disease. Not only has this led to marked advance in therapeutics, but it has given rise to a virtually new department of medicine—the prevention of disease—more important, perhaps, in its ultimate results than even the investigation of curative processes. Yet thus far there has been no attempt to gather into a systematic and intelligible shape the accumulation of knowledge thus far acquired on this most interesting subject. Fortunately, the task has been at last undertaken by a writer who of all others is, perhaps, best qualified for its performance, and the result of his labors can hardly fail to mark an epoch in the history of medical science. The plan adopted for the execution of this novel design can best be explained in his own words:—

"With the object here expressed I write this volume. I have nothing to say in it that has any relation to the cure of disease, but I base it nevertheless on the curative side of medical learning. In other words, I trace the diseases from their actual representation as they exist before us, in their natural progress after their birth, as far as I am able, back to their origins, and try to seek the conditions out of which they spring. Thereupon I endeavor further to analyse those conditions, to see how far they are removable and how far they are avoidable."

FOTHERGILL (J. MILNER), M.D. Edin., M.R.C.P. Lond.,
Asst. Phys. to the West Lond Hosp.; Asst. Phys. to the City of Lond. Hosp., etc.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; Or, the Principles of Therapeutics. Second edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4 00; very handsome half Russia, $5 50. (*Just Ready.*)

The call for a second edition of Dr. Fothergill's work has been met by the author with a revision performed in no perfunctory manner. The entire subject-matter has been submitted to a most careful and exhaustive scrutiny, and much new material been added, including articles on "The Functional Disturbances of the Liver," "The Means of Acting on the Respiratory Nerve Centres," "The Reflex Consequences of Ovarian Irritation," "When Not to Give Iron," "Artificial Digestion," etc., thus presenting a complete reflex of the existing condition of therapeutical science.

BY THE SAME AUTHOR.

THE ANTAGONISM OF THERAPEUTIC AGENTS, AND WHAT IT TEACHES. Being the Fothergillian Prize Essay for 1878. In one neat volume, royal 12mo. of 156 pages; cloth, $1 00. (*Just Ready.*)

WOODBURY (FRANK), M.D.,
Physician to the German Hospital, Philadelphia, late Chief Assist. to Med. Clinic, Jeff. College Hospital, etc.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE OF Medicine; for the use of Students and Practitioners. Based upon Husband's Handbook of Practice. In one neat volume, royal 12mo. (*Preparing.*)

HABERSHON (S. O.) M.D.
Senior Physician to and late Lecturer on the Principles and Practice of Medicine at Guy's Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING THOSE of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines, and Peritoneum. Second American, from the third enlarged and revised English edition. With illustrations. In one handsome octavo volume of over 500 pages. Cloth, $3 50. (*Now Ready.*)

REYNOLDS (J. RUSSELL), M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE with Notes and Additions by Henry Hartshorne, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5.00; in sheep, $6.00: half Russia, raised bands, $6.50: Per set in cloth, $15; sheep, $18; half Russia, $19.50

Volume I. (*just ready*) contains General Diseases and Diseases of the Nervous System.

Volume II. (*just ready*) contains Diseases of Respiratory and Circulatory Systems.

Volume III. (*just ready*) contains Diseases of the Digestive and Blood Glandular Systems, of the Urinary Organs, of the Female Reproductive System, and of the Cutaneous System.

Reynolds's System of Medicine, recently completed, has acquired, since the first appearance of the first volume, the well-deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as for instance, Diseases of the Bladder by Sir Henry Thompson, Malpositions of the Uterus by Graily Hewitt, Insanity by Henry Maudsley, Consumption by J. Hughes Bennet, Diseases of the Spine by Charles Bland Radcliffe, Pericarditis by Francis Sibson, Alcoholism by Francis E. Anstie, Renal Affections by William Roberts, Asthma by Hyde Salter, Cerebral Affections by H Charlton Bastian, Gout and Rheumatism by Alfred Baring Garrod, Constitutional Syphilis by Jonathan Hutchinson, Diseases of the Stomach by Wilson Fox, Diseases of the Skin by Balmanno Squire, Affections of the Larynx by Morell Mackenzie, Diseases of the Rectum by Blizard Curling, Diabetes by Lauder Brunton, Intestinal Diseases by John Syer Bristowe, Catalepsy and Somnambulism by Thomas King Chambers, Apoplexy by J. Hughlings Jackson, Angina Pectoris by Professor Gairdner, Emphysema of the Lungs by Sir William Jenner, etc etc. All the leading schools in Great Britain have contributed their best men in generous rivalry, to build up this monument of medical science. St. Bartholomew's, Guy's, St Thomas's, University College, St Mary's in London, while the Edinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical School at Netley, the military and naval services, and the public health boards. That a work conceived in such a spirit, and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions are required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by Henry Hartshorne, M.D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

Really too much praise can scarcely be given to this noble book. It is a cyclopædia of medicine written by some of the best men of Europe. It is full of useful information such as one finds frequent need of in one's daily work As a book of reference it is invaluable. It is up with the times. It is clear and concentrated in style, and its form is worthy of its famous publisher.—*Louisville Med. News*, Jan. 31, 1880.

"Reynolds' System of Medicine" is justly considered the most popular work on the principles and practice of medicine in the English language The contributors to this work are gentlemen of well-known reputation on both sides of the Atlantic. Each gentleman has striven to make his part of the work as practical as possible, and the information contained is such as is needed by the busy practitioner.—*St Louis Med. and Surg. Journ.*, Jan. '80.

Dr. Hartshorne has made ample additions and revisions, all of which give increased value to the volume, and render it more useful to the American practitioner. There is no volume in English medical literature more valuable, and every purchaser will, on becoming familiar with it, congratulate himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar.—*Gaillard's Med. Journ.*, Feb. 1830

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

BARTHOLOW (ROBERTS), A.M., M.D., LL.D.

Prof. of Materia Medica and General Therapeutics in the Jeff. Med. Coll. of Phila., etc.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATION TO MEDICINE. In one very handsome octavo volume of about 450 pages, with illustrations. (*In press.*)

The constantly increasing therapeutic use of electricity, and the absence of a concise guide suited to the wants of the general practitioner, have induced the author to prepare the present volume. His object has been to present the most advanced state of existing knowledge in a form divested of unnecessary technicalities, keeping constantly in view the practical needs of the student and physician.

As the volume is founded upon a course of lectures delivered in the Jefferson Medical College during the spring of 1880, its adaptation to its purpose is insured. Dr. Bartholow's power of lucid exposition is well known, and is particularly desirable in a subject such as this, treated from the standpoint of the general practitioner and not of the specialist.

FINLAYSON (JAMES), M.D.,

Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.

CLINICAL DIAGNOSIS; A Handbook for Students and Practitioners of Medicine. In one handsome 12mo. volume, of 546 pages, with 86 illustrations. Cloth, $2 63. (*Just Issued.*)

The book is an excellent one, clear, concise, convenient, practical. It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan. 4, 1879.

This is one of the really useful books. It is attractive from preface to the final page, and ought to be given a place on every office table, because it contains in a condensed form all that is valuable in semeiology and diagnostics to be found in bulkier volumes, and because in its arrangement and complete index, it is unusually convenient for quick reference in any emergency that may come upon the busy practitioner. —*N. O. Med. Journ.*, Jan. 1879.

HAMILTON (ALLAN McLANE), M.D.,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N.Y., and at the Out-Patients' Department of the New York Hospital.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT. In one handsome octavo volume of 512 pages, with 53 illus.; cloth, $3 50. (*Just Issued.*)

CHARCOT (J. M.),

Professor to the Faculty of Med. Paris, Phys. to La Salpêtrière, etc.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM. Translated from the Second Edition by GEORGE SIGERSON, M.D., M.Ch., Lecturer on Biology, etc., Cath. Univ. of Ireland. With illustrations. 1 vol. 8vo. of 288 pages. Cloth, $1 75. (*Just Ready.*)

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS By C. HANDFIELD JONES, M.D., Physician to St. Mary's Hospital, &c. Second American Edition. In one handsome octavo volume of 348 pages, cloth, $3 25.

MORRIS (MALCOLM), M.D.,

Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Diagnosis, Prognosis, Morbid Anatomy, and Treatment. A Manual for Students and Practitioners. In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope, there is no book which for clearness of expression, and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has produced a plain, practical book, by aid of which, who so chooses may train his eye to the recognition of light but significant differences. The descriptions are neither too vague nor over-refined; the directions for treatment are clear and succinct.—*London Brain*, April, 1880.

The author has handled his subject in a clear and concise manner, and as a text-book to students his manual will be found useful.—*Medical and Surgical Reporter*, March 27, 1880.

The author's task has been well done and has produced one of the best recent works upon the difficult subject of which it treats; there is no work published which gives a better view of the elementary facts and principles of dermatology.—*New Orleans Medical and Surgical Journal*, April, 1880.

This excellent little book is the first work of a distinguished pupil of Jonathan Hutchinson; it recommends itself above all by its clearness, method, and precision.—*Paris Annales de Dermatologie et de Syphiligraphie*, 25 April, 1880.

FOX (TILBURY), M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,

Physician to the Department for Skin Diseases, University College Hospital.

EPITOME OF SKIN DISEASES. WITH FORMULÆ. FOR STUDENTS AND PRACTITIONERS. Second edition, thoroughly revised and greatly enlarged. In one very handsome 12mo. volume of 216 pages. Cloth, $1 88. (*Just Issued.*)

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Hospital Med. College, N. Y.

A MANUAL OF PERCUSSION AND AUSCULTATION; of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. Second edition. In one handsome royal 12mo. volume; cloth, $1 63. (*Just Ready.*)

Prof. Flint is so well known as a medical teacher and writer that it seems superfluous to state that the subject has been treated in a thorough and systematic manner. In revising it for a second edition the author has confined himself to such additions as seem likely to render it more useful, not only to students engaged in the practical study of the subject, but also to practitioners as a hand book for ready reference, and we do not hesitate in saying that it would prove a valuable addition to every physician's library.—*Med. and Surg. Reporter*, March 13, 1880.

The little work before us has already become a standard one, and has become extensively adopted as a text-book. There is certainly none better. It contains the substance of the lessons which the author has for many years given, in connection with practical instruction in auscultation and percussion, to private classes, composed of medical students and practitioners.—*Cincinnati Med. News*, Feb. 1880.

BY THE SAME AUTHOR.

PHTHISIS: ITS MORBID ANATOMY, ETIOLOGY, SYMPTOMATIC EVENTS AND COMPLICATIONS, FATALITY AND PROGNOSIS, TREATMENT, AND PHYSICAL DIAGNOSIS; in a series of Clinical Studies. By AUSTIN FLINT, M.D., Prof. of the Principles and Practice of Medicine in Bellevue Hospital Med. College, New York. In one handsome octavo volume: $3 50. (*Lately Issued.*)

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART. Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate, cloth, $4.

Dr. Flint chose a difficult subject for his researches, and has shown remarkable powers of observation and reflection, as well as great industry, in his treatment of it. His book must be considered the fullest and clearest practical treatise on those subjects, and should be in the hands of all practitioners and students. It is a credit to American medical literature.—*Amer. Journ. of the Med. Sciences*, July, 1860.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS. Second and revised edition. In one handsome octavo volume of 595 pages, cloth, $4 50.

BROWN (LENNOX), F.R.C.S. Ed.,

Senior Surgeon to the Central London Throat and Ear Hospital, etc.

THE THROAT AND ITS DISEASES. With one hundred Typical Illustrations in colors, and fifty wood engravings, designed and executed by the author. In one very handsome imperial octavo volume of 351 pages; cloth, $5 00. (*Just Ready.*)

SEILER (CARL), M.D.,

Lecturer on Laryngoscopy at the Univ. of Penna., Chief of the Throat Dispensary at the Univ. Hospital, Phila., etc.

HANDBOOK OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NASAL CAVITIES. In one handsome royal 12mo. volume, of 156 pages, with 35 illustrations; cloth, $1. (*Just Ready.*)

We most heartily commend this book as showing sound judgment in practice, and perfect familiarity with the literature of the specialty it so ably epitomizes.—*Philada. Med. Times*, July 5, 1879.

A convenient little handbook, clear, concise, and accurate in its method, and admirably fulfilling its purpose of bringing the subject of which it treats within the comprehension of the general practitioner.—*N. C. Med. Jour.*, June, 1879.

WILLIAMS'S PULMONARY CONSUMPTION; its Nature, Varieties, and Treatment. With an Analysis of One Thousand Cases to exemplify its duration. In one neat octavo volume of about 350 pages; cloth, $2 50.

SLADE ON DIPHTHERIA; its Nature and Treatment, with an account of the History of its Prevalence in various Countries. Second and revised edition. In one neat royal 12mo. volume, cloth, $1 25.

WALSHE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Third American Edition. In 1 vol. 8vo., 420 pp., cloth, $3 00.

CHAMBERS'S MANUAL OF DIET AND REGIMEN IN HEALTH AND SICKNESS. In one handsome octavo volume. Cloth, $2 75.

LA ROCHE ON PNEUMONIA. 1 vol. 8vo., cloth, of 500 pages. Price, $3 00.

WILSON'S STUDENT'S BOOK OF CUTANEOUS MEDICINE and DISEASES OF THE SKIN. In one very handsome royal 12mo. volume. $3 50.

FULLER ON DISEASES OF THE LUNGS AND AIR-PASSAGES. Their Pathology, Physical Diagnosis, Symptoms, and Treatment. From the second and revised English edition. In one handsome octavo volume of about 500 pages: cloth, $3 50.

SMITH ON CONSUMPTION; ITS EARLY AND REMEDIABLE STAGES. 1 vol. 8vo., pp. 254. $2 25.

BASHAM ON RENAL DISEASES: a Clinical Guide to their Diagnosis and Treatment. With Illustrations. In one 12mo. vol. of 304 pages, cloth, $2 00.

LECTURES ON THE STUDY OF FEVER. By A. HUDSON, M.D., M.R.I.A., Physician to the Meath Hospital. In one vol. 8vo., cloth, $2 50.

A TREATISE ON FEVER. By ROBERT D. LYONS, K.C.C. In one octavo volume of 362 pages, cloth $2 25.

HILLIER'S HANDBOOK OF SKIN DISEASES, for Students and Practitioners. Second Am. Ed. In one royal 12mo. vol. of 358 pp. With illustrations. Cloth, $2 25.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,
Professor of Venereal Diseases at the Col. of Phys. and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES.

Including the results of recent investigations upon the subject. Fourth edition, revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of New York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome octavo volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half Russia, $6 25. (*Just Ready.*)

This work, on its first appearance, immediately took the position of a standard authority on its subject wherever the language is spoken, and the success of an Italian translation shows that it is regarded with equal favor on the Continent of Europe. In repeated editions the author labored sedulously to render it more worthy of its reputation, and in the present revision no pains have been spared to perfect it as far as possible. Several years having elapsed since the publication of the third edition, much material has been accumulated during the interval by the industry of syphilologists, and new views have been enunciated. All this so far as confirmed by observation and experience, has been incorporated; many portions of the volume been rewritten, the series of illustrations has been enlarged and improved, and the whole may be regarded rather as a new work than as a new edition. It is confidently presented as fully on a level with the most advanced condition of syphilology, and as a work to which the practitioner may refer with the certainty of finding clearly and succinctly set forth whatever falls within the scope of such a treatise.

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and, we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.—*Archives of Medicine*, April, 1880.

This now classical work on venereal disease comes to us in its fourth edition rewritten, enlarged, and materially improved in every way. Dr. Taylor, as we had every reason to expect, has performed this part of his work with unusual excellence. We feel that what has been written has done but scanty justice to the merits of this truly great treatise.—*St. Louis Courier of Medicine*, Feb. 1880.

We find that we have here practically a new book—that the statement of the title-page, as to the fact that it has been largely rewritten, is a sufficiently modest announcement for the important changes in the text. After a thorough examination of the present edition, we can assert confidently that the enormous labor we have described has been here most faithfully and conscientiously performed.—*Amer. Journ. Med. Sci.*, Jan. 1880.

It is one of the best general treatises on venereal diseases with which we are acquainted, and is especially to be recommended as a guide to the treatment of syphilis.—*London Practitioner*, March, 1880.

CULLERIER (A.), ***and*** ***BUMSTEAD (FREEMAN J.).***
Surgeon to the Hôpital du Midi. *Professor of Venereal Diseases in the College of Physicians and Surgeons, N. Y.*

AN ATLAS OF VENEREAL DISEASES.

Translated and Edited by FREEMAN J. BUMSTEAD. In one large imperial 4to. volume of 328 pages, double-columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life; strongly bound in cloth, $17 00; also, in five parts, stout wrappers, at $3 per part.

Anticipating a very large sale for this work, it is offered at the very low price of THREE DOLLARS a Part, thus placing it within the reach of all who are interested in this department of practice. Gentlemen desiring early impressions of the plates would do well to order it without delay. A specimen of the plates and text sent free by mail, on receipt of 25 cents.

LEE'S LECTURES ON SYPHILIS AND SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. In one handsome octavo volume; cloth, $2 25.

HILL ON SYPHILIS AND LOCAL CONTAGIOUS DISORDERS. **In one handsome octavo volume; cloth $3 25.**

WEST (CHARLES), M.D.,
Physician to the Hospital for Sick Children, London, &c.

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD.

Fifth American from the sixth revised and enlarged English edition. In one large and handsome octavo volume of 678 pages. Cloth, $4 50; leather, $5 50. (*Lately Issued.*)

BY THE SAME AUTHOR. (*Lately Issued.*)

ON SOME DISORDERS OF THE NERVOUS SYSTEM IN CHILDHOOD;

being the Lumleian Lectures delivered at the Royal College of Physicians of London, in March, 1871. In one volume small 12mo., cloth, $1 00.

BY THE SAME AUTHOR.

LECTURES ON THE DISEASES OF WOMEN.

Third American, from the Third London edition. In one neat octavo volume of about 550 pages, cloth, $3 75; leather, $4 75.

SMITH (*J. LEWIS*), *M.D.*,

Clinical Professor of Diseases of Children in the Bellevue Hospital Med. College, N Y.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN.

Fourth Edition, revised and enlarged. In one handsome octavo volume of about 750 pages, with illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*New Ready.*)

The very marked favor with which this work has been received wherever the English language is spoken, has stimulated the author, in the preparation of the Fourth Edition, to spare no pains in the endeavor to render it worthy in every respect of a continuance of professional confidence. Many portions of the volume have been rewritten, and much new matter introduced, but by an earnest effort at condensation, the size of the work has not been materially increased.

In the period which has elapsed since the third edition of the work, so extensive have been the advances that whole chapters required to be rewritten, and hardly a page could pass without some material correction or addition. This labor has occupied the writer closely, and he has performed it conscientiously, so that the book may be considered a faithful portraiture of an exceptionally wide clinical experience in infantile diseases, corrected by a careful study of the recent literature of the subject.—*Med. and Surg. Reporter*, April 5, 1879.

It is scarcely necessary for us to say the work before us is a standard work upon diseases of children, and that no work has a higher standing than it upon those affections. In consequence of its thorough revision, the work has been made of more value than ever, and may be regarded as fully abreast of the times. We cordially commend it to students and physicians. There is no better work in the language on diseases of children.—*Cincinnati Med. News*, March, 1879.

The author has evidently determined that it shall not lose ground in the esteem of the profession for want of the latest knowledge on that important department of medicine. He has accordingly incorporated in the present edition the useful and practical results of the latest study and experience, both American and foreign, especially those bearing on therapeutics. Altogether the book has been greatly improved, while it has not been greatly increased in size.—*New York Medical Journal*, June, 1879.

This excellent work is so well known that an extended notice at this time would be superfluous. The author has taken advantage of the demand for another new edition to revise in a most careful manner the entire book; and the numerous corrections and additions evince a determination on his part to keep fully abreast with the rapid progress that is being made in the knowledge and treatment of children's diseases. By the adoption of a somewhat closer type, an increase in size of only thirty pages has been necessitated by the new subject matter introduced.—*Boston Med. and Surg. Jour.*, May 29, 1879.

Probably no other work ever published in this country upon a medical subject has reached such a heighth of popularity as has this well-known treatise. As a text and reference-book it is pre-eminently the authority upon diseases of children. It stands deservedly higher in the estimation of the profession than any other work upon the same subject.—*Nashville Journ. of Med. and Surg.*, May, 1879.

SWAYNE (*JOSEPH GRIFFITHS*), *M.D.*,

Physician-Accoucheur to the British General Hospital, &c.

OBSTETRIC APHORISMS FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE.

Second American, from the Fifth and Revised London Edition with Additions by E. R. HUTCHINS, M.D. With Illustrations. In one neat 12mo. volume. Cloth, $1 25. (*Lately Issued.*)

⁂ See p. 3 of this Catalogue for the terms on which this work is offered as a premium to subscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

CHURCHILL ON THE PUERPERAL FEVER AND OTHER DISEASES PECULIAR TO WOMEN. 1 vol. 8vo., pp. 450, cloth. $2 50.

DEWEES'S TREATISE ON THE DISEASES OF FEMALES. With illustrations. Eleventh Edition with the Author's last improvements and corrections. In one octavo volume of 536 pages, with plates, cloth. $3 00.

MEIGS ON THE NATURE, SIGNS, AND TREATMENT OF CHILDBED FEVER. 1 vol. 8vo., pp. 365, cloth. $2 00.

ASHWELL'S PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN. Third American, from the Third and revised London edition. 1 vol. 8vo., pp. 528, cloth. $3 50.

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Obstetrics, &c., in the University of Pennsylvania.

ON DISEASES PECULIAR TO WOMEN; including Displacements of the Uterus.

With original illustrations. Second edition, revised and enlarged. In one beautifully printed octavo volume of 531 pages, cloth, $4 50.

CHURCHILL (*FLEETWOOD*), *M.D., M.R.I.A.*

ON THE THEORY AND PRACTICE OF MIDWIFERY.

A new American from the fourth revised and enlarged London edition. With notes and additions by D. FRANCIS CONDIE, M.D., author of a "Practical Treatise on the Diseases of Children," &c. With one hundred and ninety four illustrations. In one very handsome octavo volume of nearly 700 large pages. Cloth, $4 00; leather, $5 00.

MONTGOMERY'S EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY. With two exquisite colored plates, and numerous wood-cuts. In 1 vol. 8vo., of nearly 600 pp., cloth, $3 75.

CONDIE'S PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Sixth edition, revised and augmented. In one large octavo volume of nearly 800 closely-printed pages, cloth, $5 25; leather, $6 25.

RIGBY'S SYSTEM OF MIDWIFERY. With notes and Additional Illustrations. Second American edition. One volume octavo, cloth 422 pages, $2 50.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American, from the second revised and enlarged English edition. In one handsome octavo volume, cloth, $2 50.

THOMAS (T. GAILLARD), M.D.,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 850 pages, with about 270 illustrations. (*In Press.*)

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology. The work embodies not only its author's large experience, but reflects his careful study among other authorities in this branch, both at home and abroad. Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won.—*Md. Med. Journ.*, Nov. 15, 1880.

BARNES (ROBERT), M.D., F.R.C.P.,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN. Second American, from the Second Enlarged and Revised English Edition. In one handsome octavo volume, of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

The call for a new edition of Dr. Barnes's work on the Diseases of Females has encouraged the author to make it even more worthy of the favor of the profession than before. By a rearrangement and careful pruning space has been found for a new chapter on the Gynæcological Relations of the Bladder and Bowel Disorders, without increasing the size of the book, while many new illustrations have been introduced where experience has shown them to be needed. It is therefore hoped that the volume will be found to reflect thoroughly and accurately the present condition of gynæcological science.

Dr Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

We pity the doctor who, having any considerable practice in diseases of women, has no copy of "Barnes" for daily consultation and instruction. It is at once a book of great learning, research, and individual experience, and at the same time eminently practical. That it has been appreciated by the profession, both in Great Britain and in this country, is shown by the second edition following so soon upon the first.—*Am. Practitioner*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 628 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be largely consulted by the profession.—*Am. Supp. Obstetrical Journ. Gt. Britain and Ireland*, Oct. 1878.

No other gynæcological work holds a higher position, having become an authority everywhere in diseases of women. The work has been brought fully abreast of present knowledge. Every practitioner of medicine should have it upon the shelves of his library, and the student will find it a superior text-book.—*Cincinnati Med. News*, Oct. 1878.

This second revised edition, of course, deserves all the commendation given to its predecessor, with the additional one that it appears to include all or nearly all the additions to our knowledge of its subject that have been made since the appearance of the first edition. The American references are, for an English work, especially full and appreciative, and we can cordially recommend the volume to American readers.—*Journ. of Nervous and Mental Disease*, Oct. 1878.

This second edition of Dr. Barnes's great work comes to us containing many additions and improvements which bring it up to date in every feature. The excellences of the work are too well known to require enumeration, and we hazard the prophecy that they will for many years maintain its high position as a standard text-book and guide book for students and practitioners.—*N. O. Med. Journ.*, Oct. 1878.

CHADWICK (JAMES R.), A.M., M.D.

A MANUAL OF THE DISEASES PECULIAR TO WOMEN. In one neat volume, royal 12mo., with illustrations. (*Preparing.*)

EMMET (THOMAS ADDIS), M.D.

Surgeon to the Woman's Hospital, New York, etc.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thorougly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to the author as an evidence that his labors have proved acceptable, has in a great measure heightened his sense of responsibility. He has therefore endeavored to take full advantage of the opportunity afforded to him for its revision. Every page has received his earnest scrutiny; the criticisms of his reviewers have been carefully weighed; and while no marked increase has been made in the size of the volume, several portions have been rewritten, and much new matter has been added. In this minute and thorough revision, the labor involved has been much greater than is perhaps apparent in the results, but it has been cheerfully expended in the hope of rendering the work more worthy of the favor which has been accorded to it by the profession.

In no country of the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticize, with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.*, Feb. 21, 1880.

No gynæcological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med. Gaz.*, April 5, 1880.

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz.*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

DUNCAN (J. MATTHEWS), M.D., LL.D., F.R.S.E., etc.

CLINICAL LECTURES ON THE DISEASES OF WOMEN, Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 pages. Cloth, $1 50. (*Just Ready.*)

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journ.*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

RAMSBOTHAM (FRANCIS H.), M.D.

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00.

WINCKEL (F.),

Professor and Director of the Gynæcological Clinic in the University of Rostock.

A COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED, for Students and Practitioners. Translated, with the consent of the author, from the Second German Edition, by JAMES READ CHADWICK, M.D. In one octavo volume. Cloth, $4 00. (*Lately Issued.*)

TANNER (THOMAS H.), M.D.

ON THE SIGNS AND DISEASES OF PREGNANCY. First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.

PLAYFAIR (W. S.), M.D., F.R.C.P.,

Professor of Obstetric Medicine in King's College, etc. etc.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY.

Third American edition, revised by the author. Edited, with additions, by Robert P. Harris, M.D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready*.)

EXTRACT FROM THE AUTHOR'S PREFACE.

The second American edition of my work on Midwifery being exhausted before the corresponding English edition, I cannot better show my appreciation of the kind reception my book has received in the United States than by acceding to the publisher's request that I should myself undertake the issue of a third edition. As little more than a year has elapsed since the second edition was issued, there are naturally not many changes to make, but I have, nevertheless, subjected the entire work to careful revision, and introduced into it a notice of most of the more important recent additions to obstetric science. To the operation of gastro-elytrotomy—formerly described along with the Cæsarean section—I have now devoted a separate chapter. The editor of the Second American edition, Dr. Harris, enriched it with many valuable notes, of which, it will be observed, I have freely availed myself.

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy. The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence*, we would undoubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880

It certainly is an admirable exposition of the Science and Practice of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880

BARNES (FANCOURT), M.D.,

Physician to the General Lying-in Hospital, London.

A MANUAL OF MIDWIFERY FOR MIDWIVES AND MEDICAL STUDENTS.

With 50 illustrations. In one neat royal 12mo. volume of 200 pages; cloth, $1 25. (*Now Ready*.)

The book is written in plain, and as far as possible in untechnical language. Any intelligent midwife or medical student can easily comprehend the directions. It will undoubtedly fill a want, and will be popular with those for whom it has been prepared. The examining questions at the back will be found very useful.—*Cincinnati Med. News*, Aug. 1879.

THE OBSTETRICAL JOURNAL. (*Free of postage for* 1880.)

THE OBSTETRICAL JOURNAL of Great Britain and Ireland;

Including Midwifery, and the Diseases of Women and Infants. A monthly of 64 octavo pages, very handsomely printed. Subscription, Three Dollars per annum. Single Numbers, 25 cents each.

With the January number will terminate Vol. VII. of the Obstetrical Journal. The first No. of Vol. VIII. will be issued about Feb. 1st; the "American Supplement" of 16 pages per No. will be discontinued, and the periodical will thenceforth consist of 64 pages per number, at the exceedingly low price of Three Dollars per annum, free of postage. For this trifling sum the subscriber will thus obtain more than 750 pages per annum, containing an extent and variety of information which may be estimated from the fact that Vol. VI. of the "Obstetrical Journal" contains in

Original Communications . .	44 Articles
Hospital Practice	4 "
General Correspondence . .	5 "
Reviews of Books	9 "
Proceedings of Societies . .	101 "
In Monthly Summary, Obstetric	73 "
In Monthly Summary, Gynæcic	28 Articles
" " Pediatric	4 "
News	9 "
	241

and that it numbers among its contributors the distinguished names of Lombe Atthill, J. H. Aveling, Robert Barnes, J. Henry Bennet, Nathan Bozeman, Thomas Chambers, Fleetwood Churchill, Charles Clay, John Clay, J. Matthews Duncan, Arthur Farre, Robert Greenhalgh, W. M. Graily Hewitt, J. Braxton Hicks, William Leishman, Angus Macdonald, Alfred Meadows, Alex. Simpson, J. G. Swayne, Lawson Tait, Edward J. Tilt, E. H. Trenholme, T. Spencer Wells, Arthur Wigglesworth, and many other distinguished practitioners. Under such auspices it has amply fulfilled its object of presenting to the physician all that is new and interesting in the rapid development of obstetrical and gynæcological science.

As a very large increase in the subscription list is anticipated under this reduction in price, gentlemen who propose to subscribe, and subscribers intending to renew their subscriptions, are recommended to lose no time in making their remittances, as the limited number printed may at any time be exhausted.

LEISHMAN (WILLIAM), M.D.,

Regius Professor of Midwifery in the University of Glasgow, &c.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE.

Third American edition, revised by the Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia Hospital, &c. In one large and very handsome octavo volume, of 733 pages, with over two hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

Few works on this subject have met with as great a demand as this one appears to have. To judge by the frequency with which its author's views are quoted, and its statements referred to in obstetrical literature, one would judge that there are few physicians devoting much attention to obstetrics who are without it. The author is evidently a man of ripe experience and conservative views, and in no branch of medicine are these more valuable than in this.—*New Remedies*, Jan. 1880.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

The book is greatly improved, and as such will be welcomed by those who are trying to keep posted in the rapid advances which are being made in the study of obstetrics.—*Boston Med. and Surg Journ.*, Nov. 27, 1879.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise. To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

PARRY (JOHN S.), M.D.,

Obstetrician to the Philadelphia Hospital, Vice-Prest. of the Obstet. Society of Philadelphia.

EXTRA-UTERINE PREGNANCY: ITS CLINICAL HISTORY, DIAGNOSIS, PROGNOSIS, AND TREATMENT.

In one handsome octavo volume. Cloth, $2 50. (*Lately Issued.*)

HODGE (HUGH L.), M.D.,

Emeritus Professor of Midwifery, &c., in the University of Pennsylvania, &c.

THE PRINCIPLES AND PRACTICE OF OBSTETRICS.

Illustrated with large lithographic plates containing one hundred and fifty-nine figures from original photographs, and with numerous wood-cuts. In one large and beautifully printed quarto volume of 550 double-columned pages, strongly bound in cloth, $14.

The work of Dr. Hodge is something more than a simple presentation of his particular views in the department of Obstetrics; it is something more than an ordinary treatise on midwifery; it is, in fact, a cyclopædia of midwifery. He has aimed to embody in a single volume the whole science and art of Obstetrics. An elaborate text is combined with accurate and varied pictorial illustrations, so that no fact or principle is left unstated or unexplained.—*Am. Med. Times*, Sept. 3, 1864.

*** Specimens of the plates and letter-press will be forwarded to any address, free by mail, on receipt of six cents in postage stamps.

STIMSON (LEWIS A.), A.M., M.D.,

Surgeon to the Presbyterian Hospital.

A MANUAL OF OPERATIVE SURGERY.

In one very handsome royal 12mo. volume of about 500 pages, with 332 illustrations; cloth, $2 50. (*Just Issued.*)

The work before us is a well printed, profusely illustrated manual of over four hundred and seventy pages. The novice, by a perusal of the work, will gain a good idea of the general domain of operative surgery, while the practical surgeon has presented to him within a very concise and intelligible form the latest and most approved selections of operative procedure. The precision and conciseness with which the different operations are described enable the author to compress an immense amount of practical information in a very small compass.—*N. Y. Medical Record*, Aug. 3, 1878.

This volume is devoted entirely to operative surgery, and is intended to familiarize the student with the details of operations and the different modes of performing them. The work is handsomely illustrated, and the descriptions are clear and well drawn. It is a clever and useful volume; every student should possess one. The preparation of this work does away with the necessity of pondering over larger works on surgery for descriptions of operations, as it presents in a nut-shell just what is wanted by the surgeon without an elaborate search to find it.—*Md. Med Journal*, Aug. 1878.

The author's conciseness and the repleteness of the work with valuable illustrations entitle it to be classed with the text-books for students of operative surgery, and as one of reference to the practitioner.—*Cincinnati Lancet and Clinic*, July 27, 1878.

SKEY'S OPERATIVE SURGERY. In 1 vol. 8vo. cl., of 650 pages; with about 100 wood-cuts. $3 25

COOPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY In 1 vol. 8vo cl'h. 750 p. $2.

GIBSON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edit'n, improved and altered. With thirty-four plates. In two handsome octavo volumes, about 1000 pp., leather, raised bands. $6 50.

THE PRINCIPLES AND PRACTICE OF SURGERY. By WILLIAM PIRRIE, F.R.S.E., Profes'r of Surgery in the University of Aberdeen. Edited by JOHN NEILL, M.D., Professor of Surgery in the Penna. Medical College, Surg'n to the Pennsylvania Hospital, &c. In one very handsome octavo vol. of 780 pages, with 316 illustrations, cloth, $3 75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American, from the Third Edinburgh Edition. In one large 8vo. vol. of 700 pages, with 340 illustrations, cloth, $3 75.

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition. Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (SAMUEL D.), M.D.,
Professor of Surgery in the Jefferson Medical College of Philadelphia.

SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic, and Operative.

Illustrated by upwards of Fourteen Hundred Engravings. Fifth edition, carefully revised, and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

The continued favor, shown by the exhaustion of successive large editions of this great work, proves that it has successfully supplied a want felt by American practitioners and students. In the present revision no pains have been spared by the author to bring it in every respect fully up to the day. To effect this a large part of the work has been rewritten, and the whole enlarged by nearly one-fourth, notwithstanding which the price has been kept at its former very moderate rate. By the use of a close, though very legible type, an unusually large amount of matter is condensed in its pages, the two volumes containing as much as four or five ordinary octavos. This, combined with the most careful mechanical execution, and its very durable binding renders it one of the cheapest works accessible to the profession. Every subject properly belonging to the domain of surgery is treated in detail, so that the student who possesses this work may be said to have in it a surgical library.

We have now brought our task to a conclusion, and have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together that the busy practitioner, when in difficulty, can at once find the information he requires. His work, on the contrary, is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares.*" It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid, instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition, and arrangement of acquired knowledge and personal experience.—*N.Y. Med. Journ.*, Feb. 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St. Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor, and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research.—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES,

and Malformations of the Urinary Bladder, the Prostate Gland, and the Urethra. Third Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with 170 illustrations: cloth, $4 50. (*Just Issued.*)

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct. 1876.

It is with pleasure we now again take up this old work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture' is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES.

In 1 vol. 8vo., with illustrations, pp. 468, cloth, $2 75.

DRUITT (ROBERT), M.R.C.S., &c.

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY.

A new and revised American, from the eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

All that the surgical student or practitioner could desire.—*Dublin Quarterly Journal.*

It is a most admirable book. We do not know when we have examined one with more pleasure.—*Boston Med. and Surg. Journal.*

In Mr. Druitt's book, though containing only some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic. We have examined the book most thoroughly, and can say that this success is well merited. His book moreover, possesses the inestimable advantages of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Sciences*

HAMILTON (FRANK H.) M.D., LL.D.

Surgeon to the Bellevue Hospital, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS.

Sixth edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5.50; leather, $6.50; half Russia, raised bands, $7 00.

The demand which has so speedily exhausted five large editions of this work, shows that the author has succeeded in supplying a want, felt by the profession at large, of an exhaustive treatise on a frequent and troublesome class of accidents. The unanimous voice of the profession abroad, as well as at home, has pronounced it the most complete work to which the surgeon can refer for information respecting the details of the subject. In the preparation of this new edition, the author has added a chapter on General Prognosis; that on Fractures of the Patella has been entirely rewritten, in order that the results of a recent exhaustive study of this subject might be given, and, in fact, the entire matter of the book has undergone most thorough revision. A number of illustrations have been omitted to make place for new ones, and a few have been inserted from the German edition, published at Göttingen in 1877.

A few notices of the previous edition are appended.

The volume before us is (we say it with a pang of wounded patriotism) the best and handiest book on the subject in the English language. It is in vain to attempt a review of it; nearly as vain to seek for any sins, either of commission or omission.—*Edinburgh Med. and Surg. Journal.*

From the great labor and time bestowed upon its preparation, we had been led to anticipate a very thorough and elaborate monograph, and an attentive perusal of its pages has satisfied us that our expectations have been fully realized. The work is by far the most complete disquisition on fractures and dislocations in the English language. It is not our intention to present anything like a formal analysis of this work; to do so would carry us far beyond the limits which we have assigned to us, to say nothing of the fact that it would be a matter of supererogation, inasmuch as no intelligent practitioner will be likely to be without a copy of it for ready use. No library, however extensive, will be complete without it.—*North American Medico-Chirurgical Review.*

This is a valuable contribution to the surgery of most important affections, and is the more welcome, inasmuch as at the present time we do not possess a single complete treatise on Fractures and Dislocations in the English language. It has remained for our American brother to produce a complete treatise upon the subject.—*London Lancet.*

As every one knows, this is the most complete and reliable work on the subjects of which it treats published in any language, not even excepting Malgaigne's excellent and standard treatise. Hence it would be a waste of time and space further to attempt to convince our readers of its excellences. It remains only for us to add that, in every respect this fifth edition has been thoroughly revised, and contains some fifty pages of new matter more than the fourth edition.—*Va. Med. Monthly*, Jan. 1876.

For thoroughness, for completeness of detail, and for clearness of illustration, this work is without its equal—without a rival indeed—in its department of the medical literature of our language. Its value is enhanced by the artistic skill displayed in the mechanical execution of the volume.—*Pacific Med. and Surg. Journ.*, Jan. 1876.

There is no better work on the subject in existence than that of Dr. Hamilton. It should be in the possession of every general practitioner and surgeon.—*The Am. Journ. of Obstetrics*, Feb. 1876.

ASHHURST (JOHN, Jr.), M.D.,

Prof. of Clinical Surgery, Univ. of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY.

Second edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7.50. (*Just Ready.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

The attempt to embrace in a volume of 1000 pages the whole field of surgery, general and special, would be a hopeless task unless through the most tireless industry in collating and arranging, and the wisest judgment in condensing and excluding. These facilities have been abundantly employed by the author, and he has given us a most excellent treatise, brought up by the revision for the second edition to the latest date. Of course this book is not designed for specialists, but as a course of general surgical knowledge and for general practitioners, and as a text-book for students it is not surpassed by any that has yet appeared, whether of home or foreign authorship.—*N. Carolina Med. Journal*, Jan. 1879.

Ashhurst's Surgery is too well known in this country to require special commendation from us. This, its second edition, enlarged and thoroughly revised, brings it nearer our idea of a model text-book than any recently published treatise. Though numerous additions have been made, the size of the work is not materially increased. The main trouble of text-books of modern times is, that they are too cumbersome. The student needs a book which will furnish him the most information in the shortest time. In every respect this work of Ashhurst is the model text-book—full, comprehensive and compact.—*Nashville Jour. of Med. and Surg.*, Jan. '79.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

BRYANT (THOMAS), F.R.C.S.,
Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY. Third American, from the Second and Revised English Edition. Thoroughly revised and much improved, by John B Roberts, M.D. In one large and very handsome imperial octavo volume of over 1050. pages, with 672 illustrations. (*In Press.*)

The marked success of this work on both sides of the Atlantic shows that the author has succeeded in the effort to give the student and practitioner a sound and trustworthy guide in the practice of surgery.

In preparing a new edition, it has seemed best, in order to adapt the work more thoroughly to the needs of the native student, that it should receive the benefits of a revision by an American editor, who should not only incorporate the most recent discoveries, but also the modes of procedure, which must necessarily vary with the practices of different countries.

The work is now confidently presented as worthy a continuance of the very distinguished success which has marked the reception of the previous editions.

ERICHSEN (JOHN E.),
Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases, and Operations. Carefully revised by the author from the Seventh and enlarged English Edition. Illustrated by eight hundred and sixty two engravings on wood. In two large and beautiful octavo volumes of nearly 2000 pages: cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am Practitioner*, April, 1878.

It is no idle compliment to say that this is the best edition Mr. Erichsen has ever produced of his well-known book. Besides inheriting the virtues of its predecessors, it possesses excellences quite its own. Having stated that Mr. Erichsen has incorporated into this edition every recent improvement in the science and art of surgery, it would be a supererogation to give a detailed criticism. In short, we unhesitatingly aver that we know of no other single work where the student and practitioner can gain at once so clear an insight into the principles of surgery, and so complete a knowledge of the exigencies of surgical practice.—*London Lancet*, Feb. 14, 1878

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

Of the many treatises on Surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject, and vast clinical experience qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, we observe that much old matter has been omitted. The entire work has been thoroughly written up, and not merely amended by a few extra chapters A great improvement has been made in the illustrations. One hundred and fifty new ones have been added, and many of the old ones have been redrawn. The author highly appreciates the favor with which his work has been received by American surgeons, and has endeavored to render his latest edition more than ever worthy of their approval. That he has succeeded admirably, must, we think, be the general opinion. We heartily recommend the book to both student and practitioner.—*N. Y. Med. Journal*, Feb. 1878.

HOLMES (TIMOTHY), M.D.,
Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE. In one handsome octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7: half Russia, $7 50. (*Just Issued.*)

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has not the time to give attention to more minute and extended works and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincinnati Med. News*, April, 1876.

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the fourth and enlarged London Edition. With illustrations. In one 8vo. vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with an additional chapter on Military Surgery. One 12mo. vol. of 383 pages with 184 wood-cuts Cloth, $1 75.

WELLS (J. SOELBERG),

Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American, from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates Together with selections from the Test-types of Jaeger and Snellen In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6.50. (*Just Ready.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

It is with great pleasure that we welcome a new edition of this standard work on ophthalmology. The American editor has taken great pains to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision in 1873.—*Phila. Med. and Surg. Reporter*, Oct. 23, 1880.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

NETTLESHIP (EDWARD), F.R.C.S.,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St Thomas' Hospital. London.

MANUAL OF OPHTHALMIC MEDICINE. In one royal 12mo. volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The book is written in a careful and logical manner, and though extremely concise, we have failed to notice any evidence of ambiguity. It is rendered more compact and homogeneous by frequent references, by page number, to other portions of the work; repetitions are thus avoided, and we have been surprised to find how much information our author has succeeded in conveying in so small a space. A careful study of the book will well repay the general practitioner, even though it should serve only as a *monitor*. It is particularly useful in the latter regard, as the subject of treatment is presented in a thoroughly conservative manner.—*N Y. Med. Record*, March 6, 1880.

The author has succeeded in touching upon about all the points, operations, diseases of the eye in relation to general diseases, and has prepared a very acceptable book.—*Cincinnati Lancet and Clinic*, Feb. 7, 1880.

It is *multum in parvo*, containing all the leading points to be remembered in the pathology, description, and treatment of diseases of the eye. It will be found especially valuable in preparing for examinations Practitioners will find it convenient as a work of reference, when they wish to refresh their memories in respect to the features of some affections.—*Cincinnati Med. News*, Jan 1880.

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

CARTER (R. BRUDENELL), F.R.C.S.,

Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE. Edited, with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75. (*Just Issued.*)

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the use and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (EDGAR A.),

Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE. Being Elementary Instructions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1. (*Now Ready.*)

LAURENCE'S HANDY-BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged With numerous illustrations. In one very handsome octavo volume, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT, AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A., M.D.,

Aural Surg. to the Presb. Hosp., Surgeon-in-charge of the Infir. for Dis. of the Ear, Phila.

THE EAR, ITS ANATOMY, PHYSIOLOGY, AND DISEASES.

A Practical Treatise for the Use of Medical Students and Practitioners. In one handsome octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; leather, $5 50; half Russia, $6 00. (*Now Ready.*)

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Tröltsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work, which as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well repay the busy practitioner in the pleasure he will derive from the agreeable style in which many otherwise dry and mostly unknown subjects are treated. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will, we hope, be proportionate to the amount of benefit he can obtain from the careful study of the book, and a constant reference to its trustworthy pages.—*Edinburgh Med. Jour.*, Aug. 1878.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

A MANUAL OF MEDICAL JURISPRUDENCE.

Eighth American edition. Edited by JOHN J. REESE, M.D., Prof. of Med. Jurisp. and Toxicology in the Univ. of Penn. In one large octavo volume of 933 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50.

The editor of the present American issue of Dr. Taylor's well known work on Medical Jurisprudence takes occasion to express his deep sense of the loss sustained by the professions of both law and medicine in the recent death of its lamented author.

This revision, undertaken expressly for the benefit of his American brethren, proved his last work; almost immediately after its completion was he summoned from the sphere of his earthly labors.

Dr. Taylor's additions, scattered throughout the volume, will be found quite numerous, serving to place this record of the progress of the science of Medical Jurisprudence thoroughly on a level with the latest experience and research. The editor may, therefore, congratulate the medico-legal student that he has had the good fortune to secure these valuable additions from the now departed master.

As was the case in the last American issue, the editor has deemed it wise to enlarge occasionally upon certain subjects with materials selected from the author's larger work, "The Principles and Practice of Medical Jurisprudence," a book to which every reader may not have ready access. The valuable notes of the former editors, Dr. Hartshorne and Judge Penrose, have, for the most part, been retained. They will be found inclosed in brackets, and distinguished by letters [H] and [P]. Those of the present editor are designated by the letter [R].

The hope is therefore expressed that the volume may be found worthy of a continuance of the favor which has carried it to an eighth edition, and has caused it to be regarded as a standard authority on all the subjects embraced within its scope.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE.

Second Edition, Revised, with numerous Illustrations. In two large octavo volumes, cloth, $10 00; leather, $12 00.

This great work is now recognized in England as the fullest and most authoritative treatise on every department of its important subject. In laying it, in its improved form, before the American profession, the publishers trust that it will assume the same position in this country.

BY THE SAME AUTHOR.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE.

Third American, from the Third and Revised English Edition. In one large octavo volume of 850 pages; cloth, $5 50; leather, $6 50. (*Just Issued.*)

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal investigations.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the compilation of this volume, stores of learning, experience, and practical acquaintance with his subject, probably far beyond what any other living authority on toxicology could have amassed or utilized. He has fully sustained his reputation by the consummate skill and legal acumen he has displayed in the arrangement of the subject-matter, and the result is a work on Poisons which will be indispensable to every student or practitioner in law and medicine.—*The Dublin Journ. of Med. Sci.*, Oct., 1875.

ROBERTS (WILLIAM), M.D.,

Lecturer on Medicine in the Manchester School of Medicine, etc.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

THOMPSON (SIR HENRY),

Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25. (*Just Issued.*)

BY THE SAME AUTHOR.

ON THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50. (*Lately Published.*)

TUKE (DANIEL HACK), M.D.,

Joint author of "The Manual of Psychological Medicine," &c.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25. (*Lately Issued.*)

BLANDFORD (G. FIELDING), M.D., F.R.C.P.,

Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

INSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

It satisfies a want which must have been sorely felt by the busy general practitioners of this country. It takes the form of a manual of clinical description of the various forms of insanity, with a description of the mode of examining persons suspected of insanity. We call particular attention to this feature of the book, as giving it a unique value to the general practitioner. If we pass from theoretical considerations to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

LEA (HENRY C.).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL, AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that should not be most carefully studied, and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

The appearance of a new edition of Mr. Henry C. Lea's "Superstition and Force" is a sign that our highest scholarship is not without honor in its native country. Mr. Lea has met every fresh demand for his work with a careful revision of it, and the present edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

BY THE SAME AUTHOR. (*Lately Published.*)

STUDIES IN CHURCH HISTORY—THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75.

The story was never told more calmly or with greater learning or wiser thought. We doubt, indeed, if any other study of this field can be compared with this for clearness, accuracy, and power.—*Chicago Examiner*, Dec. 1870.

Mr. Lea's latest work, "Studies in Church History," fully sustains the promise of the first. It deals with three subjects—the Temporal Power, Benefit of Clergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

TAYLOR'S MEDICAL JURISPRUDENCE—New Edition—Just Ready.

A MANUAL OF MEDICAL JURISPRUDENCE. By Alfred S. Taylor, M.D., late Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital, London. Eighth American edition. Edited by John J. Reese, M.D., Professor of Medical Jurisprudence and Toxicology in the Univ. of Penna. In one large and very handsome 8vo. vol. of 933 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50.

EXTRACT FROM THE EDITOR'S PREFACE.

The editor of the present American issue of Dr. Taylor's well-known work on Medical Jurisprudence takes occasion to express his deep sense of the loss sustained by the professions of both law and medicine in the recent death of its lamented author.

This revision, undertaken expressly for the benefit of his American brethren, proved his last work; almost immediately after its completion was he summoned from the sphere of his earthly labors.

Dr. Taylor's additions, scattered throughout the volume, will be found quite numerous, serving to place this record of the progress of the science of Medical Jurisprudence thoroughly on a level with the latest experience and research. The editor may, therefore, congratulate the medico-legal student that he has had the good fortune to secure these valuable additions from the now departed master.

As was the case in the last American issue, the editor has deemed it wise to enlarge occasionally upon certain subjects, with materials selected from the author's larger work, "The Principles and Practice of Medical Jurisprudence," a book to which every reader may not have ready access. The valuable notes of the former editors, Dr. Hartshorne and Judge Penrose, have, for the most part, been retained. They will be found inclosed in brackets, and distinguished by letters [H] and [P]. Those of the present editor are designated by the letter [R].

The hope is therefore expressed that the volume may be found worthy a continuance of the favor which has carried it to an eighth edition, and has caused it to be regarded as a standard authority on all the subjects embraced within its scope.

THOMAS ON WOMEN—New and Revised Edition—Just Ready.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. Gaillard Thomas, M.D., Professor of Obstetrics, etc., in the College of Physicians and Surgeons, New York. Fifth edition, thoroughly revised and rewritten. In one large and handsome 8vo. volume of over 850 pages, with about 270 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50.

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions, a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology. The work embodies not only its author's large experience, but reflects his careful study among other authorities in this branch, both at home and abroad. Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won.—*Md. Med. Journ.*, Nov. 15, 1880.

HAMILTON ON FRACTURES—New Edition—Just Ready.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. By Frank H. Hamilton, M.D., LL.D., Surgeon to Bellevue Hospital, N. Y., etc. Sixth edition, thoroughly revised and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5 50; leather, $6 50; half Russia, raised bands, $7 00.

The demand which has so speedily exhausted five large editions of this work, shows that the author has succeeded in supplying a want, felt by the profession at large, of an exhaustive treatise on a frequent and troublesome class of accidents. The unanimous voice of the profession abroad, as well as at home, has pronounced it the most complete work to which the surgeon can refer for information respecting the details of the subject. In the preparation of this new edition, the author has added a chapter on General Prognosis; that on Fractures of the Patella has been entirely rewritten, in order that the results of a recent exhaustive study of this subject might be given, and, in fact, the entire matter of the book has undergone most thorough revision. A number of illustrations have been omitted to make place for new ones, and a few have been inserted from the German edition, published at Göttingen in 1877.

HENRY C. LEA'S SON & CO., Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing the fourth year of its second half century, the publishers of the "American Journal of the Medical Sciences" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "The Medical News and Abstract," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of Five Dollars *per annum*.

The "News and Abstract" consists of sixty-four pages monthly, in a neat cover. It contains a Clinical Department in which will be continued the series of Original American Clinical Lectures, by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "Monthly Abstract," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an Editorial and a News Department, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "News and Abstract" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "American Journal of the Medical Sciences," to all who remit Five Dollars in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The American Journal of the Medical Sciences, published quarterly (1150 pages per annum), and The Medical News and Abstract published monthly (768 pages per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The American Journal of the Medical Sciences, when not paid for in advance,	Five Dollars.

The Medical News and Abstract, invariably in advance, Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the Journal (two annually) and the News and Abstract (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "Journal" and "News and Abstract" may be made at the risk of the publishers by forwarding in registered letters. Address
